For ten vaginal suppositories.

3. ℞.—Aristol,
Lard.....āā 5 grammes.
Lanoline..... 40 "
For pomade and ointment.

4. Solution of 10 per cent. in ether and oil of vaseline.

5. Can also be used as a medicinal soap.

℞.—Mutton suet..... 59.3
Olive oil..... 7.4
Caustic soda..... .... 22.2
Caustic potash at 380..... 11.1
100.0

Add Aristol dissolved in oil, 10 per cent.

—*Gazette de Gynæcologie.*

THE INDUCTION OF ARTIFICIAL LABOR.—In the obstetrical section of the Berlin Congress, M. Calderini (Italy) arrived at the following conclusions:

1. In the interest of the child one should abandon all attempts at the induction of premature labor with a measurement of less than 75 mm. c. b. in a rachitic pelvis.

2. In a narrow pelvis non-rachitic, antiseptic precautions permit of the induction of premature labor up to 85 mm. c. b., and even more in certain cases.

3. The mortality of infants born alive, as a result of the premature artificial delivery, may be diminished by special care.

4. Antiseptic precautions have rendered the induction of premature artificial labor, a great therapeutic resource in many maladies complicating pregnancy.

5. The best methods for inducing artificial delivery are, in narrow pelves, a douche made by an ordinary apparatus through the Fergusson speculum, and the introduction of a bougie up to the fundus of the uterus. In some cases it is convenient to associate puncture of the membranes with the above.

THE VAGINAL SECRETIONS.—M. Doderlein (Leipsic) made some investigations on the vaginal secretions, and found two varieties of the same; the normal secretions are very acid and contain epithelial cells, granular corpuscles, and non-pathogenic bacilli. The other secretions are alkaline or neutral, and contain globules of pus and micro-organisms of different nature and especially the coccus.

In the first case the vagina is not to be feared as an agent of infection during confinement; in the second case, on the contrary, it should be disinfected.

—*La Bulletin Médical.*

TRICHLORACETIC ACID AS AN ASTRINGENT AND CAUSTIC.—Ehrmann has employed this agent in the diseases of the nose and throat. He touches the affected parts with a crystal of the acid, when there is formed a localized white eschar which is rapidly detached. No inflammatory reaction in the vicinity, or unpleasant secondary phenomena. In 140 cases, 87 were cauterized but once, 30 twice, and of the remaining cases 3 to 5 times. Permanent cure in 122 cases. Ehrmann is satisfied that this acid will occupy first rank among caustics in the treatment of diseases of the nose and throat.

Trichloracetic acid may also be used with advantage as an astringent. The following formula is recommended by the author:

℞.—Pure iodine . . . . . 15 grammes.
Iodide of potassium . . . . . 20 "
Trichloracetic acid . . . . . 30 "
Glycerine . . . . . 30 "
Apply locally to the parts with absorbent cotton.

The taste of this solution is not disagreeable; it is followed by a slight burning sensation. The author has employed this solution in one case of follicular tonsillitis (cure after three applications), two cases of ozena (complete failure), fourteen cases of diffuse chronic pharyngitis (eight cures, six notably improved), and thirteen cases of dry pharyngitis (two cures, five marked improvements, four failures, two results unknown).—*La Médicine Moderne.*

TREATMENT OF BURNS.—At the hospital Friedrichshain, of Berlin, there is employed in cases of burns a dry dressing, which, according to Dr. Karl Bardeleben, gives "surprising" results.

The affected part is first carefully washed with carbolized water, two and one-half to three per cent., or else with a three per cent. solution of salicylic acid. The blisters then having been opened, the entire surface is dusted with finely pulverized sub-nitrate of bismuth, after which the parts are covered with absorbent cotton, which is renewed as often as it becomes impregnated with the secretions of the wound.

If the burn is very extensive, we may replace the powdered bismuth with a pomade of the same.

Dr. Bardeleben declares that with this dressing cicatrization is much more rapid, and the pain is more quickly relieved than with all other forms of treatment. And, an observation of importance, notwithstanding the large quantity of bismuth employed, there have never been observed any symptoms of intoxication.

PREPARED COTTON FOR BURNS:

R.—Solution of cocaine (two per cent.)	30	grammes.
Boric acid	2	"
Glycerine	4	"
Carbolic acid	1	"
Absorbent cotton	30	"

Sig.—For the dressing of burns.

—*La Médicine Moderne.*

TRANSLATIONS.

BY W. F. HUTCHINSON, M.D.

DR. GALOGNI, who has studied the subject of *amenorrhœa* for many years, has come to the conclusion that the best method of treatment for the condition is cauterization of the cervix with nitrate of silver. In his hands this remedy has never failed to give satisfactory results.

Nitrate of silver is favorably mentioned in the journals for this derangement by several gynecologists, but not one of them has given it a thorough trial, and he thinks it well worthy the attention of thoughtful practitioners. It works well even in the amenorrhœa of chlorotics.

In an interesting paper, by Professor Cantani, on *Fever and Antipyretics*, he makes the statement that in view of the fact that fever is caused either by diminished irradiation or by increased calorific production, the most rational treatment will be directed, not toward the dispersion of heat, but toward its increased production, and that, of all antipyretics, he considers cold water, freely given, to be the best.

—*La Riforma Medica.*

COLLOQUIAL LATINISTS.—At the close of the late congress, Professor Bacelli, of Rome, made a speech in Latin, speaking in the highest terms of the President, Professor Virchow, to which the learned savant replied in the same tongue, a feat not often attemptde in these days.—*La Riforma Medica.*

REMOVAL OF A PORTION OF LIVER FILLED WITH HYDATID CYSTS BY AN ELASTIC LIGATURE.—M. Terrillon communicates the case of a woman of fifty-three years, who suffered for several years with sharp pains in the right hypochondrium, coming on at certain marked periods. The diagnosis had been a cyst filled with calculi, and an explorative puncture, made in the swelling which existed in the right side, allowed one hundred grammes of hydatid liquid to escape, without diminishing the size of the swelling.

Laparotomy showed that he had to do with a diseased mass, about the size of two fists, composed of a part of liver tissue, occupying the edge of the organ, and totally filled with little hydatid cysts.

A line of demarcation sharply separated the diseased tissue from the rest of the organ, which appeared quite healthy.

An elastic ligature was firmly applied at the point of this line. Almost immediately the ligature seemed to make a pedicle, and the part below the compressing force became turgescent. This was fixed outside the body by a few stitches of suture, and the rest of the wound closed. Iodoform antisepsis.

Little by little, the part of the liver thus pediculated died, without producing any general reaction. After eleven days, as there was a slight elevation of temperature, M. Terillon divided the pedicle. There remained a large wound which cicatrized in thirty days. In fact, the patient was completely cured and regained a normal weight and strength.

This is the first case on record where so large a resection of the liver was followed by cure.

—*La Medicine Moderne.*

A STUDY OF THE THERAPEUTIC ACTION OF THEOBROMINE AND DIURETINE (Mme. Koundjy Pomerantz).—The work of experimental therapeutics, carried on at the laboratory of Cochin Hospital, has recently brought to light a new preparation, called diuretine, which is said to have a more powerful action upon the kidneys in increasing the flow of urine than any substance yet known. It is made by combining one molecule of theobromine, one of hydrated soda, and one of salicylate soda. It is without color, without odor, and easily soluble in water. After a series of studies upon animals, the following conclusions were arrived at:

1. Diuretine, in doses of from three to five grammes, given in one gramme doses every three or four hours, increases largely the urine flow.

2. It attacks directly the renal epithelium; therefore we should not employ it in any case where patients are affected by any considerable organic diseases of the heart.

3. Under the influence of this drug, heart contractions do not change at all, or but very little.

4. It augments rapidly the flow of urine, and the diuresis keeps up three or four times as long as with caffeine.

5. The patient does not readily become accustomed to the medicine.

6. It does not produce difficulty of urination. Passage of water is not accompanied by smarting of urethra, even when the dose is increased to five grammes a day.

7. It has no action upon the central nervous system, and should be administered in milk or chocolate before meals.

8. It produces the best possible effects in cases of dropsy, where diuresis is still possible.

9. When the kidneys are much diseased it has no effect.—*Bulletin General de Therapeutique.*

Medical News and Miscellany.

HOG cholera prevails near Spring Valley, Ohio.

IN France the second of twins born is legally the eldest.

CHOLERA is still prevalent in Tokio and some other parts of Japan.

MEASLES caused 1,033 deaths in Paris during the last twenty weeks.

THERE is a vacancy on the Obstetrical Staff of the Philadelphia Hospital.

THE Chinese are said to endure change of climate better than any other race.

CHICAGO is getting ready for the fair by taking steps to purify her sewerage.

DR. EGBERT H. GRANDIN has removed to 36 East Fifty-eighth street, New York.

SANITATION is so unpopular in Spain that three doctors have been killed by the mob.

PROF. PARVIN and Dr. James Collins returned last week from Europe, on the Rhynland.

DR. N. C. VANDERSLICE, of Phœnixville, a prominent citizen, was killed in the accident last week on the Reading; and Dr. D. F. Solliday, of New Ringgold, had his arm severely injured.

Dr. Lawrence Turnbull is back from Jamestown.

Dr. Horatio C. Wood will soon be back from Europe.

Dr. E. J. Moore is home from a five months' tour of Europe.

By feigning paralysis a man was lately saved from two years' in prison due him.

Pfitzner says that in 36 per cent. of cases examined the little toe had only two phalayes.

Dr. D. H. Coover, of Harrisburg, was in Philadelphia this week. He stopped at the Lafayette.

Prof. William H. Pancoast is back from Europe, and gives an interesting account of his travels.

It is said that India contemplates the formation of a leper colony on an uninhabited island in the Indian ocean.

Dr. Pendergrast, of 3722 Baring street, has returned from a trip through Nothern New Jersey with his horse and buggy.

Dr. A. R. Shaw has entered a civil suit for slander against C. W. Clymer, who had denied Shaw's right to the title of doctor.

Dr. J. B. Mattison writes that there is an error in the statement that tincture of iron colors the urine of an opium habitué blue.

Dr. W. C. Wile, the popular and brilliant editor of the *New England Medical Monthly*, is seriously ill with an affection of the kidneys.

Dr. Horace T. Evans has left an estate valued at $500,000, which he has ordered, in his will, to be divided chiefly among his relatives.

A reception was given by Dr. Benjamin Lee at his residence, 1532 Pine street, last week, to the members of the Orthopedic Association.

We are in receipt of a report from the Chicago Pasteur Institute, of the work done during July and August, which is exceedingly favorable.

Gladstone is said to advocate the free importation of American pork; believing that the danger of disease therefrom is confined to southern climates.

Dr. Wm. M. Angney has brought suit against the city to recover ten thousand dollars, for damages sustained by his property by the bursting of city water pipes.

The supposed leprosy in New Caledonia turns out to be ringworm. We would recommend to the physicians of N. C. a careful perusal of Shoemaker on Skin Diseases.

A new quarterly magazine of philosophy, science, religion and sociology, entitled *The Monist*, will be published in October by the Open Court Publishing Company of Chicago.

A Russian Jew was arrested last week and placed in the Central station, Pittsburgh, on a charge of vagrancy, and upon being examined by physicians was found to be in an advanced stage of leprosy; he is supposed to be the same man who appeared like an apparition in a little Ohio town, threw the place into spasms and then disappeared.

The fund accruing from a legacy to the city by Dr. Benjamin Franklin, which, under the terms of his will, is now available, amounts to the handsome sum of $100,000.

The bark Monrovia arrived in Boston with her crew prostrated with beri beri.

Many men who are not on barks have been prostrated with beery-beery.

Dr. Wetherill has been investigating another lunacy case at Mt. Carmel, Pa., where a family refuses to send an insane member to an asylum, and keep him chained to the floor.

Dr. Mendel, of Berlin, announces that he has discovered that coffee intoxicates. It is barely possible that some man who has been chewing coffee has basely imposed upon the doctor.

Most of the nurses who signed a protest against the admission of Miss Ida Grayson, colored, as a pupil nurse in the Training School for Nurses at the Philadelphia Hospital, have withdrawn their names.

The Boylston Prize, of the Harvard University, for 1890, amounting to two hundred dollars, has been awarded to Dr. H. A. Hare, for an essay entitled: The Uses and Value of Antipyretics in the Treatment of Fever.

Messrs. H. K. Mulford & Co., whose laboratory was destroyed by fire September 5, have removed their laboratory to 2132 Market street, which is especially equipped for their increasing business. It was opened September 15.

The body of a woman named Goeda was exhumed at Szegedin for the purpose of an autopsy. When the coffin was opened it was found that the woman had been buried alive, and that she had given birth to a child in the coffin.

Dr. Nathan F. Mossell, who bears the honorable distinction of being the first colored man to graduate from the University of Pennsylvania, has been acquitted of a charge of criminal malpractice unjustly brought against him.

Seven drops of medicine which Mrs. Richards, of Turtle Creek, bought at a general store, nearly killed her infant. The medicine had been purchased from a Pittsburgh firm, which had pasted paregoric labels on bottles filled with laudanum.—*Record.*

The dispute over the appointment of visiting physicians to the Philadelphia Hospital has again been brought up in the courts; the Mayor holding that as professional experts these gentlemen are not required by law or justice to pass examinations.

Pasteur, the eminent physician of Paris, has been engaged to deliver a course of lectures before the Michigan College of Medicine and Surgery at Detroit the coming winter. A French student of the college will interpret the great man's words to the classes.

Dr. M. M. Moore, a leading physician practising in Wesleyville, was recently married to Dr. Mary Burnham, a physician of the eclectic school. After the wedding the newly-married doctors went to Dr. Moore's home in Wesleyville, and there the doctor, who was a Methodist divine for half a century, officiated at the wedding of his daughter, Miss Belle Moore, to Mr. Edward Chambers Bonnell, a prominent young business man of Cleveland.

A MORNING paper says that Prof. Joseph M. Hirsh, of Chicago, has exhibited to one of its reporters the process by which he is enabled to extract aluminum from clay at a cost of only a few cents per pound, and declares the process is entirely different from any known to the books.

THE actress, Marie Hock, who made her *début* in New York, is dead. Her death was due to a mistake made in a prescription. Her physician ordered a powder for her, which was prepared by a chemist, and either the doctor or the chemist made a blunder. An investigation is proceeding.

DR. MARY FISHER, teacher of drawing in the Girls' Normal School, will soon resign to take charge, as resident physician, of St. Clement's Hospital, at Twentieth and Cherry streets. Dr. Fisher has been connected with the Normal School for over twenty years. She is a graduate of the Women's Medical College.

THE gold medal of the British Medical Association was conferred upon Surgeon Parke of the Emin Pasha Relief Expedition, at the annual meeting of the association on July 21. The recipient was given a most hearty and enthusiastic welcome by the association. Mr. Stanley, who intended to be present, was prevented by illness.

A LARGE number of cases of diphtheria of a very virulent type have broken out in the Frogtown portion of Pittston, and fears are expressed by the physicians that it will become epidemic, There is no board of health there, but the school board and borough authorities are making earnest efforts to stamp the disease out.

DR. WILLIAM PEPPER, who went abroad as a delegate to the International Medical Congress, was to have been much honored as the provost of the University, and preparations were made for his entertainment, but in Antwerp he was seized with a violent attack of influenza and was unable to attend the Congress at all. He is now much improved and will return shortly.

JAPAN, NAGASAKI-KEN, CHOLERA.—The United States consul reports 578 new cases of cholera in Nagasaki-ken, and 306 deaths therefrom, during the period from July 25 to August 3, 1890. From the outbreak of the epidemic until August 3, 1890, there have been officially reported 1,286 cases, and 727 deaths. At the date of the report, August 3, there were 389 cases under treatment.

MESSRS. W. H. SCHIEFFELIN & Co., of New York, are constantly getting up new preparations. Their tablets Sulphonal et Phenacetine, fifteen grains, are composed of a combination of two of their great remedies—Sulphonal-Bayer, ten grains, Phenacetine-Bayer, five grains. Their seven and one-half grain tablets are composed of Sulphonal-Bayer, five grains, and Phenacetine-Bayer, two and a half grains.

KEMMLER'S DEATH PAINLESS.—Dr. George C. Fell related, at a meeting of the American Society of Microscopists, held in Detroit, that Kemmler's blood had been examined with the microscope immediately after his execution, and that it was indicated therefrom that the criminal's death was instantaneous and painless. The blood showed interesting changes. His theory is that death is not due to the lesion of the tissues, but to a shock such as often results from surgical injury.

NEW PATENTS :—

PATENTS GRANTED SEPTEMBER 16, 1890.

Alcohol manufacture	Guignard & Hedouin	Paris, France.
Rectifying and distilling alcohol	E. A. Barbet	Paris, France.
Suspensory bandage	A. Dent	Le Mars, Iowa.
Extract-making apparatus	G. S. Andres	San Francisco, Cal. (two patents.)
Continuous rectification of alcohol, spirits, etc	E. A. Barbet	Paris, France.
Teeth-separator	Ivory & Wayne	Philadelphia, Pa.
Tonic beverage	W. S. Hicks	Ann Arbor, Mich.
Truss	C. E. McCandliss	Atlanta, Ga.
Truss pad	C. S Leonard	Glover, Vt.

TRADE-MARKS REGISTERED SEPTEMBER 16, 1890.

Salve. (The words "Monte Christo," the portrait of William H. Howard, the applicant, and his fac-simile signature)	W. H. Howard	San Antonio, Tex.

LABELS REGISTERED SEPTEMBER 16, 1890.

"Louis M. Boucher's Cholera Cure," and the following eight labels, all registered by Fred. R. Hanrath, Cleveland, O., as titles for Medical Tinctures, viz.: "Euonymus," "Epilobium," "Dioscorea Vil," "Asclepias," "Hamamelis," "Chionanthus," "Digitalis," "Caulophyllum,"	Boucher & Gilbert	Manville, R. I.

PATENTS LAPSED SEPTEMBER 16, 1890.

Medicine-case	M. O. Baldwin	Wamego, Kansas.
Disinfectant-package	W. P. Tenny	Boston, Mass.

PATENTS ISSUED SEPTEMBER 9, 1890.

Dental forceps	B. E. Burger	Merrill, Wis.
Dental vulcanizers	A. H. Stoddard	Boston, Mass.
Substitute for iodoform	Messinger & Vortman	Aix-La-Chappelle, Germany.
Druggist's label-case and attachment for bottles and jars	O. E. Given	Stuart, Ia.
Liniment	W. C. Summers	Forest City, Ark.
Measuring vessel	J. O. Chamberlain	Kirkville, Ia.
Topical remedy (medicine)	Blume & Loving	Walhalla, Tex.

TRADE-MARKS ISSUED SEPTEMBER 9, 1890.

Medicated prune syrups. (The word "German" and the representation of a plum)	C. H. Klauenberg	Carlinville, Ill., and St. Louis, Mo.
Antiseptics and germicides. (The word "Chloro-Phenique" on a ribbon extending horizontally from a disk having heraldic features upon it)	E. T. Jester & Co.	St. Louis, Mo.
Face-bleaching ointment. (The word "Marvelone")	A. H. McDonnald	Albany, N. Y.
Blood-purifiers and alteratives. (The representation of a kicking mule with a rider on his back)	Bill C. Nye Medical and Chemical Syndicate	Bradford, Pa.
Liquid toilet preparations for the hair. (The words "Tropical Spray)	E. S. Couch	Fredonia, N.Y.
Preparation for the cure of catarrh. (The word "Cephaline" inclosed in an equilateral triangle having in each of its angles the capital letter "C")	D. D. Harr	Belmond, Ia.
Suppositories for uterine diseases. (The three words "Compound Clover Blossom," each word being within a link of a chain of intertwined clover blossoms)	Dr. J. Moffatt Medicine Co	Chicago, Ill.

LABEL ISSUED SEPTEMBER 9, 1890.

"Coca-Glycerite Suppositories"	The Goshen Pharmacal Co	Goshen, Ind.

(No patents lapsed on above date.)

CHARLES J. GOOCH, *Patent Attorney.*

LOCK BOX 76, WASHINGTON, D. C.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from August 30, 1890, to September 12, 1890.

Leave of absence for one month, to take effect on or about October 20, 1890, is hereby granted First Lieutenant Leonard Wood, Assistant Surgeon, with permission to apply for an extension of one month. S. O 74, par. 1, Department of California, San Francisco, Cal., August 30, 1890.

Leave of absence for one month, to take effect September 15, 1890, is granted First Lieutenant Theodore F. De Witt, Assistant-Surgeon. S. O. 76, Headquarters, Department of Texas, San Antonio, Texas, Sept. 1, 1890.

APPOINTMENT.

BAXTER, COLONEL JEDEDIAH H., Chief Medical Purveyor. To be Surgeon-General, with the rank of Brigadier-General, August 16, 1890, *vice* Moore, retired from active service. Headquarters of the Army, A. G. O., Washington, September 1, 1890.

Leave of absence for one month, on surgeon's certificate of disability, is granted Major A. A. Woodhull, Surgeon, with permission to go beyond the limits of the department. Par. 1, S. O. 122, Department of the Missouri, September 5, 1890.

By direction of the Acting Secretary of War, First Lieutenant Nathan S. Jarvis, Assistant-Surgeon, is relieved from duty at Fort Verde, Arizona Territory, and will report in person to the commanding officer, San Carlos, Arizona Territory, for duty at that station. S. O. 208, par 2, A. G. O., Washington, D. C., September 5, 1890.

Leave of absence for one month is granted Captain Edward C. Carter, Assistant-Surgeon. Par. 2, S. O. 108, Headquarters Department of the Columbia, September 6, 1890.

By direction of the Acting Secretary of War, the following changes in the stations and duties of officers of the Medical Department are ordered: Major Charles L. Heizmann, Surgeon, is relieved from duty at San Antonio, Texas, and will report in person to the commanding officer at Fort Clark, Texas, for duty at that station, to relieve Captain Edward B. Moseley, Assistant-Surgeon, who, upon being relieved by Major Heizmann, will report in person to the commanding officer at San Antonio, Texas, for duty at that station. S. O. 211, par. 23, A. G. O., Washington, D. C., September 9, 1890.

By direction of the Acting Secretary of War, Major Joseph K. Corson, Surgeon, is relieved from duty at Fort Sherman, Idaho, and will report in person to the commanding officer, Washington Barracks, District of Columbia, for duty at that station. S. O. 212, par. 4, A. G. O., September 10, 1890.

By direction of the Acting Secretary of War, a board of medical officers, to consist of Colonel Edward P. Vollum, Surgeon, Major George M. Sternberg, Surgeon, Major Albert Hartsuff, Surgeon, Captain William E. Hopkins, Assistant-Surgeon, is appointed to meet in New York City, on October 15, 1890, or as soon thereafter as practicable, for the examination of candidates for admission into the medical corps of the army. S. O. 213, par. 8, A. G. O., Washington, D. C., September 11, 1890.

By direction of the Acting Secretary of War, leave of absence for three months, commencing about October 1, 1890, is granted Captain Frank J. Ives, Assistant-Surgeon, provided one of the Acting Assistant Surgeons serving in the Department of the Missouri can be assigned to duty in his stead at Fort Sill, Oklahoma Territory, during that time. Par. 26, S. O. 213, A. G. O., Washington, D. C., September 11, 1890.

By direction of the Acting Secretary of War, Captain John J. Cochran, Assistant-Surgeon, now on duty at Fort Adams, Rhode Island, will proceed to Mount Vernon Barracks, Ala., and report in person to the commanding officer at that post for temporary duty, and, on completion of the duty contemplated, he will return to his proper station. S. O. 214, par. 2, A. G. O., Washington, D. C., September 12, 1890.

By direction of the Acting Secretary of War, the leave of absence for seven days heretofore granted Major Henry McElderry, Surgeon, by the Superintendent of the U. S. Military Academy, is extended to November 10, 1890, on account of sickness. S. O. 214, par. 5, A. G. O., Washington, D. C., September 12, 1890.

By direction of the Acting Secretary of War, leave of absence granted First Lieutenant William N. Suter, Assistant-Surgeon, in Special Orders No. 149, June 26, 1890, from this office, is extended fourteen days. S. O. 214, par. 6, A. G. O., Washington, D. C., September 12, 1890.

PHYSICIANS' FAVORITE PHAETON,

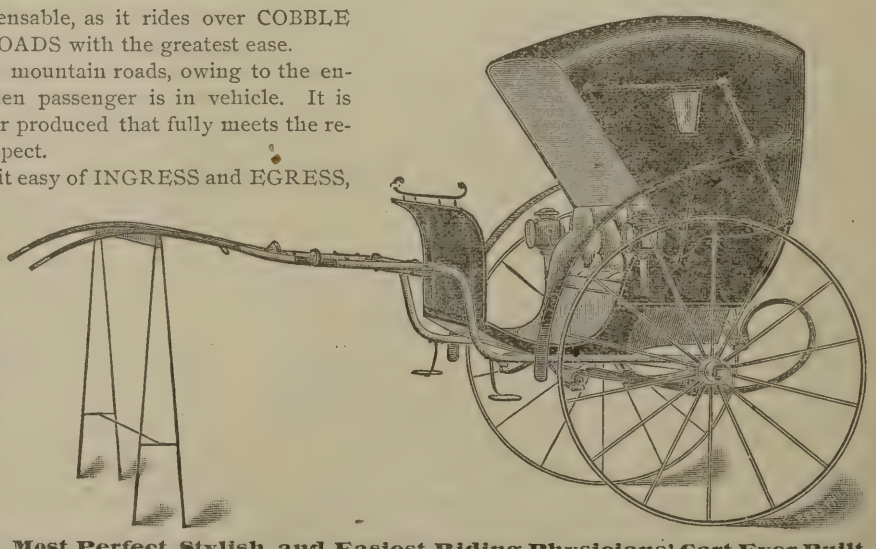
Guaranteed to be Absolutely Free from Horse Motion or Weight on Animal.

THE CHADWICK TWO WHEELER.

For Physicians' use it is indispensable, as it rides over COBBLE PAVEMENTS or FROZEN RUT ROADS with the greatest ease.

It is especially adapted to hilly or mountain roads, owing to the entire absence of weight on animal when passenger is in vehicle. It is entirely new and the only vehicle ever produced that fully meets the requirements of a physician in every respect.

The low hang of the body renders it easy of INGRESS and EGRESS, thus overcoming one of the most monotonous parts of the physicians' practice. In the upholstery of the seat and back, it affords the greatest luxury. Has regular Physician's Close Top, with large side lights, stationary storm apron on dash, large drawer under seat for instruments or medicine case, and is furnished with large serviceable French Cylinder, oil burning reflector lamps when desired.



Most Perfect, Stylish, and Easiest Riding Physicians' Cart Ever Built.

Built with pole for team, instead of shafts when desired, as in the absence of weight on animal, it is the only two wheeler to which a pole can be successfully used. Making it of greater ease and of lighter draught for animal to handle, than any two or four wheeled vehicle ever produced.

Send for Illustrated Catalogue and Price List. Correspondence Solicited.

THE EPIDEMICS OF DIPHTHERIA, SCARLET FEVER AND LA GRIPPE AT THE OHIO SOLDIERS' AND SAILORS' ORPHANS HOME, XENIA.[1]

BY C. M. GALLOWAY, M.D.,
Physician at the Ohio Soldiers' and Sailors' Orphans Home.

A HISTORY of the late epidemics at the Ohio Soldiers' and Sailors' Orphans Home, at Xenia, Ohio, will be better comprehended in the light of a brief history of the founding and growth of this noble institution, so little of which is known to the medical profession of our State and to the public at large. This home for soldiers' and sailors' orphans had its birth in the year 1869, in the councils of the Grand Army of the Republic (foremost of which was Forsyth Post, of Toledo, Ohio), and in the hearts of the philanthropic citizens of Xenia and Greene county, fired by the burning eloquence of Chaplain G. W. Collier, now Past Chaplain-in-Chief of the G. A. R., and Rev. P. C. Prugh, then pastor of the Reformed Church of Xenia.

On June 31, 1869, at a meeting of citizens of Xenia, the assembly, catching the spirit of the comrades of the G. A. R., then and there contributed the sum of $16,500 for this worthy object.

In the meantime the citizens of Xenia and the representatives of the G. A. R. were actively and harmoniously at work. The press, all over the State, favored the project, and advocated the erection of suitable buidings at once.

The sum grew to $30,000, and real estate was purchased one mile southeast of Xenia—a free-will offering of our patriotic citizens—toward erecting a permanent home for the children of the heroes, who had fought and fallen in defense of their country.

"To the Grand Army of the Republic in Ohio, to the generosity of the patriotic citizens of Xenia and Greene county, and to the State at large, is awarded the honor of establishing and maintaining one of the noblest institutions known to the civilized world—The Ohio Soldiers' and Sailors' Orphans Home."

In the year 1870, seventy-one children were gathered at Xenia and supported by the private subscriptions of her citizens, and when a few months later the first executive committee met in Xenia, they found one hundred children in their temporary quarters, and applications pending for many more.

By act of legislature the Ohio Soldiers' and Sailors' Orphans Home became a State institution April 4, 1870, and at that time embraced one hundred acres of land and buildings accommodating two hundred and fifty children. Generous yearly appropriations from the State, intelligently expended by a board of trustees, has enlarged it, until now it has become a great educational and training home, in the broadest sense of the term, accommodating almost 1,000 children, with one hundred and thirty-five adults engaged in their care and training.

"It embraces two hundred and ninety-three and twenty-three one-hundredths acres of land and forty-eight buildings, composed of an administrative building three stories high, with large dining-room attached, twenty-eight two-story cottages, two three-story school houses, chapel, hospital, laundry, industrial building, engine rooms, gas-house, greenhouses, and all the necessary farm buildings."

Great as is the capacity of this Home, requiring a yearly appropriation of almost $200,000 for its maintenance, there are to-day almost 1,000 applications on file awaiting admission, for "all limitations as to the death, or cause of death, of the father, have been removed, and any child whose father served in the army or navy, and is now in indigent circumstances,

[1] Read before the Ohio State Medical Society, Columbus, O., June 6, 1890.

is entitled to admission." Children are taken in as young as two years of age, and are discharged, boys at sixteen, and girls at eighteen years of age. These facts are compiled largely from Hill's History of Greene county.

As to the former sanitary condition of the Home, the statistics show that from October, 1871, to October, 1889, there were thirty-nine deaths from various causes, two of these being accidental.

From October 4, 1889, to March 16, 1890, there were thirty-eight deaths among the children; of this number two died of scarlet fever, one from an overdose of aconite mixture, taken while in delirium, during an attack of la grippe, and one from a complication of pulmonary and cardiac trouble.

A healthier natural location, for a children's home, could scarcely be found within the boundaries of our State, for, since the founding of the institution, a period of nineteen years, seventy-four deaths have occurred among the 4,220 children admitted, three of his number being accidental. Ever since the yeart 1886, diphtheria has been present in Xenia—it is there now—resisting the united efforts of physicians and health-boards at extermination. On the 29th of September, 1889, this disease made its appearance at the Home. Two boys in cottage No. 18 were attacked, one dying October 3, and the other October 7. These were the only cases occurring in that cottage. From this beginning the disease continued with more or less virulence, until April 15, 1890, when it ceased. During this time two hundred and fourteen cases among the children and twenty cases among the employés came under the observation of the physicians of the Home—in all, two hundred and thirty-four cases, with thirty-five deaths—a mortality rate of about 15 per cent. About one in ten of these cases presented, during convalescence, the usual sequelæ. A few suffered from relapse.

Scarlet fever, in a mild form, made its appearance about the middle of October. A little girl was attacked while absent on her vacation, and returned to the Home during the period of desquamation. The case was not discovered by matron or physician until others were attacked, and before this disease abated two hundred and forty cases came under our care. Two deaths, one complicated with cardiac trouble, occurred from this disease, and as sequelæ, three cases of acute nephritis, easily handled.

The almost entire absence of kidney complication in such a great number of cases was due, it is believed, to the fact that butter-milk was daily given in generous quantity to those able to bear it, from the day they were brought into the hospital until they were well. This disease, combined with diphtheria, made a serious and often fatal complication, from which a small proportion only of those thus attacked made recovery. Scarlet fever disappeared entirely from the Home about January 10, 1890.

La grippe made its appearance about the middle of January. This peculiar disease swept through the institution attacking about every child and employé. Over three hundred children were attacked and confined to their beds in their cottages from four to eight days, and at least one hundred more were confined to their dormitories for a few days, not being sick enough to be put to bed. The care and nursing of this great number of sick children devolved upon the matrons of the cottages, in addition to their usual daily duties, for the reason that all the hospital and convalescent wards, twenty in number, were filled with children sick and convalescing from diphtheria and scarlet fever complications. Besides, we found, from sad experience, that a la grippe throat was a more fertile field for the engrafting of diphtheria than was a scarlet fever throat—every child dying that came into the hospital with this complication.

Too much credit cannot be given to the teachers of the Home schools (formed by direction of the trustees into a corps of nurses for convalescing wards) for their constant and faithful services. When the schools were closed these ladies were given option of a vacation until the epidemics abated, or enroll themselves as nurses. Without exception, they volunteered to care for the sick children, and remained faithful to the trust reposed in them, although a number of them contracted diphtheria.

The matrons of the cottages are to be commended highly, in that they all remained among their children, caring for the well ones, nursing the sick ones, and, when necessary, enduring the privations of quarantine with their children for weeks and months cheerfully, and without a murmur, faithfully carrying out the following order, issued from the medical department at the beginning of the epidemics:

"Examine, carefully, every child's throat morning and evening, using the handle of a teaspoon to depress the tongue.

"Examine, carefully, every child's body, once daily, for eruptions, redness of skin, or scales.

"Children having redness of throat, or ulceration of tonsils, should be kept in their cottages until seen by the physician.

"Children having headache, chill, or loss of appetite, should be reported to the physician at earliest moment.

"Children complaining, should not be sent to school, neither detailed for work, until seen by the physician."

The faithful execution of the above order entailed upon the matrons, daily, an endless amount of care and toil, and ceaseless vigilance and attention accompanied this work. The following, from the Cincinnati *Commercial Gazette*, faithfully portrays a condition daily met by the physicians: "One of the greatest stumbling-block in the way of the physicians is the dread and fear of the disease and the hospital existing in the minds of the children, who, though probably suffering already with the disease, would deny that they were in any way ailing, and would endeavor to deceive their matrons and the physician in this respect, although always truthful and obedient." The ever-watchful eyes of the matron were, however, quick to detect disease, and contagious cases were immediately removed from the cottages.

Employés, as a rule, remained, and discharged duties assigned them, which, at times, were truly arduous.

The attachment and devotion of those in authority, of teachers, matrons, and employés, for the children, was truly wonderful. Parents will stay by the bedside of their children, sick and dying of contagious and loathsome diseases, with a devotion that death alone will quench. The world expects, and demands, parental and filial affection and care at all times, and especially in sickness and danger; yet, outside of the home-circle, as we all know, contagious and infectious diseases are shunned by all. I believe the pages of history may be searched in vain for another instance where the officers and employés of a State institution, surrounded for months by pestilence and death, unflinchingly stood at their posts, and heroically did their entire duty, when

hands and hearts grew tired and weary awaiting the day of deliverence, long delayed in its coming.

The following will illustrate the spirit of devotion that prevailed; Major Noah Thomas and his worthy wife, the superintendent and matron of the Home, at the outbreak of the diphtheria, were strongly advised by friends to remove their children, four in number, away from the Home to a place of safety. With that heroism that always inspires the true soldier, he replied: "My children are no better, and their lives are no more precious to me, than those of the nine hundred children of my dead comrades under my care. My children will stay here with me, at this Home, and take their chances with others;" and they did stay, although one of them was stricken with the dread disease, and he, also, was attacked.

Eight cases of pneumonia developed from la grippe; none of these proved fatal. A fatal case of phthisis pulmonalis brings us to the 15th of April, 1890, when our last case was pronounced convalescent; the closed schools and industries were opened, and teachers and pupils once more resumed their accustomed duties.

A complete history of these epidemics, with their daily toil and burdens of cares, anxieties, perplexities, hopes, fears, sickness, pain, sorrows, and deaths, can never be written. Daily contact was necessary to fully comprehend it.

October 10, 1889, found us in quarantine, and almost completely isolated from the outside world, with nine hundred and thirteen children enrolled and present in the cottages, eight hundred and fifty-four of these attending the schools daily.

These were dismissed by order of the Board of Trustees, and six large school-rooms fitted up and used as convalescing wards under the immediate supervision of Maj. G. M. Patterson, the efficient military instructor of the Home, who gave us valuable assistance.

The work becoming too great for one physician, the trustees, on October 27, secured the services of Dr. S. S. Wilson, of Xenia, who devoted the greater portion of his time to the care of the sick children until March 15, when, his services being no longer needed, he voluntarily retired from the work. His constant and devoted services were cheerfully given —to the great detriment of his private practice—and too high commendation cannot be awarded him for his self-sacrificing labor.

The State Board of Health took cognizance of our condition, in the person of its secretary, Dr. C. O. Probst. The defects of the heating arrangements, plumbing, ventilation, and sewerage were pointed out to him, and, after thoroughly inspecting our hospital, which he designated "a death trap," and approving our system of treatment, quarantine, and fumigation, he gave us the unwelcome assurance that we would not be free from diphtheria during the entire winter.

As our little hospital rapidly filled with sick, the trustees gave us three large rooms in the industrial building, and a double cottage with four large rooms, which, with those at the school building, made twenty wards for the sick and convalescing children of diphtheria and scarlet fever alone—the children sick from la grippe being kept in the cottages.

The past winter, as all will remember, was remarkable for the great number of wet and rainy days. Damp weather, we found, greatly increased our mortality rate and the number of new cases demanding treatment. Every cottage from which a case of diphtheria was taken was immediately quarantined, and the inmates fed by a detail of employés. In this manner eight of the twenty-eight cottages were put under strict quarantine two or more weeks, or until entirely free from disease. The inmates were then sent to convalescent wards in the industrial building, where they remained two weeks with their matrons; the cottages were thoroughly cleaned, painted, and whitewashed, all clothing and bedding fumigated and sent to the laundry to be washed in a strong solution of corrosive sublimate. The books, woolen wraps, pillows, tapestry, and carpets were subjected first to fumigation from burning sulphur—fifty pounds to each cottage—for seventy-two hours, and afterward to a dry heat of 275° for ten hours. This renovating process required about two weeks for each infected cottage, after which the inmates were returned. Notwithstanding all these efforts, two cottages, Nos. 1 and 4, had to be temporarily abandoned. Three times we took the children out of these two cottages, cleaned, fumigated, painted, and whitewashed the dormitories and living-rooms; washed, thoroughly, all clothing, beds, and bed clothing, and returned the inmates, and as often removed fatal cases of diphtheria, until we had taken out four from one and five from the other.

At one time Governor Foraker sent a committee, composed of Drs. A. G. Byers, of Columbus, and Jas. L. Wilson, of Greenfield, members of the State Board of Charities, bearing to us words of cheer, and, in his characteristic manner, said to us: "Buy, *at once*, everything that is needed for your sick children. The great State of Ohio will see that all the bills are paid."

This committee spent an entire day with the sick and convalescing children, and gave us valuable suggestions.

In February, Governor Campbell and the General Assembly of Ohio appointed a committee, composed of Drs. C. O. Probst and F. C. Hoover, of Columbus, and Prof. E. T. Nelson, of Delaware, members of the State Board of Health, to investigate the sanitary condition of the Home. The committee spent about three days with us. At their suggestion, the floors of the two infected cottages, 1 and 4, together with the plumbing, were taken out and replaced by new. The cottages were then put in order, and the children returned. No new cases have occurred in these buildings since. This committee also favored us with valuable suggestions.

Thus the weary days sped along, each day bringing new cases into the hospital, and sending into the quarantine wards others, who, properly bathed, disinfected and clothed, had passed through the crisis and were convalescing.

The following were the methods of quarantine: From the hospital the children were sent to the wards in the industrial building, and put in charge of nurses, where they remained two weeks. If no new cases developed, from there to the wards in the school building, where they stayed two weeks longer, when, if there were no new developments, they were sent to their cottages and kept under observation one week longer. They were then allowed to go to the dining-room and mingle with the children. Any child suffering from relapse was sent back to the hospital and passed through the wards again.

The continuance of these diseases, through so many months, very naturally aroused great anxiety among the parents and friends of the children all over the State. This anxiety was intensified an hundredfold by false and sensational individual reports and the

wild rumors printed in a few of the newspapers of the State. The *Cincinnati Enquirer* sent a special reporter to the Home to obtain the facts, and in its issue of November 25, 1889, is found an accurate newspaper account of our condition at that time. *The Xenia Gazette and Republican*, the *Newark Daily American* and the *Home Weekly* presented, from time to time, accurate reports, and did much to allay the fears of those whose loved ones were almost entirely cut off from communication with the great outside world and its sympathy.

In the month of January, Superintendent Thomas, enfeebled by an attack of la grippe, contracted diphtheria, and for six weeks his life was despaired of.

Mrs. Hardesty, the matron of the hospital, worn out with constant care and attention, suffered from a severe attack, of four weeks' duration, and at different times all our nurses contracted the disease. At one time nurses could not be obtained at any price, and a brave girl, eighteen years old, with a noble, Christian heart, volunteered to help us. After a few weeks' work, she was stricken down, and died in four days. Her brother, Wilber, aged sixteen years, came to her dying bedside, under protest of the physicians, and in a week afterward he died. Her mother, also, had a light attack.

We buried this brave girl in our beautiful little Home cemetery, among those she loved so well, and whose call for help she answered with life.

Among the recommendations made by the committee of investigation appointed by Governor Campbell and the legislature, were the following:

"A new hospital for general diseases should be built at once. It should not have less than one hundred and fifty beds, and be constructed on modern plans. The present hospital should be remodeled, by dividing the larger wards and providing a separate entrance to each, and used as a quarantine building. The heating of each ward should be properly regulated, and provision made for increasing the ventilation of each ward."

In searching for a cause for the diseases prevailing at the Home during the past winter, we have not far to go. Scarlet fever was brought to us by one of the children. La grippe was almost universal throughout our State, and we did not hope to escape its presence. As to diphtheria, it has prevailed in Xenia for the past four years; it was prevailing in our city last winter, and is present there now. A number of the employés live in Xenia, going to the Home every morning and returning at evening; besides, visitors daily go to and fro, not only from Xenia, but from different parts of the State. Under these conditions, intelligent minds were not surprised when diphtheria appeared among the children; indeed, it was a marvel it had not reached the Home sooner.

The cause for its continuance was not to be found in the overcrowded condition of the cottages, for they have always contained from thirty-two to thirty-six children, each. It was not due to the amount or kind of heat, or the method of ventilation of the cottages, for these have been the same for many years. Neither was it the fault of the plumbing or sewerage, for careful examination revealed little or no defect in either, although both were of old style and pattern. The drinking-water was from the same source as for the past nineteen years, and was not the cause of the disease from which we suffered.

The continuance of diphtheria is to be found in the fact, that hospital accommodations for two hundred and fifty children were, by our legislature, deemed as sufficient for nine hundred and fifty. Time and again had our lawmakers turned a deaf ear to our urgent calls for a more commodious hospital.

The little "death trap" building, with its seven small wards and fifty-two single beds, was all we had when the epidemics burst upon us with the force of a tornado. Had we had hospital accommodations in proportion to the number of children enrolled at the Home, I am prepared to make the statement that the epidemic of diphtheria could have been more easily and more quickly handled.

DRUNKENNESS—WHAT IS IT?

By T. L. WRIGHT, M.D.,
BELLEFONTAINE, O.

"Alcohol yields the simplest instance in illustration of the disturbing action on mind, of a foreign matter introduced into the blood from without; . . here we have the abstract and brief chronicle of the history of insanity."—*Maudsley.*

I speak of drunkenness from alcohol exclusively. Forms of intoxication from other sources have specific characteristics peculiar to themselves; besides, some of the most obnoxious and disabling qualities of drunkenness from alcohol are wholly absent in the inebriation that arises from the use of other toxic agents. Inferences of a conclusive character respecting these declarations will abundantly appear in the discussion of the nature of purely alcoholic drunkenness; so that special efforts to distinguish between the effects of opium, chloral, etc., on the one hand, and the effects of alcohol on the other, are not here necessary.

1. If insanity is an aberration of mind consequent upon the operation of a cause that is beyond the volitional control of an individual, then any one who is drunk from alcohol is, while the drunkenness continues, truly and absolutely insane.

The law not only admits this, but it insists upon it. The law actually draws from this fact—the uncontrollability of the mind in drunkenness—an inference, or *dictum*, that declares that "drunkenness is no defense for crime." This has the appearance of a most singular "quirk" it is true; especially when it is remembered the law also is positive in its assertion that "where there is insanity there can be no crime."[1]

But the legal conclusion is reached by a process of reasoning. It involves an assumption that is incorrect in point of fact—at least in a vast number of instances. The law claims in other words that the drunken man is a "voluntary madman"—a seeming contradiction in terms; something beyond human nature—as though a mind could, *being in a sound condition*, use its volition to destroy its volition. The great executive department of mind known as *will* can hardly be supposed, while operating in conjunction with a calm judgment and a healthy consciousness, to deliberately enact the rôle of *felo de se*. It surely is a very questionable assumption, to say the least, that a mind being sane, ever voluntarily places itself in a condition in which *it knows* (before hand) that it cannot control itself.

It is doubtful if the sound mind can conceive itself to be truly and sensitively unsound. The drunkard does not believe that he cannot control himself when intoxicated; albeit he truly cannot. Now, indeed, can any one, judging from drunken actions in others, conclude that in himself, similar exposures will of necessity occur, should he become drunken.

The feeling of the true and impregnable *ego* cannot be made to give place at will, to the intrusion of a morbid, a feeble and wavering personality.

[1] Med. Jurisp. of Inebriety, p. 129.

When alcohol is taken to fortify the criminal intent in the commission of offences, it does not act by directly strengthening a fierce and truculent nature. Alcohol never strengthens; never brightens anything or any faculty; it always tears down. It weakens, directly, all the powers of the mind. But it does not do this work *equally;* and thus it happens that, while the purpose, or will, in the commission of crime is *abstractly* diminished by drunkenness, still it may be *relatively* increased. What is the distinction between an abstract and a relative increment of the criminal purpose when the result is the same? When, in either case, the onset to crime is precipitated? There is this great difference; false reasoning, or reasoning from false premises, in such important matters of crime and punishment may readily be applied to interests where an indifference to the result may not exist, and where, therefore, harm and injustice may be done.

The simple explanation of the manner in which alcohol fortifies (relatively) the criminal purpose is this: The grosser faculties and the animal propensities of the physical man are more fundamental and immovable than the finer sensibilities of his moral nature. Hence, while the nervous inhibitory phenomena, which alcohol always produces, may exert very little effect upon the brutish instincts of the mere animal, they may seriously depress and deaden the moral feelings and sentiments. Thus criminality becomes practically relieved of all obstruction, all temporizing, all protest. Dr. T. S. Clouston, of Edinburgh, in a recent paper says: "It is now pretty generally recognized that as the moral faculties were the last to be evolved, they are commonly the first in brain disease to disappear." Again, Dr. C. says: "It should never be forgotten that alcohol poisons, as well as exhilerates. It affects more strongly the highest brain functions of emotion and control."[1]

The formula of the law is this: "He who while sane puts himself voluntarily into a condition in which he knows he cannot control his actions, must take the consequences of his acts; and his intentions may be inferred."[2] I have briefly discussed these propositions elsewhere and will not, therefore, dwell upon them here.[3] But one great fact is certain, and beyond dispute or cavil: the law is correct when it assumes that a man drunken from alcohol cannot control his actions.

2. The disastrous effects of alcohol upon the human constitution may be viewed from an almost infinite variety of points of observation, for these effects are universal. Alcohol assails every element of human character, and every organ and tissue of the human structure. The moment alcohol begins to operate upon sensibility a material change is observed in the personal aspect and demeanor. The eye, for instance, is brightened, and the movements are alert and restless. The countenance is at first half smiling, with an arch look. These appearances may change, and, indeed, they do change in the most radical and astounding manner, as drinking continues and the period of drunkenness is prolonged. It is important to know, however, that neither the appearance of a drunken man, nor his movements ever represent a sound and rational mind.

What is the cause of this brightness of the eye, this cunning and waggish look, and these airy movements of early drinking? Is alcohol really a mind stimulant, and has it aroused and intensified the intellectual vigor? Has it imparted to the mind augmented strength, and scope, and brilliancy? When men drink to exalt the mental character, to enlarge the mental horizon, to give steadiness and nerve to mental exposition, are they wise?

The depressing influence which alcohol exerts upon nervous sensibility every where—by virture of its anæsthetic properties—is well-known and universally recognized. It is not essential to the present discussion that the injuries inflicted by alcohol upon nutrition, oxydation, and upon the topic integrity of the organism, should be considered. It is sufficient to say that alcohol is sure to debase and weaken sensibility in every department of the nervous system. This, of course, applies to the bad impression of alcohol upon common sensation, as well as upon the perfection of the several senses. It is a fact that the acuteness of all the senses is not only dulled by alcohol, but their completeness is otherwise seriously impaired. The hallucinations and illusions of drunkenness are standing subjects for the gibes and small wit of carless minds.

As sensation is, so ordinarily will perception be. If things are presented to the mind in a dim and incomplete form, the mental pictures corresponding will be dim and misleading. If perceptions are received as through a haze or fog, the related ideas in the mind will partake of the character of such perceptions. If the objects of the exterior world are pictured upon the mind through sensation and perception in unnatural and distorted proportions, they cannot be conceived of in their right and natural aspects. They will appear like huge and curious phantasms, imposing false beliefs upon the intelligence, and leading to unnatural and irrelevant thoughts and speech and conduct.

Now alcohol, through the distorting operation of a nervous system poisoned by it, addresses the mind through the senses in the very way herein described. A perception is perhaps presented that is a caricature of nature. The co-operation of the several senses, also impaired and likewise testifying wrongly, confirms the mind in erroneous conceptions. The ludicrous pictures of the drunken imagination provoke mirth; the phantoms excite surprise; the imperfection and haziness of sensation exaggerate the ideas beyond what is reasonable and true; while a comparison of the alcoholic concepts with allied images in memory excites the most grotesque mental apparitions, and begets no end of silly conceits and drunken nonsense. The newly drunken man is at one and the same time in a condition of unbounded amusement and astonishment. He is in a new, though unreal and fantastic, world; and he shows this fact in his language, his movements, and his conduct. And all this is the sum and the nature of the "brilliancy" with which alcohol invests the minds of those who partake of it. Will it be claimed that these things imply a true and substantial increase in intellectual power and mental activity?

Knowledge acquired in drunkenness is of necessity imperfect, distorted, inflated; the drunken man perceives all things in false lights. He cannot be a truthful witness. His moral nature is inhibited and he don't care for truth; while his intellectual capacity is so deteriorated by the toxic power of alcohol that he is incapable of perceiving truth.

Language is of course a reflection of the mental condition. The drunkard, in his speech, is full of absurdities and extravagance, because his conceptions are incongruous and incoherent. He speaks

[1] Quar. Journal of Inebriety, July, 1890, pp. 229–232.
[2] Med. Jurisp. of Inebriety, p. 7.
[3] Journal of Am. Med. Association, March 8, 1890.

perchance the language of exaggeration; for his ideas are stilted and grown out of rational bounds through the deceptions inseparable from an indistinct and hazy sensibility. If he becomes sententious and tries philosophy, his expressions are simply inflated bubbles which the point of a little analysis and criticism will quickly expose and explode. Should he essay the rôle of orator, his mouthings and high-sounding periods will, upon examination, prove to be pure and absolute emptiness. His pretentious efforts clothe no useful thoughts, and represent no sublime emotions. The drunken mind is an incompetent mind; yet it has ruled nations, spoken with authority and impudence, made war, fought battles; but always, beyond a reasonable doubt, to the detriment of mankind and the substantial injury of the human race. Alcohol, like a robber and ruffian, habitually overcomes the modesty of true merit. This is the sum total of drunkenness with respect to its mental *status*. Its literature, its legislation, its statesmanship, its oratory—all that it is or has been, or can be—are shams.

All this does not look as though alcohol could ever be useful in strengthening the mind. In truth, drunkenness is itself helpless. It is a condition beyond the sphere of will; for it is inaugurated and maintained by physical causes over which mind can have no authority. The drunken man always believes in *himself*. To his mind there is no such thing as doubt. The man with an insane delusion has the same characteristic. Every morbid belief has to him the force of demonstration; anything contrary to it being inconceivable to his mind. Sane people doubt, not drunkards or lunatics.

Thus, unmanageable mental incompetency is ever present in the drunken state; and it varies in degree as the intoxication is more or less profound—it being understood, of course; that consciousness is not extinct.

3. The mental aberration of drunkenness, however, is not dependent exclusively upon faults of nervous sensibility and the direct deterioration of nervous function. True, the impairment of the senses, both with respect to completeness and accuracy, is in itself sufficient to cause serious disturbances in thought and conduct. But in drunkenness, to the defects of mere sensation and perception already noted, there should be added, instability of movement, and inco-ordination of function amongst the several great departments of the human organism. If the misinformation and the false beliefs, dependent upon imperfection of the perceptive faculties, deceive the judgment and lead the mind astray, how much more do false beliefs conduce to mental disorganization, when they are themselves misapplied, through an imperfect interaction of the motor, and rational and moral powers? To accomplish the behests of individuality, to complete the impersonation of self, there must be symmetry of function—unity of purpose—both in regard to time and in regard to events, between these three component elements of human nature: namely, movement, reason and motive; or, as commonly written, body, mind and soul.

When intoxication is present, and the power of alcohol is in authority, there is an absence of normal co-ordination in the functions of these three great elements of human character. The mind and hand, for example, do not readily respond to the calls for each other. The dormant sensibilities fail ofttimes, to notify the intellect of the necessity of its co-operation with motor or muscular activity. The torpid and lifeless touch will, perhaps, press with unconscious force upon the trigger, and, incapable of alarming the rational faculties, or of receiving alarm from them of impending danger, the weapon is unexpectedly discharged, and possibly a tragedy is enacted.

The inhibitory power exerted by alcohol over the finer sensibilities is very likely to withdraw the supervision of the moral nature over conduct. The animal propensities are left to their own courses, unrestrained by their natural monitor. A noted criminal case in St. Louis is an example of this. A young man, accustomed to borrow jewelry from his grandmother to pawn for means to buy liquor, on one occasion, when deeply intoxicated, placed his hands upon her person and abstracted her watch and drew the rings from her fingers. It was after night. The woman had retired, and in the bewilderment of sudden awakening, she probably struggled and resisted. She was aged and feeble, and suffered greatly from asthma. She died under this treatment, and the drunkard was horrified the next day when arrested and informed of the facts. The old lady and her grandson were the greatest of friends, she being his kind refuge and protector when he was in trouble.

While the moral sense of this man was probably latent, there is no likelihood that the act was prompted or attended by any criminal motive. The component elements of the human nature in this person were distracted in their co-operative functions. There was absence of symmetrical activity among the mental, moral and motor capacities. The motor system was no doubt morbidly impressed by the anæsthetic properties of the poison, and the muscular force employed was in consequence greater than was supposed or intended. The mind was deprived of the power to rightly measure the strength of the hand's grasp. The sense of feeling was destroyed. In this case there were two defects in the co-ordination of function among the essential constitutional powers. One arose from latency in the sense of muscular force, the other from abatement or absence of the moral sensibilities.

When circumstances do not point to criminal intent, such events as this are apt to be classed as "accidents." In truth, they are not accidents, but the inevitable consequences of mental impairment, dependent upon the toxic properties of alcohol. The mental powers are depressed as well as deranged. No mind can foresee the consequence of the so-called accidents of alcoholic inco-ordination, and no mental power can prevent them.

There is a peculiar state of mind called *trance*, that is not unusual in drunkenness. It may come on with moderate drinking; it is more common, however, after deep potations. It is a condition not necessarily consequent upon alcoholic indulgence, although alcohol is a very effective cause of its appearance in certain constitutions. In alcoholic trance, consciousness at best is but partially influenced by the material surroundings. It is, in a great degree, associated with subjective, or automatic life—the things of the life of common relation being unknown to memory when the trance state has passed away. Here is a mental situation wherein the fitness of things, as apparent to ordinary observation, is not clearly noted. It may be supposed, without violence to probability, that the faint glimmerings of common sensibility and life, mingling with the suggestions of a co-temporaneous automatic existence, would arouse strange incentives and evolve unconscious motives, greatly at variance with those of ordinary rational experience.

It is certain that crimes, inexplicable in atrocity and motive, are not infrequently perpetrated by drunkards during the trance state. The actual in-

citements to crime and murder that are associated with this singular condition of the mind cannot, probably, ever be known. For, upon "awakening"—that is, when consciousness again becomes normal, little, and sometimes no, remembrance of its trance experience is retained. It is highly probable, however, that both—imperfection in the perceptive faculties, and inco-ordination in the mutual interaction of the predominant departments of the human organism—unite in producing dangerous and unnatural causes of thought. Here, there is no normal consciousness, no rational intent, no responsibility.

Alcoholic drunkenness is equally devoid of conscience and shame. It goes everywhere, without invitation or welcome. Whatever it touches, it soils. It degrades and disfigures everything within the range of its influence—whether the familiar affairs of every-day life, or the noblest efforts of human genius.

Drunkenness really seems to be insanity—reinforced and doubled—lunacy itself run mad.

PRACTICAL OBSERVATIONS ON THE PHYSIOLOGICAL ACTION AND THERAPEUTIC USES OF SOLANUM NIGRUM AND ATROPA-BELLADONNA.

By T. G. STEPHENS, M.D.,
SIDNEY, IOWA.

IT is quite an undertaking for an obscure doctor, in an obscure village, to attempt to write an article for a medical journal whose standard is as high as that of the TIMES AND REGISTER.

I was called to attend a family consisting of husband, wife, and three children, who were supposed to have been poisoned by something which they had eaten for breakfast. I found some of them suffering from pain in the stomach, attended with vomiting, whilst others were harassed with nausea and retching, dryness of the mouth and throat, and dilated pupils; the entire number perspiring and showing signs of stupor. The father stated that the family had eaten freely of buck or beechwheat cakes, and that he had raised the cereal from which they had been made. On inquiry as to whether he knew what black or common nightshade was, he answered in the negative; but, after giving him the general character or scientific description of the plant, he stated that it grew in his yard, garden and fields, and that he had seen it growing amongst the buckwheat. By a little further investigation we found some of the dead plants standing along the side of the field in which the grain had grown. The toxic effects of the supposed plant soon passed off with but little treatment, leaving the family in apparently as good condition as before.

The black nightshade is of foreign nativity, but has become quite common throughout the United States. The entire plant is said to possess narcotic properties, and was at an early date made officinal—afterwards omitted. It had almost fallen into entire neglect until the attention of the medical profession was again called to it by M. Gattacker, Surgeon of Westminster Hospital; in 1757 he used it for foul and painful chronic ulcers, scorbutic eruptions, and ulcers of a cancerous nature. Dioscorides, the celebrated Greek physician and botanist of Anagarba, who is supposed to have lived in the time of Nero, says the ancients used it as an external application, either in the form of poultice or its expressed juice in a great variety of diseases. At present there is no preparation made from solanum nigrum (common nightshade)—at least, we find no mention of any preparation in any of the pharmaceutical or medical text books.

Botanical description.—Is annual, deciduous and herbaceous; height from twelve to eighteen inches; homely, and of a dark green color; the stem branched and often spreading, roughened angles; the leaves ovate toothed; flowers small and white, in lateral clusters, drooping; berries round, and black when ripe. The nightshade family belongs to the natural order Solanaceæ, including an extensive genus, especially as we approach the tropical regions; the members of this order are composed of both herbs and shrubs, but mostly of the former, some yielding nutritious and wholesome food, including the potato — S. tuberosum,—whilst others are powerfully narcotic, and furnish valuable medicinal agents; the narcotic properties depending upon alkaloids, and the narcotism induced by some of them have the peculiarity of producing phantoms and *dilation* of the pupils; unlike opium, whose effects are at first exhilarating, and rarely giving rise to delusions, after a certain length of time the patient passes into a calm sleep, filled with pleasing imaginations, and, if the dose is excessive, *contracted* pupils.

In connection with the common nightshade we will mention one of its congeners—atropa belladonna, deadly nightshade—the most important one of the entire family. The word is a compound one, of the Greek and Italian languages; atropa signifying the name of one of the Fates, who was supposed to cut the thread of human life, whilst belladonna is taken from the Italian language and means a handsome lady, because the ladies of Italy used it as a cosmetic to take away the too florid hue of their faces.

The deadly nightshade has a very remarkable history. The earliest definite notice we have of it occurs in the work of Fragus (A. D. 1532), who calls it *solanum hortense nigrum.* Buchanan relates that the Scots mixed the juice of this plant with the bread and drink which, by their truce, they were to supply the Danes, which so intoxicated them that they killed the greater portion of Swend's army while asleep. Shakspeare is supposed to refer to it under the name "insane root." Belladonna is a native of Asia and Italy, where it grows without attention, and has been introduced into other parts of the Old World, as well as in the New one, where it does well under cultivation, retaining all of its activity, but is not raised in such quantities as to become a commodity; manufacturing pharmacists depending upon that which is imported from Europe. It is a powerful narcotic poison; herbivorous animals and birds are said to be but little affected by doses which are fatal to carnivorous. For the relief of pain belladonna more closely approximates opium than any other narcotic with which we are acquainted. Atropine, as the French call it, the active principle of the plant, is obtained from the dried roots in the form of an alkaloid; the young plants are said to yield a greater per cent. of solid extract, and that the extract itself is much richer and more uniform in yield of atropine. When used subcutaneously its action is very prompt. In cases where a narcotic is indicated, and opium not well borne in consequence of an existing idiosyncrasy, belladonna will generally fill its place. Where there is irritation of the vascular granulations of the hypertrophied mucous membrane of the bowels, belladonna is often contraindicated, being laxative, and producing colicky pains; it is liable to give rise to tormina and painful intestinal tenesmus.

Therapy.—The greatest uses of belladonna are in neuralgia and spasmodic affections, especially those

having their origin in the pelvis. For irritation of the bladder or incontinence of urine caused by irritation of the detrusor muscle, the solid extract of belladonna excels all other narcotics, taken noon and night; and, as the root grows in different localities, there is not an exact uniformity of strength in this preparation, so it is better to commence with one-fourth of a grain and increase to one-half, or more, until its characteristic effects are experienced.

For enuresis nocturna:

℞.—Extract of belladonna sol. ..... gr. ij.
Aquæ puræ ..... f℥ij.
Fiat. sol. et add:
Extract. pichi ..... f℥j.
Syr. gaultheriæ ..... ℥vij.
M.—Sig. A teaspoonful noon and night for a child five or six years old, gradually increasing the dose if necessary.

In the more intractable cases of neuralgia, belladonna alone is not sufficient, but, by the combination of its alkaloid, sulphate of atropine with the sulphate of morphine, we have a more reliable remedy, one which may be hypodermically used with better results and fewer relapses than when given separately, and the medicine borne for a much longer period without the unpleasant effects which usually follow the prolonged use of either one alone. Their actions are synergetic, one remedy antagonizing the bad effects of the other. Localization of hypodermic injections, as a rule, is not necessary to benefit a given part; neither is it necessary to inject the painful site, although there are exceptional cases in sciatica and dorso-intercostal neuralgia; whether the latter be associated with herpes zoster or not, I have received the best results from localization. The good effects of the medicine in this way may be on account of some anatomical change in the neurilemma, or in the parts surroundiug the nerve. In the treatment of intercostal neuralgia, which is the most frequent form, the medicine should be injected into one or more of the points douloureux of Valleix, which are generally quite sensitive; also, in the treatment of sciatica, it is better to inject into the areolar tissue surrounding the nerve, along the ham and peroneal surface of the leg.

In the treatment of neuralgia of the fifth pair of nerves, whether depending upon structural changes or not, hypodermic injections at a remote part is quite satisfactory. I have in charge a gentleman, in his seventy-seventh year, whose upper lip, a part of his nose, and the greater portion of the soft parts of one side of his face have sloughed in consequence of an epithelial cancer, and, as a temporary expedient, a single injection into the arm gives comparative relief from pain, arresting the excessive flow of saliva, and other discharges, in a marked degree; superseding all other medicaments in the case, having used it during the last eight months two hundred and eighty times, administering it, with the exception of three or four times, in the posterior aspects of the forearms. The only observable difference in its effects since this course was adopted is that its action is not quite as prompt, the same sized dose having been used the entire time; the patient occasionally takes, in my absence, a dose of morphine. The following formula is a very suitable one in the foregoing cases, and can be obtained in the form of soluble hypodermic tablets, one constituting a dose, at the same time giving due attention to any anomalies that may present themselves:

℞.—Atropinæ sulph. ..... gr. $\frac{1}{100}$.
Morphinæ sulph. ..... gr. $\frac{1}{4}$.
M.—Fiat tablet No. 1.

Dissolve this in thirty drops of water, and use hypodermically as the occasion requires, persevering in the treatment, if necessary, until symptoms of incipient poisoning is produced. In cases where we expect to administer one or both of the remedies for a considerable length of time, it is better to combine them in the beginning, which lessens the tendency to headache and morphinism, differentiating if necessary.

SUPPURATING ULCER OF THE CORNEA.

By EDWARD JACKSON, A.M., M.D.,
Professor of Diseases of the Eye in the Philadelphia Polyclinic.

FOR the present purpose it is convenient to regard corneal ulcers as divided into two classes, the simple and the suppurating.

In the former the loss of substance constituting the ulcer is surrounded by clear, apparently normal corneal tissue, or by tissue moderately infiltrated with plastic material; in the latter the surrounding tissue is, to some extent, softened and infiltrated with pus.

The simple ulcers include those ordinarily seen in neuro-paralytic, malarial, or phlyctenular keratitis, and many of those due to injury of the cornea, or accompanying catarrhal forms of conjunctivitis. The suppurating ulcers arise from infection, sometimes from primary infection either on the surface constituting an ulcer from the start, sometimes from deeper infection, starting as corneal abscess. Certain injuries are particularly prone to give rise to suppurating ulcers.

The simple ulcer, too, is quite liable to become infected, and pass over into the suppurating class. While, on the other hand, it is the endeavor of the surgeon by appropriate treatment to deprive the suppurating ulcer of its peculiar character, and carry it over into the class of the simple.

The majority of ulcers that perforate the cornea belong to the class we are considering, and a very large proportion of suppurating ulcers, unless checked by appropriate treatment, go on to perforation of the cornea.

The management of one of these cases, so long as it maintains its special suppurative character, is always a cause of anxiety and annoyance to the surgeon. For not only is there danger of perforation leaving adherent leucoma and permanent opacity of the cornea, but in a considerable proportion of cases the pus makes its way into deeper parts of the cornea, causing onyx or hypopyon, and the suppurative process extending still further is liable to cause the complete functional destruction of the eye.

In this form of ulcer the general disturbance of the whole eye-ball is usually considerable, the pain severe, the hyperæmia marked. But the diagnosis is to be made principally by inspection of the ulcer itself. Plastic exudation into the cornea, and chronic opacities of the cornea are gray. Purulent opacity is yellowish. Sometimes fine vessels give to other opacities a somewhat yellow color, but in such cases careful examination under a strong lens will reveal the individual vessels. In addition to the yellowish color it presents, the tissue involved in the suppurative process is greatly softened.

Passing directly from the practical matter of diagnosis to the practical matter of treatment, the gravity of this affection has, with reason, been held to justify recourse to vigorous measures of treatment. In the more serious cases, especially the so-called *ulcus serpens*, incision extending through all the layers of the cornea, and from the sound tissue on one side to

the sound tissue on the other, was a few years ago the accepted standard treatment. Milder cases were to be met by a vigorous scraping away of the surface of the ulcer. More recently the actual cautery, or the galvano-cautery, for the destruction by heat of the infected tissue, has been quite generally resorted to with good results. And it is the treatment to which I should resort if the following method had not given even better results, as to the amount of permanent opacity left by the disease.

The surface of the ulcer is to be carefully scraped with a blunt instrument, such as the cornea spud, until all tissue soft enough to be readily scraped away has been so removed, and the purulent exudate has been squeezed out of the tissue around it. This manipulation reveals the depth of the ulcer, considerably narrows the area of noticeable infiltration, and enables the surgeon to make his subsequent application directly to the seat of conflict between the living tissue and the invading pyogenic bacteria. The scraping should be repeated whenever any renewed extension of the area of purulent infiltration is noticeable; whether that be in six, twelve, or twenty-four hours; and so often as there is this indication for it.

Immediately after each scraping the surface of the ulcer is to be thoroughly washed with a solution of bichloride of mercury of from 1-1000 to 1-3000. This is done by filling the ordinary rubber-bulb pipette or dropper with the solution, holding its nozzle in close proximity to the ulcer, and then ejecting the fluid with considerable force against its surface.

In addition, the patient is to have the eye thoroughly cleansed every one, two, or three hours with a solution of mercuric chloride of 1-3000 or 1-5000. And two or three times a day the closed lids are to be bathed, for five minutes or longer, with water as hot as the patient can bear. The length of hot warm applications is to be proportioned inversely to the inflammatory hyperæmia. When the general inflammatory reaction seems greatly below what should attend the suppurative process going on in the cornea, each application of hot water may be continued fifteen or twenty minutes, and the application may be more frequently repeated.

The pain of this scraping and washing may be brought within reasonable limits by the use of cocaine. When corneal abscess is to be dealt with, it is to be opened freely, and at once, and then treated as a suppurating ulcer. The eyes should be kept at rest for some days, and perhaps shaded during this time, and anything like poulticing or bandaging carefully avoided. As the ulcer loses its special suppurative character, this special line of treatment may be abandoned, except that the use of the milder solution of mercuric chloride should not be given up until the healing is pretty well completed.

The line of treatment thus indicated is essentially the one I have followed for a little over two and a half years. The results obtained with it have been very satisfactory. Of the eighteen cases of suppupurating ulcer that have, during this period, been under my care, but three have gone on to perforation of the cornea, and these three are exceptions that may truly be said to prove the rule, since they were not at the time the perforation occurred under this treatment.

Case I.—S. H. M., a colored boy, nine years old, was brought to the clinic with an ulcer near the outer margin of the right cornea; this was regarded as a phlyctenular ulcer, and so treated. He neglected to return until the fourth day, when the ulcer had perforated, allowing a small round prolapse of the iris. The margins of the ulcer presented purulent infiltration. They were treated by the above method, and quickly healed. Eserine failed to produce the prolapse, which was snipped off three weeks later. The eye was left with a small peripheral adherent leucoma, a free circular pupil and good vision.

Case II.—A girl, aged three and a half years, was brought with a central suppurating ulcer of the cornea, which was treated according to the plan recommended. Next day there was great improvement. Two weeks later she was brought back with the ulcer greatly extended, and its floor and sides a mass of sloughing tissue. The history given was that after the second visit it seemed so nearly well that the mother thought it not worth while to return, and in two or three days discontinued the use of the bichloride solution at home. It had been getting worse again for nearly a week. On attempting to fix the eye for the scraping, the floor of the ulcer gave way, and the aqueous humor escaped with a spurt. The treatment was now regularly pursued, and the ulcer healed rapidly, leaving no synechia, but a central leucoma preventing any good vision.

Case III.—A child, three years old. Brought to the clinic in my absence, and treated as a case of phlyctenular ulcer without scraping or bichloride. At the second visit the floor of the ulcer was found sloughy, and it readily perforated during the scraping. Recovery was prompt, with a small leucoma and one thread-like synechia.

It will be noted that in two of these cases perforation occurred at the time of the scraping, but it cannot be blamed on the special instrument or manipulation employed. It would be quite as likely to follow any other local manipulation and treatment. Possibly in some such cases it may be avoided by a previous tapping of the anterior chamber through some other part of the cornia, a procedure I resorted to with success in one of the cases treated after this plan.

Hueppe recommends as a diet in cholera:

R.—Vitelli ovi	. . . . .	No. ij.
Sp. vini Gall	. . . . .	℥j.
Syr. rhataniæ	. . . . .	℥ss.
Aq. cinnamomi	. . . . .	℥ss.

M.—S. ℥ss every half or quarter hour.

Formula for Diuretin:—

R.—Diuretin	. . . . .	gr. lxxv to ʒij.
Syrupi	. . . . .	℥ij.
Aquæ menth	. . . . .	℥iij.
Aquæ dest.	. . . . . q. s. ad.	℥vj.

M.—S. ℥ss every half to one hour.

M. Babchinski, a Russian physician, had his son attacked with severe diphtheria. An attack of facial erysipelas supervened, and a sudden change was produced in the condition of the patient; the fever fell, the exudation disappeared, and the child recovered in a short time. The physician observed with many other patients a like improvement follow erysipelas; and in one case the erysipelas had attacked a limb. These facts suggested the idea of inoculation with erysipelatous blood. This was done; and the child was cured of its diphtheria. Similar success was invariably obtained by inoculations with cultures on agar-agar. No other remedy was employed.

THE ECLECTICS.

A WRITER in the *American Medical Journal* undertakes to reply to our remarks in a recent issue of this journal on the standing of eclecticism. He does not accept our definition of their principles, but says that the statement of their limitation to the use of certain drugs is incorrect; and that the eclectic is "perfectly free to select his remedies from any source whatsoever — whether from the vegetable, mineral, animal, or any other kingdom." "We claim the glorious privilege of using any and all remedies that will aid us in restoring the patient to health."

Then what is there left to eclecticism to justify its existence as a separate school? Either the eclectic is limited to the use of certain remedies, or he is not. If he is not limited, but free to use whatever he believes to be best, he occupies the ground of the regular school. In that case, the reasons for the separate existence of the eclectic school must be sought elsewhere than in a difference in therapeutics. We have carefully perused the article in the *American Medical Journal*, and failed to find any exposition of eclectic principles which merits consideration. We quote:

> From their extensive investigation and experience they have learned that irreparable injury can be done to the human system by a reckless administration of minerals, and, consequently, give them more conservatively and carefully than allopaths. They have a great advantage over the allopaths, from the fact that the latter are not familiar with many drugs outside of the mineral kingdom, and, consequently, have not so great therapeutic resources as eclectics.

This is disappointing. From his outspoken repudiation of therapeutic limitation, we hoped the writer would give us something tangible in the way of an exposition of principles. All there is in the above is simply the assertion that eclectics, as a class, give minerals less "recklessly" than do regulars, and that the former are more familiar with many non-mineral drugs. This is sheer nonsense. Even if it were true, it would not constitute as good a reason for the existence of a separate school as the celebrated dispute over a diphthong was for dividing the Church. We may believe that our professional brother gives calomel more freely than we would; but that is his affair, not ours; and if that constituted a legitimate reason for separating into different sects, then every physician would form a school of his own, isolated from his fellows. Individual preference in the matter of treatment is not, then, a sufficient excuse for the existence of a separate school. No eclectic can possibly be farther apart from the regular in their honest belief and practice than is Tait from Apostoli, Koch from Virchow, Pasteur from Peter. Yet the regular school is broad enough to cover all these, and many more who are diametrically opposite in their beliefs, and have no hesitancy in expressing their views as to each other. Absolute freedom as to belief and practice rules in the regular medical school; and what more can any one ask? There is no law by which one *must* do any one thing but what he believes to be his duty by his patient. That platform would seem to be broad enough for any one to stand upon.

The true reasons for the existence of separate sects in medicine are political rather than scientific. Many eclectics have not received any medical education worthy of the name. Some have. Others have, by their native intelligence and industry, made up in actual practice for the defects in their collegiate course — as has every physician who ever left the halls of the best college in existence. It is to this class we have endeavored to draw public attention; to the men who are fully qualified to practice medicine, whose practice and belief are the same as our own, but who are compelled, by an absurd technicality in our own regulations, to remain with a class of practitioners with whom they have no sympathy, or else live in professional isolation.

We speak from the standpoint of those to whom medical science is dear, medical politics distasteful. Everything that favors the rise and perpetuation of sects in medicine injures the true cause in just so far as it withdraws the thoughts of men from the study of strictly professional work. Every page which is filled with denunciations of other schools is that much lost to science. Judging from some of the sectarian journals that reach our table, so much of the time of our friends is spent in portraying "allopathic" wickedness that there can be but little left for study. If the eclectic has discovered truths that escaped our ken, he should come right in among us and disseminate them; and perhaps we, in our turn, may be able to give him a little increase of knowledge.

ACCLIMATIZATION.

AS the broad fields of the great West are becoming rapidly occupied, the time draws nearer when new outlets for our surplus population must be found. England turns her attention more and more towards the tropics. India and Africa prove more attractive than the colder regions of the Canadian Dominion. If we follow this example, Mexico and Cuba will probably afford us the needed outlet; and in that case the question of acclimatization will become important. One of the most interesting papers

presented at the late Congress was upon this subject, by Prof. Stokvis. The tropical races differ in some respects from the natives of the high latitudes. The former breathe more rapidly, have smaller lung expansion, the thorax is less in circumference, abominal respiration less marked, the pulse is faster and of less tension, the abdominal organs are richer in blood; they sweat more and urinate less, they are over half a degree warmer, and weigh less in comparison to their height. They have less acute special senses, less power of mind and body, but greater sexual vigor.

These peculiarities Stokvis believes to be less due to race than to climate; as Europeans settling in the tropics tend to assume the type of the natives. Tissue metabolism lessens, urea lessens, and the inorganic salts in the urine increase. The blood is unaltered. As the European adapts himself easily to the heat-changes, so he also resists atmospheric changes better and suffers less from pulmonary diseases than the native. Sunstroke is more likely to affect the European, but occurs too seldom to be an important factor. Gastro-intestinal affections, skin diseases, and hepatic disorders are more common among Europeans; but the abuse of alcohol must be taken into account. The European must avoid excesses of all kind, and observe hygienic rules; and when this is done the mortality is strikingly lessened. During the first half of this century the death-rate of the English troops in India was 84.6 per 1,000; it has since fallen, with the observance of improving hygiene, until from 1879 to 1887 the mortality was but 16.27 per 1,000.

As to the specially tropical diseases, malaria affects the natives in India equally with the whites. Typhoid is more common with the latter. Yellow fever attacks new-comers chiefly, who have not had time to become acclimated. Dysentery and cholera retreat before the advance of hygiene; the mortality from the latter having fallen from 18.6 per 1,000, in 1868, to 3 per 1,000. Beri-beri attacks all races alike. Stokvis' conclusion is that the European has a power of resistance equal or superior to the natives; but that this is gradually diminished by residence in the tropics; so that the European Creole is, bodily and mentally, inferior to the European.

For many reasons, it is most desirable that the outlet for our people should be found in the North.

Annotations.

STATE OF URINE IN GENERAL PARALYSIS.

M. LAILLIER remarks as follows upon the above subject: He has observed certain modifications of the nature of delirium presented by general paralytics. He states that in the depressing delirium which precedes general paralysis, the total amount of substances eliminated by the urine descends below a physiological proportion. In anxious delirium, on the contrary, he notes an exaggeration of the salts in the urine, notwithstanding the insufficient nutrition of patients.

In the outset of general paralysis carbonate of ammonia is not to be found in urine; but during the later stages it is in abundance.

Laillier has never met diabetes in general paralysis, and among diabetic insane whom he has observed not one of them has ever become paralytic.

—*Le Bulletin Médical.*

A SINGULAR cigarette accident occurred in Paris. An elderly gentleman received a slap on the back; the cigarette he had in his mouth disappeared; and two months later a circumscribed pneumonia developed, with pulmonary œdema and feeble heart. Two months of this condition elapsed, when the missing cigarette was coughed out. The pulmonary symptoms persisted for some months, and had not entirely disappeared at the expiration of a year. The remarkable toleration of the foreign body by the bronchus is to be explained partly by the patient's age and partly by the local sedation caused by the tobacco.

BEFORE the Academy of Medicine, at the sitting of August 5, Prof. Sée read an article upon The Use of Cannabis Indica in the Treatment of Neuroses and Gastric Dyspepsia, from which we extract the following résumé:

Cannabis is a vegetable stomach sedative, without any of the inconvenience of such narcotics as opium and chloral; of such absorbents as bismuth; of such common sedatives as bromides; of antipyrine or other drugs of this class, which invariably produce enfeebling effects upon the digestive tubes.

The action of cannabis necessarily involves the aid of other curative methods as indicated. It demands the adoption of such sanitary food regulations as recent physiological researches have demonstrated to be of use in stomach digestion.

Stomach digestion is increased by cannabis if the functions be impaired by a paralytic condition of the nerves of these organs, or by a surplus of hydrochloric acid. In the latter event it produces no improvement. All it can do is to render digestion less painful. It cannot make it more effective.

Intestinal indigestion, on the contrary, is at once relieved by this drug.

Upon such concomitant phenomena as vertigo, migraine, insomnia, palpitation, and even dyspnœa it acts well, often annihilating these painful symptoms. From all of which we deduce the fact that it would be well for this comparatively little used drug to be brought into open notice.

IN the August number of the *Berliner Klinische Wochenschrift* is an article by Dujardin-Beaumetz upon Dilatation of the Stomach as a Cause of Neurasthenia, which was read before the late medical congress at Berlin.

After speaking at length of the relations which existed between diseases of the stomach and of the nervous system, he speaks as follows regarding the treatment of this particular form:

"What is the treatment that gives the best result in these cases of neurasthenia of a gastric origin? It is that which has for its basis gastro-intestinal antisepsis—antisepsis which is realized by the employment of the following means:

"(*a*) Employment of such antiseptics as salicylate of bismuth, naphthol-β, and salol.

"(*b*) Evacuation of toxics by proper laxatives where there is constipation, and among those patients which have diarrhœa the employment of intestinal lavage with solutions of one to a thousand of naphthol.

"(c) Employment of alimentary hygiene which will reduce to their minimum food poisons, a condition which is obtained by the use of a vegetable régime composed of eggs, starches, fresh vegetables and fruit. Fish, game, mollusks, shell-fish and old cheese are forbidden. It is better to use food rendered imputrescible by prolonged cooking, as few meats as possible, laxative drinks.

"To this medical antisepsis should be united massage, used as aid to gymnastics and hydrotherapy.

"These are the conclusions that I wish to make public regarding a disease that has grown so common to-day: dilatation of the stomach followed by neurasthenia.

Cincinnati Letter.

DR. S. C. AYRES has returned from the Rocky Mountains, where he went to escape the hay fever.

Dr. L. J. Krouse has returned from New York, where he spent six weeks looking up the latest in his specialty.

Dr. A. W. Johnstone, of Danville, Ky., has removed to Cincinnati, and is in partnership with Dr. T. A. Reamy in his private hospital for women.

The Cincinnati Obstetrical Society held its September meeting at the residence of Dr. E. S. McKee. The subject for discussion was Obesity in Its Relation to Menstruation and Conception, which was opened by a paper by Dr. McKee. The next meeting will be held at the residence of Dr. T. A. Reamy, the third Thursday evening in October, being deferred one week on account of a number of members being in attendance at the Mississippi Valley Medical Association at Louisville, Ky., October 8, 9, and 10, 1890.

Drs. Max Thorner, Max Koehler, W. W. Seely, and W. M. Rhoads have returned from the International Congress at Berlin.

Dr. W. S. Christopher, Demonstrator of Chemistry, Medical College of Ohio, has been called to the Chair of Theory and Practice, University of Michigan, and has departed for his new field of labor.

The Order of Deaconesses has a strong advocate in Cincinnati in the person of Dr. E. G. Zinke. This is a German organization for the training of nurses for the sick, be they rich or poor. The rich, the doctor said, could not get competent nursing, because the demand largely exceeded the supply; the poor could not get it for love or money, for both were scarce with them. He considered that the physicians of this country, and a suffering people in general, had a great lack of competent nurses. In a recent address for the benefit of this order he gave a careful history of its origin, growth, and development. Lodges organized for the benefit of the sick do a good work, but nurses supplied in rotation this way are not always beneficial. He gave a graphic description of nursing by friends and relatives, where one advised this, the other that. All display a sincere interest and kind spirit, but seldom, very seldom, do they know properly the function of a nurse, and frequently do more harm than good. The doctor was speaking to a German audience, and said: "We are justly proud of our German origin and descent, but we also rejoice that we have become Americans. We esteem the land of our fathers in the sense in which well-trained children esteem their parents, but we stand by the land of our adoption as an honorable man should by the wife of his bosom. We owe to our adopted country our entire strength, our noblest thoughts and feelings—nay, our most affectionate attention."

Dr. J. T. Whittaker was married during the summer vacation to Miss Virginia Joy, of St. Louis. The doctor and his bride took a trip to Europe, which is said to have been a very Joyous one. It is said that when the doctor went to ask for his bride, he was so filled with Joy that his tongue, usually his most obedient servant, was paralyzed with Joy. The old gentleman, seeing his embarrassment, surmised his wishes, and said, with as brave an air as possible, "Well, I don't care a Whit—tak 'er." The doctor's friends, who are legion, wish him and his wife a long and Joyful married life.

Dr. T. A. Reamy, in a recent clinical lecture, spoke very interestingly on the subject of the Early Diagnosis of Cancer of the Uterus. He said: I have had exceptional cases at twenty-two and twenty-three years of age, but if the patient is beyond thirty, or if she has had children or miscarriages, insist on an examination, and see if she may not have carcinoma in the first degree. Hemorrhage and wasting discharge are the early symptoms. Do not wait for pain and the characteristic odor, the cachexia or pallor. Do not wait especially for odor and pain. Make a digital examination. You can generally detect a roughness or breaking down of tissue, and then a visual examination by the speculus should be made. We may find ectropion and may be degeneration, and think we have cancer, when we have not. If, in operating for a lacerated cervix, we find suspicious looking tissue, cut it away, for if the tissue is not an epithelial growth it is next door to it, and should come away. The importance of the early diagnosis of cancer of the uterus, is emphasized by the fact that two thirds of my one hundred and fifty cases per annum, which come under my care, have advanced so far, one half of them even before they come under the care of the family physician, as to make a possible cure by operative proceedings very doubtful. Why is the early diagnosis of this disease so frequent? For the reason that the real cause of cancer is not known. It is, nevertheless, true that with the exception of one single authority of prominence, Sir James Paget, so far as I am acquainted with the opinions of authors, all agree in the belief that cancer is primarily a local disease. There is very probable predisposition in constitutions, tissue inheritance, yet the consensus of opinion is that cancer is a local disease.

The early diagnosis of cancer is one of the most important points in the practice of our art. Its importance cannot be overestimated. If we are to do anything we can do it with so much more hope of success if done early. Many of the cases met in hospital practice are so far advanced in the disease before they seek the advice of the surgeon, and the operation is consequently more extensive and attended by more danger than if an early diagnosis had been made and surgical treatment employed. He had been on duty at the Good Samaritan Hospital for eighteen years, and the number of cases which came to him there early enough was very small indeed. Medical treatment amounts to nothing. Surgical treatment if employed early may save, so hence this is the only treatment worthy of consideration. This woman gives a history of prolonged menstruation. Whenever a woman comes to you between the ages of thirty-five and fifty years, and tells you that she is menstruating too freely, too long, or at intermenstrual periods, do not give way to the popular opinion that the woman is suffering from the change of life. The irregularity in menstruation, which signals the approach of the

menopause, is that the woman will miss a period or two and not have too frequent or excessive menstruation. This woman menstruated too freely, then had an occasional show at intermenstrual period.

It cannot be said that much progress has been made during the past forty years as regards the recognition of fully developed cancer. Bennett's monograph on Cancerous and Cancroid Growths, published in 1849, shows a pretty thorough knowledge of the subject under consideration. He says: "The microscope alone, and independently of all other kinds of observation, can seldom determine the presence or absence of cancer." With regard to the microscopical diagnosis of cancer, we have not improved very much over Bennett. This distinguished author was also well up on other points for his day. He says, in regard to the local origin of cancer: "A cancerous growth is for some time purely local. In this indolent state a tumor may often be excised and permanently eradicated. Even when the growth has become moderately cancerous, ablation is said to have been occasionally followed by success." "There was a time," says this author, "when phthisis was thought to be necessarily fatal. Morbid anatomy has expelled that error, as it will doubtless do regarding cancer."

At the present time, however, surgeons generally unite careful microscopical examination of the structures in a suspected case with the clinical study and microscopical appearances, thus recognizing the malignant character of tumors much earlier than formerly. Here lies one of the most important advances. It points the way to extirpation of the growth in its earlier stages, while it is yet local; thus largely increasing the chances of cure. Virchow's experience with the Emperor Frederick shows how difficult it is sometimes for the most experienced pathologist to give a positive opinion regarding the malignancy of a growth, especially when so located as to permit of the removal of a very small portion for microscopical examination. However, our knowledge of cancer, especially cancer of the uterus and the breast, has been much extended during the past ten years. Surgeons have also learned to distinguish more accurately operable and inoperable cases, and thus save the patient from severe, useless, and dangerous operations. These conservative results, derived from our knowledge, are next in importance to the cure of disease by early operation. It is no small matter to save a surgeon from a surgical operation which could do no good. The benign affections of the cervix uteri which may be confounded with the malignant are chronic inflammation, endometrial inflammation with its results, erosions, granular degenerations, ectropium.

Pamphlets.

The Pharmacology of the Newer Materia Medica. Embracing the Botany, Chemistry, Pharmacy, and Therapeutics of New Remedies. Being the results of the collective investigation of new remedies, under the "Working Bulletin" system, properly arranged, classified, indexed, and placed at the disposal of the medical profession. Issued in monthly parts. Subscription price, $2.00, in advance. Single copies, 25 cents each. Detroit, Mich.: George S. Davis.

This, and the five succeeding numbers, contain an epitome of the clinical reports received upon the later additions to our materia medica. They are precisely what the physician wants who desires to employ these agents, and wishes to have the guidance of those who have already tested them. The first part begins with Adhatoda Vasica, and the list is taken up alphabetically. Parts V and VI treat of coca and cocaine.

The Vagus Treatment of Cholera, as Exemplified in Returns from the Cholera Hospital of Malta During the Epidemic of 1887. By Alexander Harkin, M.D., F.R.C.S.

Dr. Harkin's method of treating the choleraic group has been already presented to our readers. Since the publication of his article we have seen, in several journals, commendation of his treatment, and objections to his pathology similar to those we suggested at the time. Several physicians have personally reported to the writer unexpected and complete success in cases of cholera infantum with severe vomiting, by the application of blistering liquid over the pneumogastric in the neck. The pamphlet before us gives further records of experience in the use of this remedy in true cholera.

The Study of Bacteriology in Medicine. By Frank S. Billings, M.D., Chicago, Ill.

Description of a Series of Tests for the Detection and Determination of Subnormal Color-perception (Color-blindness). Designed for use in Railway Service. By Charles A. Oliver, M.D., Philadelphia.

Stricture of the Rectum. A Study of Ninety-six Cases. By Chas. B. Kelsey, M.D., New York.

Massage. A Primer for Nurses. By Sarah E. Post, M.D. New York: The Nightingale Pub. Co., 13 W. Forty-second street. 1890.

Just what one wants to give a nurse enough information on massage to enable her to obey directions intelligently.

Some Conditions of Adolescence in which Fellows' Hypophosphites is Beneficial. Part IX. Jas. I. Fellows, 56, Holborne Viaduct, E. C., 1889.

Proceedings of the First Annual Meeting of the Tri-State Medical Association of Alabama, Georgia, and Tennessee. Held in Chattanooga, Tenn., October 15 and 16, 1889.

Recent Therapeutical Notes on the Use of "Papoid" (Carica Papaya) in the Treatment of Dyspepsia and Diphtheria. New York: Johnson & Johnson, 92 William street.

Transaction of the American Dermatological Association at its Thirteenth Annual Meeting, held at the Boston Medical Library, Boston, Mass., September, 1889. Official report of the proceedings by the Secretary, George H. Tilden, M.D. New York: 1889.

Ueber das Aristol. Von Dr. P. J. Eichhoff, Oberarzt der dermatologischen und syphilidologischen Abtheilung in den städtischen Krankenanstalten zu Elberfeld. Sonderabdruck aus der *Deutschen Medicinischen Wochenschrift*, 1890, No. 27. Redacteur: Sanitätsrath Dr. S. Guttmann. Leipzig: Verlag von Georg Thieme. 1890.

Clinical Observations on the Action of Phenacetine-Bayer. By Dr. Dujardin-Beaumetz (Paris), and others.

The Relation of Eye-strain to General Medicine. By George M. Gould, M.D., Ophthalmic Surgeon to the Philadelphia Hospital. From *The Medical News*, August 23, 1890.

Address in Hygiene. By Thomas J. Mays, M.D., of Philadelphia. Reprinted from the Transactions of the Medical Society of the State of Pennsylvania, June, 1890.

An Explanation of the Phenomena of Immunity and Contagion, Based Upon the Action of Physical and Biological Laws. By J. W. McLaughlin, M.D., Austin, Texas. Reprint from Transactions T. S. M. A., 1890.

International American Conference:

Report and Recommendations on Postal and Cable Communication with Central and South America.

Report and Recommendations Concerning a Plan of Arbitration for the Settlement of Disputes Between the American Republics.

Report and Recommendations Concerning Sanitary and Quarantine Regulations in Commerce with the American Republics. Washington: Government Printing Office. 1890.

Spinal Surgery. A Report of Eight Cases. By Robert Abbé, M.D. Reprinted from the *Medical Record*.

Three Cases of Tumor of the Frontal Lobe. By W. Gilman Thompson, M.D. From *The Medical News*.

Tenth Annual Report of the State Board of Health of New York. Transmitted to the Legislature February 20, 1890. Albany: James B. Lyon, State Printer. 1890.

The Medical Digest.

In a case of profound depression from a discharging empyema, Smith (*Med. World*) employed oxygen enemata with gratifying results.

Stom says that there is but slight evidence of insanity resuting from gynecological work; while the overwhelming mass of data showing insanity to have resulted from disease of the generative organs and the number cured by gynecological treatment, should forever silence captious treatment.

I have used for more than two years the sulphocarbolate of zinc, and find it an excellent remedy. I use it mostly in intestinal diseases of children, and give from one-sixth to one-half gr. doses. Adults take one to two gr. doses every two to four hours. It is astringent and antiseptic, and can be given in combination with bismuth, etc., and repeated as necessary.—Bolton, *Med. World.*

White, in *The Lancet*, reports a case of hepatic abscess. The symptoms were fever, jaundice, coated tongue, colorless feces, and turbid urine. A hard, painful, and tender tumor was found in the hypogastrium, below and to the right of the ensiform cartilage. The abscess was opened, and a large number of gall-stones evacuated from time to time during the following year, leaving the liver much reduced in size.

The essential pathology of paroxysmal hemoglobinuria appears to consist in the ready breaking down of corpuscles of lessened resistance under the influence of cold, and the after appearance in the urine of the products of such destruction; this ready breaking down of corpuscles being apparently the final result of an imperfect power of production in the blood-forming organs, caused in turn by the baneful influence of syphilis, or possibly, malaria or gout.

—Copeman, in *Practitioner.*

Maternal and Paternal Impressions.—In the *Southern California Practitioner*, Brown relates a case in which a woman went to a circus, fainted at sight of the clown, and three days later gave birth to a boy, on whose face appeared the similitude of the clown's painted countenance. In a few weeks the colors faded away.

In the same journal, Bullard describes six cases of paternal impressions! He accounts for these by supposing that the parent who causes the impression hypnotizes the child in utero. Very good.

Milk Poisoned by Plants.—I have had two cases of infantile gastric and intestinal trouble in the last three years, which I think were undoubtedly produced by the children drinking milk from cows that had been feeding on "tumble weed."

The symptoms indicate a mixture of cholera infantum and dysentery. The first case, in a strong child about one year old, recovered after a severe illness, but did not grow any for a year or more. The second case, a weakly child about five months old, died.

In the first case the disease was arrested by bismuth subnitrate, blackberry brandy and listerine by stomach, and large injections of cold water fresh from the well. The case was ten miles in the country, and I could not get ice.

Rhea, in *Med. World.*

Dr. Cséri, of Budapest, publishes in the *Wiener Medicinische Wochenschrift* an account of a mechanical plan of treatment of chronic dyspepsia, which he has lately been carrying out with favorable results. The plan consists mainly in suitable dieting and in a peculiar kind of massage. The author practices the latter when the stomach is full, about two or three hours after dinner. Changing frequently his mode of proceeding, he strokes and kneads the stomach from the fundus towards the pylorus, first gently and superficially, then more energetically, for ten or fifteen minutes, the patient lying on his back with his legs drawn up and breathing with his mouth open. During the last few minutes the massage is extended to the bowels.—*Lancet.*

Elixir of Burdock Seed as a Menstrual Regulator.—Dr. A. D. Ayer, of Madison, Conn., in too frequent menstruation, recommends a saturated tincture of burdock seeds, mixed with an equal quantity of simple elixir, teaspoonful doses three times a day. He gives it also in menorrhagia and amenorrhœa. The frequency of the dose, of course, is to be adapted to the severity of the case. The doctor recommends that, in cases of married women, an examination should be had in order to exclude lacerations and other local lesions. He sees especial indications for the remedy in the following train of symptoms: "A dirty-looking, leaden-colored skin, full tissues, puffiness under the eyes, with swelling of the feet; urine, as a rule, scanty (excluding the uric acid diathesis); irregularity of bowels—constipation alternating with looseness; inclination to skin eruptions; languid, tired feeling; frontal headache, with beating, thumping feeling at the top of the head, as if something within tapping upward; prickly sensation at the roots of the hair, coming on suddenly, as from a thought, or reading a piece of news, or hearing an unusual noise."—*Med. World.*

Puerperal Eclampsia.—Cecil, in the *Amer. Pract. and News*, describes a case of puerperal convulsions, and gives the following summary of his views upon the management of this affection:

1. Control or modify the convulsions by chloroform.
2. Give chloral with a free hand to prevent their recurrence. This does not interfere with the next step.
3. As this is a disease attributable to non-elimination, obviously the scientific thing to do is to eliminate. The choice of methods is by purgation. Croton oil, jalap, and Rochelle salts are reliable, speedy, and efficient.
4. If the tendency to eclampsia continues after purgation, the question of delivery must be considered.
5. Labor not progressing satisfactorily, delivery may be hastened by rupture of the bag of waters, orificial irritation, Barnes' dilators, forceps, in preference to version, as soon as their application is possible.
6. After free purgation, in the presence of nervous phenomena, before or after delivery, morphine may be given with good effect.
7. Before purgation, morphine, to control convulsive action, must be given in very large doses, and is then no more efficient or reliable than chloral. Its use is contra-indicated because it arrests elimination through every channel; it has a more powerful quieting influence over uterine contractions than chloral; it congests an already congested brain; it retards a prompt convalescence.

SYPHILITIC FEVER IN THE PUERPERAL PERIOD.—A woman of twenty-five years was delivered of a macerated fetus. On her left labium was noticed a little whitish cicatrice, the trace of a chancre some months previously, which had been followed by roseola and vulvar and buccal plaques. When she came to the hospital, all specific manifestations had disappeared under treatment, except intense nocturnal headache, and indurated glands in the cervical region and the knee.

The sequences of the accouchement were at first normal; some odorless lochia, no stomach pain, uterus well retracted, slight mammary congestion, good appetite. Suddenly, on the eighth day, without pain or rigors, the temperature went to 38.5° C. in the morning, and 39° C. in the evening. Suspecting a puerperal infection, the uterus was washed out with Van Swieten's double solution; but the liquid returned clear, without débris. Quinine, fifteen grains. Following the injection, reflex syncope, without rigors, with free sweating.

Next day, temperature 38.5° C., repeated the injection, with the same result. The belly is soft, painless, flat; uterus small, not tender; vaginal touch reveals nothing abnormal; no discharge. That evening a roseola appeared on the breast, which invaded the abdomen and back, and lasted two days. Yet, the general health remained good, pulse regular, strong and of medium frequency, considering the temperature of 40° C.

Specific treatment resulted favorably, and she left the hospital twenty days after the confinement.

—Leblond, in *Le Bulletin Méd.*

BONE-GRAFTING.—In *The Lancet* is reported a case of bone-grafting with decalcified bone chips, at the Edinburgh Royal Infirmary. The case was that of a farmer, aged forty-four, with chronic inflammation of the bursa under the right ligamentum patellæ, and abscess in the head of the tibia. The swelling was opened, and the gelatinous contents removed; the abscess cavity cleared out, a drainage-tube introduced, the wound dressed antiseptically, and a splint applied. The tibial cavity did not show signs of closing, so that it was determined to stuff it with decalcified bone. A piece of ox's rib was scraped, decalcified with weak hydrochloric acid, pressed clean, soaked in carbolic solution—one in twenty—for forty-eight hours, and cut in small pieces. The tibia was scraped and gouged to afford free access to the cavity, which was stuffed with the decalcified bone shavings. As these did not entirely fill the cavity, the operator added the pieces of bone that had been removed and kept in borac solution. The cavity was two inches in diameter. It closed very rapidly; but the probe could still enter about an inch, and bare bone could be felt. Several pieces of necrotic bone were removed, being evidently those that had been gouged out and returned at the time of the operation. A very small sinus remained when the patient was discharged, but was soon reported to be closed. Dr. Miller remarks that the closure of the cavity was facilitated by the use of the decalcified bone, as recommended by Senn, and that this was superior to the fresh bone, which was actually a hindrance. The bone cavity quickly filled with granulations, but the external wound remained open till all the necrosed bits of fresh bone came away. There was never a drop of pus, and the temperature never rose over 100° F. The dressing employed was iodoform and wood wool mostly, and all dressing was done under the spray.

The use of the surgical engine would probably greatly facilitate such operations.

TRANSFUSION OF LAMB'S BLOOD IN TYPHOID FEVER.—W. T., who has been seriously ill with typhoid fever for three weeks, had seven continuous hemorrhages from the bowels, the last of which amounted to over a gallon—total loss of blood was near two gallons. These hemorrhages produced such exhaustion as to make it evident that death would soon follow, unless something was done to replace the vital fluid which had been lost.

To meet this emergency, as a last resort I suggested that transfusion of blood be tried, to which the family agreed. Being fully aware that there was no time to lose, I hurriedly sent for Dr. Wilson, of Gastonia, to assist me in the operation. The patient was sinking rapidly. Pulse was almost imperceptible, and respiration very labored. The capillaries of the conjunctiva had become congested, and nervous phenomena were most severe. Immediately upon the arrival of Dr. Wilson the operation was done, using the blood of a lamb, introducing about one quart of arterial blood.

Immediate improvement was noticed. Pulse became stronger, respiration freer and easier, nervous system became quiet, and the patient went off into a quiet and refreshing sleep—the best sleep he had taken since he took his bed. The advent of the lamb's blood into its new habitat has marked a rapid and continuous improvement, and the patient is now able to sit up—sixteen days since the transfusion.

The blood was introduced directly from the common carotid artery into the brachial vein at the bend of the elbow.

I report this case thinking that it would be of practical interest to the profession, and probably the means of saving precious lives.

—Jenkins, *Med. World.*

REICHERT (*Univ. Med. Mag.*) gives a review of those drugs that are believed to conserve the tissues; alcohol, tea, coffee, cocoa, maté, kola, guarana, hemp, tobacco, opium, etc. His conclusions are as follows:

"From these studies it seems clear that the virtues of this remarkable class of substances are due to three chief actions, one or more of which may be characteristic of each member: the production of mental exhilaration, the excitation of the energy-yielding processes, and the ability to furnish energy through their own decomposition. They in common possess the power of causing mental excitement, but which differs greatly in degree, and appreciably in its nature, some of them effecting chiefly the imagination, and others the reasoning faculties. While the condition of the mind is favorable for the manifestation of the peculiar phenomena evinced, and is doubtless the essential factor in the actions of opium and tobacco, it is evidently but secondary with the preparations of alcohol, and with the cocaine and caffeine-bearing substances. Thus the preparations of alcohol also tend to diminish the destruction of the tissues by supplying through their own disintegration the deficit of energy thus resulting, and may enable an enormous increase in the powers of endurance and of the ability for work, even where tissue change is at its normal standard, by supplying from their own potentially laden molecules the excess of energy demanded. On the other hand, those agents which depend upon cocaine or caffeine for their activity, while of themselves incapable of yielding energy, so powerfully excite the energy-yielding processes that the tissues are consumed at a correspondingly quickened pace, and the store of energy proportionately dissipated. Figuratively speaking,

alcohol is fuel added to the fire, and to the extent of the energy which it can yield will save the fuel or add that much energy; but cocaine or caffeine act as a forced draft, supplying no energy in themselves—simply causing the fire to rage more fiercely."

Tabetic Amaurosis.—A girl of eleven years was brought to me recently by her mother, who stated that about three years ago the child complained a great deal of pain in the back of the neck and head, rendered worse by movements. As this gradually disappeared she grew "weak in her legs," and her eye-sight became so bad that she had to leave school. She had always been very lively and mentally bright, and could not be kept in the house, as she sought the company of other children; but the neighbors found fault with the parents for allowing this, as her stumblings and gropings were distressing. The mother said that she had taken the child to several physicians, among whom were the best known "big doctors, who advertised by hand-bills and in the daily papers." One of them pronounced the difficulty to be St. Vitus' dance, and promised to cure it for some outrageous sum in advance. While the occipital and post-cervical pain and rigidity had disappeared, other ailments followed and became steadily worse during the past two years. There was now a constant frontal headache, and at times vertigo and nausea. Her appetite was insatiable, and she was extremely "fidgety." She slept well, had no bowel trouble, nor did she complain of pain aside from headache. There seemed to be but a slight impairment of sensibility upon the left side. Co-ordination was good in the upper extremities, but badly deranged in the lower; in walking the heels struck the ground first, and the gait was tottering, with a little tendency to straddle. Romberg's symptom present but not exaggerated. Tendon reflex absent on left, slightly produced by reinforcing; it exceeded the normal on the right side. The irregularity of her movements was more noticeable when she started to leave her chair; tremors and contortions were then general.

Charcot first described this form of locomotor ataxia, the most striking peculiarities being in the upturned eyes and the vague expression of the face, due to attention not being fixed upon any object. Electrical reactions and sensibility were normal, the latter being slightly greater on the left side, and upon this side the disease was more apparent throughout. The left eye could discern objects only at six inches, the right at about twelve. There was complete iridoplegia; no motions of the dilated pupil could be observed with tests for light and accommodation reactions. Dr. Bettman, at my request, made an ophthalmoscopic examination and found atrophy of both optic discs; the fact of her having any sight at all indicates that this is not complete.

The entire trouble has doubtless arisen from an old unrecognized basilar meningitis with consequent slow involvement of the optic tract and portions of the post-bulbar region. Cardiac crises have not arisen, nor is the hearing implicated, but the vertigo and gastric disturbance and a tenderness on pressure over the cervico-dorsal spine, with the history and rest of the clinical picture, afford a gloomy prognosis. Judicious use of K. I. and ergot may possibly arrest the further course of disease, but it is unlikely, and we are afforded in this case a pitiable instance of a young and promising life cut off through failure to recognize the primary trouble at a time when the most good could have been expected from treatment.

—Clevenger, in *Med. Standard.*

Parasitic Nature of Scurvy.—In my service at the Hospital de la Saude, I received from time to time some cases of scurvy. To clear up the origin of this affection, whose contagious character, sometimes admitted, sometimes contested, caused me to at least suspect the presence of a micro-organism, I have made cultures of the blood, and especially that from the gums, in tubes containing either alkalinized gelatine or the same with gelose. I have repeated these researches upon four patients in whom the affection had reached the maximum of intensity, to the point of producing ecchymoses and leg-ulcers.

Nevertheless, all the tubes remained sterile. In view of this negative result, I concluded that the culture medium chosen was not perhaps the most favorable for the evolution. On the other hand, recollecting that all pathologists mention as one of the determining causes of scurvy the abuse of salt food, I prepared a bouillon composed of gelatine and a saturated solution of marine salt. I have taken from three patients in my charge several drops of blood from the gums, previously washed carefully with bichloride solution, one to one thousand; and with this inoculated the salt bouillon.

At the end of ten days I remarked in the tubes a very slender filament, resembling a shred of mucus, which, beginning at the bottom of the tube, extended to the middle of the bouillon. The gelatine being rendered fluid, by reason of the high surrounding temperature, this filament, after slightly increasing its diameter, fell to the bottom of the tube, where it formed a flaky deposit. By the fifteenth day the gelatine was completely liquefied and turbid. I then proceeded to the microscopic examination (microscope Verick, immersion lens, No. 3 eye-piece, Abbé condenser). Observation made without staining showed numerous colonies of round micrococci, excessively small, isolated, of a diameter less than a demi-thousandth millimetre. Each micrococcus seemed to be surrounded with a soft, transparent material.

These microbes were rapidly stained by fuchsine, after the usual technique, The evolution under the form of mucus filament and the extreme minuteness of each micro-organism characterize sufficiently these cultures.

The subjects which furnished me the blood for the cultures were two children and their mother. Scurvy attacked the mother first, and the two children successively, who slept, ate and drank in common with her.

This was, as it appeared to me, a case of direct contagion, favored by bad hygienic conditions where these people lived, as regarded their dwelling and the nutriment of which they partook. It is probable that the contagious agent was the micro-organism that I have described. To affirm this positively it would be necessary to first reproduce the affection by means of inoculation in receptive animals. My object for the time is only to record the existence of a microbe in the blood of patients affected with scurvy, a microbe developing easily in a nutritive medium saturated with salt.—*Domingos Freire.*

Demonstration of Amœba Coli in Dysentery.—Dr. Lafleur reported a case of dysentery in which the amœba coli had been found in the stools, and exhibited the living parasites under the microscope.

The patient, a man 27 years of age, had been employed as a fireman for a year and a half on the Steamship Karlsruhe, plying between Bremen and Baltimore. He had been in the tropics for a short time in 1880, but not since. While at sea, two

weeks before admission to the hospital, he had slight epistaxis, followed by vomiting and diarrhœa. At the end of a week he was having very numerous bloody stools, accompanied by tenesmus and abdominal pain. On admission to the hospital, May 18, he was much emaciated, weak, with moderate fever and a rapid dicrotic pulse. His stools were greenish-brown, watery, fetid, and contained blood, mucus, much shreddy detritus, and here and there little masses of pus.

On the 19th of May there were found in the stools numerous actively moving amœboid bodies, varying considerably in size, the average being five to seven times the size of a leucocyte. The bodies were of a very pale bluish-green color, and contained from one to many small vacuoles surrounded by fine and often highly refracting granular particles, the whole being invested by a homogeneous outer zone, looking like finely ground glass.

The movements were rapid and flowing in character, the initiative being always taken by the homogeneous outer layer, which was at first slowly projected from some part of the surface as a hemispherical knob, and into which the granular centre of the body then flowed with a sudden, rapid motion. When at rest the bodies usually assumed a circular or oval outline. In some it was possible to make out a circular nucleus. The number of the amœbæ varied greatly with different specimens examined. In some cases as many as eight were seen in one field with a No. 7 Leitz objective. Several stools were examined each day, and in every case actively moving amœbæ were found.

Attention to the following points were found to facilitate the detection of the amœbæ:

1. The stools were passed into a bed-pan previously warmed with hot water.

2. The examination was made immediately, or as soon as possible after the evacuation.

3. Certain portions of the stools were found to contain the amœbæ more uniformly and in greater abundance than others. Small grayish-yellow pus collections, which could easily be picked out with forceps from the brownish fluid part of the stools, always contained amœbæ, often in abundance. In the viscid blood-streaked mucus they were sparingly found, while in the large greenish or yellowish-brown shreddy masses of detritus they were only occasionally seen, and were almost invariably motionless.

A point of special interest was that the case appeared to be one of endemic dysentery, the patient having only once been in the tropics, in 1880, and having enjoyed perfect health until his present illness.

Dr. Welch remarked that this was the second case of dysentery reported on this continent in which amœbæ had been found, the first being that reported by Dr. Osler, in the *Johns Hopkins Hospital Bulletin No. 5*, for May, 1890. The present demonstration of the organism was the first made to a medical society in this country. —*Johns Hopkins Hospital Bulletin.*

KRAUROSIS VULVÆ.—Under this name Smith describes the following case, in the *Buffalo Medical and Surgical Journal*:

Mrs. A., aged fifty-two, married, and the mother of two children, the younger aged sixteen, consulted me in April, 1888. She was of a marked nervous temperament, slight and delicate figure, but apparently in good health. She had never had syphilis nor gonorrhœa. Six years before, and four years prior to the cessation of menstruation, she first noticed a pruritus vulva, attended with pain and scalding upon urination. The pruritus gradually increased for about one year, when she consulted a physician, who found and removed a urethral caruncle. Following the operation there was relief from the pain and scalding upon urination, but no abatement of the pruritus. On consulting a second physician, several months later, she was told that her trouble was undoubtedly the result of diabetes. She was therapeutically and dietetically treated for diabetes for nearly a year, and was given carbolized washes and various ointments for the vulva. The carbolized washes somewhat relieved the pruritus, although it was always present in some degree. This physician made no local examination and never examined the urine for sugar, although he was positive in his diagnosis of diabetes.

I carefully examined several specimens of her urine, obtained at different times, and found no trace of sugar.

On examination of the vulva a most peculiar condition was found. The hairs on the parts were few, harsh and gray. The vulva was slightly gaping. The labia majora were shrunken, inelastic and composed almost entirely of integument, the subcutaneous tissue having nearly disappeared. A little over one-half of the lower or posterior portions of the labia minora were atrophied, while the upper portions were natural in size and appearance, except for the purple spots mentioned below. The vaginal opening was so narrowed that only the small, virgin size of Sims' speculum could be inserted. About one-fourth of an inch below the meatus urinarius was an exquisitely sensitive patch of dark purple color, a little over one-fourth of an inch in width, and extending downward and to the right for about one-half of an inch. Another similar spot, but smaller, was found on the inner or vaginal surface of the upper portion of the left labium minus. Small and exceedingly thin membranous tags were all that remained of the hymen. The clitoris was normal. The integument of the lower portion of the labia minora and on the inner surface of the labia majora was dry, smooth, shining, and bluish-white in color, with here and there a few small thickened spots of a milky-white color. The spots, and the atrophied areas generally, were not so sensitive to pressure as were the red spots. In fact, the kraurotic changes seemed to have been nearly completed in the lower portion of the vulva, while they were still progressing in the upper portion.

The uterus measured a plus two inches in depth. A slight thin discharge escaped from the os. Thinking that the pruritus might possible be caused, or at least aggravated, by the discharge, I inserted into the vagina, or had the patient to do so, twice a day, a dry absorbent cotton tampon to collect the discharge and prevent its escape into the vulva. This was continued for two weeks with no result.

Having, by this time, decided that nearly the whole trouble arose from the two purple spots, I applied to them equal parts of tincture of iodine and carbolic acid. This treatment resulted in a considerable diminution of the pruritus, but did not remove the spots. I then applied pure carbolic acid, which caused excruciating pain, but was, in a short time, followed by complete relief of the pruritus. These applications were continued from time to time, until the spots were entirely destroyed, or at least until they disappeared. Following the disappearance of the spots was a considerable, but not total, relief from the pruritus. Gradually the pruritus grew less and less until it, too, disappeared. In the two years which have elapsed, since the cessation of treatment, there has been no return of the sensitive spots, or of the pruritus.

Medical News and Miscellany.

RUSSIA has 13,000 doctors.

SMALL-POX prevails in Madrid.

CHOLERA has appeared at Massowah.

DIPHTHERIA is prevalent at Oakwood, Ohio.

BAKERS knead their bread by the aid of electric motors.

HICCOUGH may be stopped by nicotine, in doses of $\frac{1}{40}$ grain.

DR. P. S. DONNELLAN will remove, October 1, to 1122 Walnut street.

ELECTRIC incandescent lights are recommended to keep poultices warm.

THE dose of strophanthin is $\frac{1}{300}$ grain. It may be given in distilled water.

THE Jewish Hospital suffered a loss by fire amounting to $700 on September 29.

LATE reports upon salol as a remedy for Asiatic cholera are decidely unfavorable.

DR. L. D. WEBSTER has been lying ill at the house of a relative in Lancaster county.

MANCHESTER inflicts a penalty of $25 on street merchants for continuous shouting.

SCHMELTZ, of Nice, removed a sarcomatous breast during anæsthesia caused by hypnotism.

THE death-rate of St. Paul for August was 9.88 per 1,000; total deaths, 178; births, 269.

THE Bishop of Chester urges the daily opening of churches to secure thorough ventilation.

EDISON is said to be using lithium salts by electrical endosmosis, for the cure of gout, with success.

SAFETY bicycles are said to be more apt to cause hernia than the old-fashioned, break-neck affairs.

DR. LOUIS STARR has returned from Canada and will be at Devon Inn during the month of October.

AN epidemic prevails in the southern suburbs of Berlin, which the physicians believe to be influenza.

PROF. GEORGE STRAWBRIDGE has resigned his chair of Otology in the University of Pennsylvania.

DR. FRANCES DICKINSON has been appointed one of the Lady Managers of the World's Fair in Chicago

THREE deaths from bromic ether are reported from Berlin; where this anesthetic is much used by dentists.

DR. H. A. HARE has removed from 117 South Twenty-second street to 222 South Fifteenth street, Philadelphia.

DR. R. G. PEASE, eighty-seven years old, was found dead in his lodging last week; starvation being the cause.

DR. WALTER M. FRANKLIN, of Lancaster, has been at the Lafayette, accompanied by his friend, J. W. B. Bausman, of the same town. Dr. Franklin was for some time a resident physician at the Pennsylvania Hospital for the Insane, in West Philadelphia.

THE New York Polyclinic has decided to admit to its classes only those holding the diplomas of regular medical colleges.

DR. S. WEIR MITCHELL has been entertaining Mr. and Mrs. Joseph Chamberlain, of England, at his Newport cottage.

THE commander of the Mysore Force has directed that two men in each company shall be instructed in the art of chiropody.

A GRENOBLE druggist was fined one hundred dollars for putting up naphthaline in a prescription that called for beta-naphthol.

A WRITER in the *University Med. Magazine* thinks that phthisis gives a higher mortality rate in narrow streets than in wide ones.

PROF. SAMUEL WOLFE gave the opening address at the Medico-Chirurgical College, October 1. A large audience was present.

QUEBEC has offered one hundred acres of land to every father of twelve or more living children, and 1,250 claims have been filed.

THE Medico-Chirurgical Hospital has opened an Annex at Seventeenth and Summer streets, while the main hospital is being rebuilt.

A YOUNG lady in London is said to have been fatally poisoned by drinking sherbet; the syrup being colored red with aniline containing arsenic.

DR. PEARSON SERRILL, of Gordon, was summoned to Shoemakerville to attend the victims of the railroad accident in which Dr. Vanderslice lost his life.

THE address of the *Pacific Medical Journal* (successor to the *Pacific Medical and Surgical Journal and Western Lancet*) is now 720 Broadway, San Francisco, Cal.

ABADIE uses the galvano-cautery in purulent ophthalmia, when ulceration with destruction of corneal tissue has occurred and the case is considered desperate.

GEORGE S. HULL reports a case of noma, or gangrene of the cheek, following pneumonia, in a child eight years old. Recovery ensued, with great deformity.

BRITISH COLUMBIA compels British and Canadian graduates to pass an examination and pay a fee of $100, before they are allowed to practice in that province.

DR. A. VICTORIA SCOTT, Vice-President of the National Woman's Health Association, lectured on Tyrotoxicon, Monday evening, last week, at 1229 Chestnut street.

DR. THOMAS FELL, of Annapolis, Maryland, has been chosen a delegate to the General Convention of the Brotherhood of St. Andrew, which meets in this city this month.

THE Mission Hospital at Pekin treated nearly 20,000 cases last year. Among the curiosities was a youth who cut off a piece of his calf to make soup for his sick father.

RUSSIAN baths are recommended by a sufferer from rheumatism. "After several trials, one should take the steam as hot as he can bear it on the affected part of his body."

DR. JOHN H. B. AMICK, lately appointed by President Harrison, and confirmed by the Senate, as Drug Examiner to succeed Dr. Laughlin, was sworn in last Monday week.

DR. WILLIAM PEPPER spoke last week at Association Hall on "The Importance of Health and How to Preserve It." This was the first of the series of lectures on "Health Talks."

DR. T. RIDGWAY BARKER, one of the most popular young physicians connected with the Medico-Chirurgical College, was married to Miss Mary Gumbes, at St. Andrew's Church, last Wednesday week.

W. H. SCHIEFFELIN & Co.'s pil. phenacetine et caffein. citrat. composed of phenacetine-Bayer, 3 gr.; caffeinæ citrat., 1½ grains, is especially desirable to use in cases of migraine and nervous headaches.

VISITORS to the late Congress can be distinguished from ordinary doctors by the fierce Bismarckian cut of their beard, and the commanding manner with which they pronounce the words "Zwei lager!"

DR. HAMMOND says that thin soles are the worst propagators of disease amongst women. Why don't he go further, and state what are proper gaiters?
—*New York News.*

THE report has been made and denied that Sister Rose Gertrude is going to marry Dr. Lutz, at Molokai. It is to be hoped that the report is true; and that this noble woman will transmit her heroism to numerous descendants.

THE Brazilian army medical corps consists of two hundred men, whose rank is graded from that of general down to lieutenant. The pharmaceutical corps contains eighty-five, from lieutenant-colonel down to sub-lieutenant.

THE antiseptic artificial tympanic membranes invented by Dr. Cousins, and described some time since in this journal, can be procured from the American agents, Messrs. Fairchild Bros. & Foster, 96 Maiden Lane, New York City.

THE *Lancet* reports the poisoning of over one hundred men at a "free tea." The viands consisted of boiled beef, ham and tea, and the toxic agent is supposed to have been a ptomaine in the beef; which is said to have been tainted.

THE pig-headedness of the old army officers who oppose the giving of due credit to the medical corps can hardly resist such figures as these: In the Lushai expedition, 9 persons were killed in action, 207 died of diseases, and 2,122 were invalided.

THE recent graduate looks down from his lofty height upon his preceptor, whom he denominates an old fogy. Each "tough" case, however, lessens the youngster's self-esteem and increases his respect for his senior; until in a few years he begins to wish he knew a quarter as much.

W. B. JENNINGS, of Marshall, Texas, has discovered a very effective and simple means of getting rid of roaches. It is simply to put a toad in any room infested with them. Last summer a large toad got into the post-office and remained there over night. Afterward the office was clear of roaches until a few weeks since, when they reappeared. Another toad was placed in the room and the roaches again disappeared.

WHILE Italy leads in the revival of cremation, she has an unusual need for it, as her burial arrangements have been defective. In 1885, out of her 8,258 communes, 120 had no burial places; in 274 the dead were interred in churches, and in 628 the bodies were thrown into a common pit.

DURING August St. Louis buried 710 of her citizens. The principal incentives were: Diarrhœa, 74; phthisis, 70; marasmus, 46; convulsions, 42; inanition, 37; old age, 32; pneumonia, 28; Bright's, 21; malaria, 26; typhoid, 19; diphtheria, 15. The births during August numbered 990.

DURING the eight years ending with 1888, there were in Prussia 289 suicides of school children. Forty-nine of these were girls. The causes assigned were: Fear of punishment, 80; mental disease, 26; morbid ambition, 19; fear of examination, 16; practical joking, 7; disappointed love, 5.

ETHER drinking is said to have arisen in Ulster during Father Matthew's visits. Those who had taken the pledge found that, without breaking it in letter, they could get drunk on ether. Methyl ether can be had at any time, and the quantity needed, a half ounce, costs only one cent.

ARMOUR appears to be on bad terms with the rumor committee. It has been alleged that the flesh of diseased animals is exported; that of healthy cattle being reserved for home use. This is too wildly improbable to require denial. Much more likely that the diseased meat is reserved for home consumption.

DR. SCHWENINGER, Bismarck's physician, has been compelled to give up all his professional work, owing to over-exertion and the spending of two nights out of every three on railroad cars. The advice he would have been sure to give one of his patients, under such circumstances, he failed to apply in his own case.

IT is said that while 43,000 pilgrims to Mecca arrived at the Red Sea ports, all provided with return tickets, but 28,000 will avail themselves of them. The other 15,000 have died of cholera. Of pilgrims coming by land no account can be kept; but one caravan of 2,500 is said to have been reduced to 900 when it reached Mecca.

A NEWCASTLE woman had a "wen" on her neck; for which a "wise woman" advised her to go alone and lay all night in an outhouse with the hand of a corpse on the wen, as an infallible cure. She did so; and the shock was so great that she did not rally for months, but finally died of the wen. The corpse was that of a suicide.

THE College of Physicians and Surgeons in Chicago opened its winter term, September 23. Addresses were given by S. A. McWilliams and Prof. Silva. The speakers referred to the loss the college had sustained in the death of Prof. R. W. Jones, a short time since. The class promises to largely exceed that of last winter.

AT a meeting of the Philadelphia County Medical Society, last Thursday week, at Thirteenth and Locust streets, Dr. Joseph Tunis, by invitation of the Board of Directors, read a paper, entitled Rib Fracture from Muscular Action, with a Report of Forty-two Collected Cases. Dr. Joseph Price also read a paper on the subject of Certain Causes of Major Pelvic Troubles Traceable to Minor Gynecology.

Everybody knows that the Standard Oil Company has amassed an almost incredible amount by the most gigantic and selfish monopoly of modern times. And yet when its President, Mr. Rockafeller, gives back to the country a trifle in the shape of an endowment to a University, he is lauded as a benefactor. This world is a paltry affair, after all.

Dr. George W. Grimm, Health Officer of Buffalo, was in the city, seeking information of the Health Board system here, last Tuesday week. He was taken in charge by President Ford, who explained to him the system used in this city. Dr. Grimm has been to Boston, New York and Baltimore, and spent a few days here before returning home.

Ground was broken at the Philadelphia Hospital for the new museum, which adjoints the dead-house. The new building will be forty feet by forty feet, and sixteen feet high. The light will come from the roof, and so arranged as to give the fullest light for examinations. The cost will be $2,500, and the museum will be under the charge of Dr. Formad.

Dr. Mary Fisher has not become Resident Physician at St. Clement's Hospital, but is on the medical staff as Attending Physician; a place she has occupied for over a year. She has been compelled to resign her position in the Normal School on account of the demands of her large and increasing practice. *New England Medical Monthly* please copy.

Dr. B. W. Richardson protests in an exchange against the proposed use of the lethal chamber in capital cases, on the ground that it would be a degradation of science; and there are those who will be uncharitable enough to think he wants the profession to run the dispatching process itself at so much per visit. This is a little fee-bill, but it will have to go.

Duboisia Hopwoodii, an Australian shrub, is proposed as a substitute for tobacco. It is said that the leaves contain an alkaloid identical with nicotine. If so, it is not at first sight easy to see what is gained by the substitution. If duboisia were to be substituted for cabbage, burdock, old gum shoes, oakum, and the other material used in the manufacture of cigarettes, a decided benefit might result.

Efforts are being made in India to raise the "age of consent" to twelve years; not that this is the proper age at which to begin sexual relations, but as an improvement on the present custom. In a late number of the *Indian Medical Gazette* we note a case in which a Hindoo "child wife," a mere undeveloped infant, died from the effects of injury received from her husband's efforts at sexual intercourse.

The following extract is from Mrs. Cox's report on the Pine Ridge Indian Agency: "There is one thing much needed on the reservation—that is a hospital. The sick have no chance of recovery, having no care; their medicine man is sent for, and he puts charms on them and says some chants, then demands a pony for payment of his services. In all our missionary efforts now the hospital is considered the strongest agency of civilization; there should be no delay in having them established."

Swindling his Fellow Doctors.—Dr. W. W. Dyson, a young man, had a hearing before Magistrate Pole at City Hall, on the charge of larceny and false pretence.

Dr. L. G. Hammond, of 712 South Tenth street, said the defendant obtained his hypodermic syringe on the representation that he was treating a case of angina pectoris in the neighborhood and had left his own syringe at home. He did not return it.

Dr. A. L. Rainear, of 2026 Diamond street, said he loaned Dyson a copy of Da Costa's Diagnosis, valued at $6.50, in July last, for a few days. Dyson said he wished to consult it to obtain information on a paper which he was writing. They had been classmates. He loaned the book, telling Dyson to return it within forty-eight hours; but he had not sent it back yet. The defendant claimed that he had sent Dr. Hammond's syringe home by a colored man. He was put under eight hundred dollars bail.

We have spoken of the disposition exhibited by some foreign journals to treat American books with undue severity. It gives us pleasure to note an instance of a very different spirit, and to call attention to a British compliment to a deserving American work. In reviewing Gould's Dictionary, the *British Medical Journal* says: "In fact, taking cheapness and handiness into account, we certainly think this the general practitioner's model dictionary, and cordially recommend it to our readers."

The State Board of Medical Examiners of New Jersey will meet in the Senate Chamber at the Capitol in Trenton, Thursday, October 9, at 9 o'clock in the morning, for the purpose of examining candidates presenting themselves for a license to practice medicine in that State. Under the present medical law of that State every person desiring to practice medicine or surgery, in any of its branches or in any way, who was not legally registered previous to July 4, 1890, must first obtain a license from this Board.

A Physical Training School and Gymnasium for Women and Children has been opened at 1808 Green street, with Dr. James Farrar Stone as Director. The growing popularity of physical training, as a means of strengthening the system and developing the frame, is a hopeful sign of the times. As the benefits of sanitation, in its widest sense, become known to the inner consciousness of man, sickness "by mysterious dispensation of Providence," and the consequent drugging, will become matters of ancient history.

It is proposed to pass a law in Russia providing that every factory which is eight versts distant from a city shall maintain a hospital with from ten to forty beds, according to the number of laborers it employs. It must also have a drug store, and keep a licensed druggist and physician constantly on the premises. A circuit physician, appointed by the Government, must regularly pay visits to such factory hospitals, and see to it that the drug stores be properly fitted out, and that the resident pharmacists and physicians be on their respective posts.

An Opportunity.—A cash prize of one thousand dollars has been offered for the best short story or novel, having the Grandfather Mountain and the beautiful scenery of that locality woven into the plot.

This mountain, situated as it is in the most picturesque part of Western North Carolina, furnishes an attractive setting for an interesting story.

The selection will be made by a committee of competent reviewers, and the story must not be less than ten nor exceed fifty pages.

Detailed information may be obtained of the Linville Improvement Company, of Linville, North Carolina.

THE Harlem Medical Association held its first regular meeting on Wednesday, October 1, at 5 West 125th street. Papers were presented by Drs. Richard, Truax, Manley, Santvoord, and Fridenberg. The following are the officers for the ensuing year: President, Dr. E. Fridenberg; Vice-President, Dr. M. C. O'Brien; Treasurer, Dr. D. Franklin; Secretary, Dr. A. H. Leary; Trustees, Dr. S. E. Gibbs, Dr. M. R. Richard, Dr. R. Van Santvoord; Committee on New Members, Dr. G. H. Cocks, Dr. M. R. Richard; Committee on Publication, Dr. T. H. Manley, Dr. A. H. Leary.

NEW PATENTS, ETC:—

PATENTS ISSUED SEPTEMBER 23, 1890.

Inhaler	F. W. Wiesebrock	New York, N. Y.
Insecticide	Farwell & Rhines	Watertown, N. Y.
Uterine supporter, A.	A. T. Sherwood	San Francisco, Cal.
Hypodermic syringe	Fergen & MacPhinnie	Chicago, Ill.

TRADE-MARKS ISSUED SEPTEMBER 23, 1890.

Herb remedies for certain chronic diseases. (The figure of a Chinaman, clothed in Chinese garb, sitting in a chair, with a fan in his right hand, a cap on his head, and wearing spectacles)	G. C. Cooper	Detroit, Mich.
Remedy for blood and kidney diseases. (The portrait of the registrant, "Samuel P. Hite.")	S. P. Hite	Staunton Va.

LABEL ISSUED SEPTEMBER 23, 1890.

"Ferro-manganese water"	Excelsior Springs Co.	Kansas City, Mo.

PATENTS LAPSING SEPTEMBER 23, 1890.

Medical compound, or opium-cure	U. H. Kellogg	Jamestown, N. Y.
Sulphuric acid manufacture	Thomson & Greene	Philadelphia, Pa.

BOARD OF HEALTH.—At the last meeting of the Board of Health Chief Inspector Kennedy made a report concerning his inspection of the Alaska District. The number of houses inspected was 2,770, containing a population of 16,734 persons; 424 houses contained nuisances, which were ordered abated. The character and habits of a large number of the residents were such as to make it almost impossible to keep the district clean. A reckless disregard of cleanliness was the rule, particularly among the Italians and Russians. In the Italian quarter persons of all ages were crowded together, a family occupying one room, perhaps 12 by 14 feet. The number of vaccinations reported was 16,395; persons reported sick, less than 100. Number of typhoid cases from January 31 to July 31, 16; scarlet fever cases, 9.

A resolution was adopted ordering the Port Physician to detain all vessels from Spain and Japan, and hold them in the stream until instructed by the Board as to their disposition.

RESUME OF MEDICAL PRACTICE ACTS IN THE DIFFERENT STATES.

Alabama.—Examination and endorsement of diploma by a County Medical Society. Violation of law, $100 fine. Passed Feb. 9, 1887.

Arizona.—Register diploma with county recorder. No examination.

Arkansas.—Five years' practice in State. Registration of diploma, or examination by State Board of Examiners.

California.—Registration of diploma after endorsement by the State Board of either of the schools. After 1890–91 three sessions of six months each in separate years.

Colorado.—Endorsement of diploma or examination by State Board of Examiners. After July 1, 1893, three years' study, including three sessions of at least twenty weeks each in different college years.

Connecticut.—No law, except against advertising itinerant physicians.

Dakota.—Endorsement of diploma or examination by board. After 1891, three sessions required.

Delaware.—Eight years' practice in State. Registration, and license by county clerk.

District of Columbia —Endorsement of diploma or examination by State Medical Board.

Florida.—Endorsement of diploma or examination by either State Board of Examiners. The Homœopathic Board, which meets semi-annually, will endorse Eclectic diplomas.

Georgia.—Register diploma before Clerk of Superior Court.

Idaho.—Record diploma at county seat.

Illinois.—Endorsement of diploma for registration, or examination by State Board. Preliminary entrance examination required, or equivalent. After 1890–91, four years' study and three sesions of at least twenty weeks each.

Indiana.—Registration of diploma before county clerk.

Indian Territory.—Examination or registration before different boards in each Indian nation.

Iowa.—Endorsement of diploma or examination and registration by State Board of Medical Examiners. After 1890–91, four years' reading and three sessions of six months each in different years.

Kansas.—Certificate issued by either of the three State societies.

Kentucky.—Registration and endorsement of diploma by Secretary of State Board of Health, or ten years' practice.

Louisiana.—Recording diploma before county clerk or justice of the peace after endorsement of same by State Board, which is "required to certify to the diploma of any medical institution of credit and respectability without regard to its system of therapeutics."

Maine.—No law.

Maryland.—Certificates issued by State Board of Health and recorded.

Massachusetts.—No law.

Michigan.—Record diploma with county clerk.

Minnesota.—Examination by State Board of Examiners without regard to diploma. Certificate of three sessions college attendance required.

Mississippi.—Examination by a County Board of Medical Censors.

Missouri.—Registration after examination or endorsement of diploma by State Board of Medical Examiners.

Montana.—Ten years' practice, or endorsement and registration of diploma, or examination by State Board. Three sessions of at least four months now required.

Nebraska.—Registration before county clerk.

Nevada.—Registration of diploma before county recorder. Penalty $500 for violation.

New Hampshire.—Board of Censors of each medical society can issue licenses.

New Jersey.—Record a copy of diploma from a "legally chartered medical college of any State" with county recorder.

New York.—Endorsement of diploma for registration by any college within the State. Students who began study of medicine after June, 1889, must have certificate of regular preliminary qualifications, and pass examination before either of the three State Boards, in addition to attendance upon a college requiring at least three sessions.

North Carolina —Examination by State Board.

Ohio.—No law enforced, except the one prohibiting any physician from suing patients for service unless he holds a diploma.

Oregon.—Registration after endorsement or examination by State Board of Examiners.

Pennsylvania. — Registration of diploma before county prothonotary after endorsement by some medical college within the State. College allowed to charge a fee of $25 for examination.

Rhode Island.—No law.

South Carolina.—Endorsement of diploma or examination by a college within the State, or State Board of Medical Examiners.

Tennessee.—Registration after endorsement of diploma, or examination by State Board.

Texas.—Registration after endorsement of diploma, or examination by a District Board of Examiners.

Vermont.—Registration after endorsement of diploma, or examination by a Board of Medical Censors appointed by either State Medical Society.

Virginia.—Examination only by State or District Examining Boards.

Washington.—Examination or endorsement of diploma by State Medical Board.

West Virginia.—Registration after endorsement by the State Board of Health.

Wisconsin.—Examination or endorsement of diploma by any State or county society.

—*Eclectic Med. Journal.*

THE NEW JERSEY LAW.—

An Act to regulate the Practice of Medicine and Surgery, to license Physicians and Surgeons, and to punish persons violating the provisions thereof.

1. Be it enacted by the Senate and General Assembly of the State of New Jersey, That the Governor shall appoint a Board of Examiners, to be known as the State Board of Medical Examiners; said board shall consist of nine members; the appointees shall be persons of recognized professional ability and honor; the terms of office of said board shall be three years, or until their successors are appointed; provided, however, that the members of the board first appointed shall be divided into three classes, each class to consist of three persons; the first class shall hold office under said appointment for one year, the second for two years, and the third for three years from the date of their appointment, and thereafter each member of said board shall be appointed for a term of three years; and provided further, that said board shall consist of five old school, three homœopaths and one eclectic; it is further provided, that no member of said board shall serve more than two terms in succession; no member of any college or university having a medical department shall be appointed to serve as a member of said board.

2. And be it enacted, That said Board of Medical Examiners shall elect a president, a secretary, and a treasurer; it shall have a common seal, and the president shall be empowered to administer oaths in taking testimony upon any matter pertaining to the duties of said board; said board shall hold meetings for examinations at the capitol building of this State, the second Thursday of January, April, July and October of each year, and at such other times and places as the board shall deem expedient; said board shall keep an official record of all its meetings, also an official register of all applicants for examination for a license to practice medicine and surgery in this State; said register for license shall show the name, age, and last place of residence of each candidate, the time he or she has spent in medical study, in or out of medical school, and the names and locations of all medical schools which have granted said applicant any degree or certificate of attendance upon lectures in medicine; said register shall also show whether such applicant was rejected or licensed under this act; said register shall be *prima facie* evidence of all matters therein contained.

3. And be it enacted, That all persons hereafter commencing the practice of medicine or surgery, in any of its branches in this State, shall apply to said Board of Medical Examiners for a license so to do; applicants for examination shall be divided into three classes, to wit: first, persons graduated from a legally chartered medical school not less than five years before the date of application for a license; second, all other persons graduated from a legally chartered medical school; and third, medical students taking a regular course of medical instruction; applicants of the first class shall submit to examination upon the following named branches, to wit: materia medica and therapeutics, obstretics and gynecology, practice of medicine, surgery and surgical anatomy; those of the second and third class shall submit to examination upon anatomy, physiology, chemistry, pathology, materia medica and therapeutics, histology, hygiene, practice of medicine, surgery, obstetrics, and gynecology diseases of the eye and ear, medical jurisprudence and such other branches as the board may deem advisable; the question for examination of applicants of the first and second classes shall be the same in branches common to both; said board shall not license applicants of the second and third classes after January first, one thousand eight hundred and ninety-two, until satisfactory proof is furnished that the applicant has studied medicine and surgery three years, is of good moral character, and over twenty-one years of age; applicants of the third class, after they shall have studied medicine and surgery at least two years, can be examined upon the following named branches, to wit: anatomy, physiology, chemistry, histology and pathology, materia medica and therapeutics; if said examination is satisfactory to all the members of said board, it may issue a certificate that

the applicant has passed a final examination in these branches, and such certificate, if presented by the applicant when he or she shall make the application for license to practice, shall be accepted by said board in lieu of an examination in those branches; all examination shall be both scientific and practical, but of sufficient severity to test the candidates' fitness to practice medicine and surgery.

4. And be it enacted, That all examinations shall be in writing; in all examinations the questions and answers must be, except in materia medica and therapeutics such as can be answered in common by all schools of practice; and if the applicant intends to practice homœopathy or eclectism the member or members of said board of those schools shall examine said applicant in materia medica and therapeutics; if said examination is satisfactory, the board shall issue a license entitling the applicant to practice medicine in this State; the votes of all examiners shall be by yes or no, and written, with their signatures, upon the backs of the examination papers of each candidate for the respective branches; a license shall not be issue in any case unless the applicant passes an examination satisfactory to all the members of said board; said examination papers shall be kept on file by the secretary of said board, and shall be *prima facie* evidence of all matters therein contained; any applicant refused a license by said board for failure on examination may appeal from the decision of said board to the appointing power thereof, who may thereupon appoint a medical committee of review consisting of three members, one from each school of medicine, who shall examine the examination papers of the said applicant, and from them determine whether a license should issue, and their decision shall be final; if said commission by an unanimous vote reverse the determination of the board, the board shall thereupon issue a license to the applicant, the expense of said appeal shall be borne by the applicant; all licenses shall be signed by the president and secretary of said board, and shall be attested by the seal thereof; the fee for examination shall be fifteen dollars for each applicant of the first and second classes, and twenty dollars for each applicant of the third class; it shall be paid to the treasurer of the board and applied toward defraying the expenses thereof.

5. And be it enacted, That the board may, by a unanimous vote, refuse to grant, or may revoke a license for the following causes, to wit: chronic and persistent inebriety, the practice of criminal abortion, conviction of crime involving moral turpitude, or for publicly advertising special ability to treat or cure diseases which, in the opinion of said board, it is impossible to cure; in complaints for violating the provisions of this section, the accused person shall be furnished with a copy of the complaint, and given a hearing before said board in person, or by attorney.

6. And be it enacted, That the person so receiving said license shall file the same, or a certified copy thereof, with the clerk of the county in which he or she resides, and said clerk shall file said certificate, or copy thereof, and enter a memorandum thereof, giving the date of said license, and the name of the person to whom the same is issued, and the date of said filing, in a book to be provided and kept for that purpose; and for which registry the said county clerk shall be entitled to demand and receive from each person registering the sum of fifty cents; in case a person so licensed shall so move into another county of this State, he or she shall procure from the said clerk a certified copy of said license, and then file the same with the clerk in the county to which he or she shall remove; said clerk shall file and enter the same with like effect as if the same was the original license, and for which registry the said county clerk shall be entitled to demand and receive the sum of fifty cents.

7. And be it enacted, That this act shall not apply to the commissioned surgeons of the United States army, navy or marine hospital service, or to regularly licensed physicians or surgeons in actual consultation from other States or Territories, or to regularly licensed physicians or surgeons actually called from other States or Territories to attend cases in this State, or to any person now entitled to practice medicine in this State.

8. And be it enacted, That any person shall be regarded as practising medicine or surgery, within the meaning of this act, who shall append the letters M.D. or M.B. to his or her name, or prescribe, for the use of any person or persons, any drug, or medicine, or other agency for the treatment, cure, or relief of any bodily injury, infirmity, or disease; this act shall not apply to dentists in the legitimate practice of their profession.

9. And be it enacted, That any person hereafter commencing the practice of medicine or surgery in this State without first having obtained the license herein provided for, or contrary to the provisions of this act, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not less than fifty dollars or more than one hundred dollars, or by imprisonment in the county jail for a period of not less than ten or more than ninety days, or both fine and imprisonment; it shall be the duty of the respective county attorneys to prosecute violations of the provisions of this act.

10. And be it enacted, That the expenses of said board and of the examinations shall be paid from the license fees above provided for, and if any surplus remain, the same may be distributed among the members of said board as a compensation for their services as members, but otherwise shall receive no compensation whatever.

11. And be it enacted, That all acts or parts of acts, general or special, now existing, not in accordance with the provisions of this act or inconsistent therewith, are hereby repealed.

Approved May 12, 1890.

Regulations for conducting examinations.—1. Each candidate shall present certificates of age, moral character, preliminary education, and time and place of medical studies. Each of these certificates shall be accompanied by an affidavit if the board so directs.

2. All examinations shall be in writing (with ink) upon paper furnished by the Secretary.

As many candidates may be examined at each session as circumstances will permit, making each section as large as convenient.

3. The examinations shall continue two days; the sessions of the first day being from 9-11, 11-1, 2-4, 4-6 and 8-10 respectively; the sessions of the second day being from 9-11, 11-1, 2-4 and 4-6 respectively. The final meeting for the adjudication of the results of the examinations shall be held at 8 o'clock in the evening of the second day.

4. The Examiner in each branch shall not be engaged in any other business except supervising the examination while it is going on, and there shall be one or more associate Examiners present with him during the entire session.

5. A total average of 75 per cent. shall be necessary to license a candidate, providing that in no one branch shall the average percentage be less than 33⅓ per

cent., in which case, however, should the total average percentage in all the other branches be above 75 per cent., the candidate may be granted a second examination immediately upon that branch.

6. Each candidate shall sign a pledge that he has neither given nor received any information concerning the examination, or used in any way unfair means during the same.

This pledge, with the real name and number in a sealed envelope, with the number upon it, together with the examination paper, which shall be signed only with the number, shall be given to the Secretary immediately after the conclusion of the examination.

The same number shall be used by a candidate during the whole series of his examinations.

7. Any candidate found guilty of violating his pledge, in giving or receiving information, shall be adjudged guilty of grossly immoral conduct, and shall be rejected.

8. No fee will be returned to a candidate after he has commenced his examination. A rejected candidate can be re-examined within one year without an additional fee.

9. These regulations may be amended by a two-thirds vote of the Board; said amendment having been read at a previous meeting, and being spread in full upon the call for the meeting at which action thereon is to be taken.

Adopted September 18, 1890.

Sections.—1. Materia Medica and Therapeutics. 2. Obstetrics and Gynecology. 3. Practice of Medicine. 4. Surgery (and Surgical Anatomy). 5. Anatomy. 6. Physiology. 7. Chemistry. 8. Histology, Pathology, and Diseases of the Eye and Ear. 9. Hygiene and Medical Jurisprudence.

Members, 1890–91.—H. C. Hendry, M.D., Newark; Henry G. Wagoner, M.D., Somerville; A. H. Worthington, M.D., Trenton; William L. Newell, M.D., Millville; Eugene Tiesler, M.D., Orange; Wm. Perry Watson, M.D., Jersey City; D. R. Atwell, M.D., Hoboken; Geo. W. Brown, M.D., Long Branch; Armin Eubelacker, M.D., Morristown.

Officers, 1890–91.—W. L. Newell, M. D., President; Wm. Perry Watson, M.D., Secretary; A. H. Worthington, M. D., Treasurer.

Organized September 2, 1890.

TO CONTRIBUTORS AND CORRSEPONDENTS.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from September 12, 1890, to September 29, 1890.

By direction of the Acting Secretary of War, the following changes in the stations of officers of the Medical Department are ordered: Captain William G. Spencer, Assistant-Surgeon, will, upon the abandonment of Fort Bridger, Wyoming (his present station), report in person to the commanding officer of Fort Omaha, Nebraska, for duty at that station, relieving First Lieutenant Alfred E. Bradley, Assistant-Surgeon. Lieutenant Bradley, upon being relieved by Captain Spencer, will report in person to the commanding general, Department of the Platte, for duty as Attending Surgeon at the headquarters of that Department. S. O. 214, par. 16, A. G. O., Washington, D. C., September 12, 1890.

Middleton, Johnson V. D., Major and Surgeon, is relieved from duty at David's Island, New York, and will report in person to the commanding officer, Fort Columbus, New York City, for duty at that station, relieving Major Joseph R. Gibson, Surgeon, and reporting by letter to the commanding general, Division of the Atlantic. Major Gibson, on being relieved by Major Middleton, will report in person to the commanding officer, David's Island, New York, for duty at that station, and by letter to the superintendent of the recruiting service. Par. 1, S. O. 219, A. G. O., Washington, September 18, 1890.

Under the provisions of General Orders No. 43, c. s., Headquarters of the Army, Adjutant-General's Office, the post of Little Rock Barracks, Arkansas, will be abandoned, to take effect not later than October 1, 1890. Captain Paul R. Brown, Assistant-Surgeon, will accompany Company E to Fort Supply, Indian Territory, and there take station until further orders. G. O. 15, Headquarters Department of the Missouri, St. Louis, Mo., August 11, 1890.

The leave of absence for seven days granted Captain Aaron H. Appel, Assistant-Surgeon, by the commanding officer of Fort D. A. Russell, Wyo., is extended twenty-three days. S. O. 70, par 3, Department of the Platte, September 17, 1890.

Leave of absence for one month, to take effect the 1st proximo, is granted Captain C. B. Ewing, Assistant-Surgeon. S. O. 131, par. 5, Department of the Missouri, September 22, 1890.

Leave of absence for twenty days, to take effect when his services can be spared by his post commander, is granted Captain Louis S. Tesson, Assistant-Surgeon, Fort Sidney, Nebraska. S. O. 72, Department of the Platte, Omaha, Neb., September 25, 1890.

Changes in the Medical Corps of the U. S. Navy for the two weeks ending September 20, 1890.

Woolverton, Theoron, Medical Director. Ordered to the U. S. S. "Philadelphia."

Penrose, Thomas N., Medical Inspector. Detached from the U. S. S. "Richmond."

Gardner, J. E., Passed Assistant-Surgeon. Detached from the U. S. F. C. Str. "Albatross."

Drake, N. H., Passed Assistant-Surgeon. Detached from the U. S. C. S. Str. "McArthur," and to the U. S. F. C. Str. "Albatross."

Berryhill, T. A., Passed Assistant-Surgeon. Detached from the Hospital, Mare Island, California, and to the U. S. C. S. Str. "McArthur."

Heffinger, A. C., Passed Assistant-Surgeon. Ordered before Retiring Board, October 1, 1890.

Olcott, F. W., Passed Assistant-Surgeon. Ordered to the U. S. S. "Alert."

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service from August 12, 1890, to September 6, 1890,

Vansant, John, Surgeon. Granted leave of absence for thirty days, to take effect upon return of Assistant-Surgeon J. C. Perry to duty. September 5, 1890.

Wyman, Walter, Surgeon. To proceed to Cape Charles Quarantine Station on special duty. August 25, 1890.

Stoner, Geo. W., Surgeon. Granted leave of absence for four days. August 19, 1890.

Carmichael, D. A., Passed Assistant-Surgeon. Leave of absence extended fifteen days. August 26, 1890.

Ames, R. P. M., Passed Assistant-Surgeon. To proceed to Memphis, Tenn., on temporary duty.

Devan, S. C., Passed Assistant-Surgeon. Leave extended five days, on account of sickness. August 12, 1890.

Williams, L. L., Passed Assistant-Surgeon. Granted leave of absence for thirty days. September 5, 1890.

Goodwin, H. F., Assistant-Surgeon. Granted leave of absence for thirty days. August 21, 1890.

Cobb, J. O., Assistant-Surgeon. To proceed to Marine Hospital, Detroit, Mich., for duty. August 16, 1890.

Hussey, S. H., Assistant-Surgeon. Granted leave of absence for thirty days. August 19, 1890.

Perry, J. C., Assistant-Surgeon. Granted leave of absence for twenty days, to take effect when relieved. September 3, 1890.

Young, G. B., Assistant-Surgeon. To rejoin his station at St. Louis, Mo., when relieved. September 3, 1890.

Appointment.

Rosenau, Milton J., Assistant-Surgeon. Commissioned as an Assistant-Surgeon by the President, August 25, 1890. Ordered to Chicago, Ill., for temporary duty. August 27, 1890.

The Times and Register.

Vol. XXI, No. 15. NEW YORK AND PHILADELPHIA, OCTOBER 11, 1890. Whole No. 631.

Address.

CHICAGO ACADEMY OF MEDICINE.[1]

By S. V. CLEVENGER, M.D.

AUGUST 2, the incorporation of this Academy was effected; the official papers being sent by the Secretary of State. We meet to-day to proceed with the organization; to frame a constitution and by-laws, and to begin in earnest scientific work, creditable to the institution and its members.

An official physician is accredited with the remark that medicine could only be cultivated in the East, as the West and South were too malarial to permit science to be developed successfully. The only malaria that has, in my experience, interfered with the progress of medicine, is political, and its debilitating influence is universal. Both "malaria" and politics are rampant on parts of the Potomac river.

We have long understood that there was a necessity for a purely medical society in our midst, wherein medical topics alone would occupy the attention of physicians to the exclusion of clique interests, politics, and other distracting, degrading matters, but how to institute such an organization has been, and is, a problem, and while we may congratulate ourselves upon having begun its solution, we must remember that in common with everything human, we are fallible, and we may reach a far different result from the one desired, through an apparently insignificant flaw in the initiatory process.

The avowed object of the academy is "for the encouragement of pure and applied medical science." Inasmuch as political, social and clique intriguery is directly hostile to such encouragement, it will not be possible to accomplish even mediocre scientific work unless these enemies are forbidden entrance. With human nature as it is, resolutions are easier made than kept.

We start out with the hope, the determination to elevate medicine, to make it more scientific, to encourage research, to spread a knowledge of what has been done, and to stimulate workers to renewed and better effort.

Forecasts can only be made upon retrospects; the history of the past alone enables the statesman to advise his nation for the future; even the savage recognizes the advisability of having "old men for counsel and young men for action;" for impetuosity, in howsoever good a cause, may ruin instead of accomplish. It is best, therefore, that we should look at our environment carefully, and, as far as possible, seek out the causes of failure in other organizations.

The scientific medical man is usually poor in purse, and his studies naturally keep him out of money-making avenues, make him poorer, obscure, unknown. He visits his local medical society with the desire to learn and to impart information that has cost him dearly to acquire. He soon realizes that things are far from being what they should be. At annual elections two or three cliques fight for the offices, and do not hesitate to resort to the methods of the ordinary politician to secure such places; wrangles over ethical points, packed meetings to defeat some needed reform in our public hospitals or asylums are occasionally too frequent, and the reading of sensational papers with a full attendance of newspaper reporters, and innumerable other schemes of the kind, prostitute the society into an assemblage of wire pullers, hypocrites and tenth rate medical essayists, crowding the quiet, studious seeker after learning out the door.

All over this great country this is the common experience; resulting in the foisting upon the ignorant public of blatant quacks, and the final extinction of even the desire to make things better, for the battle is to the strong sneak; and the weak, the scientist, goes to the wall. Man was undoubtedly evolved from quadrupedal ancestry, and in varying degrees

[1] At the organization meeting, September 21, 1890.

preserves much inherited ferocity, cunning, treachery, and many good animal traits. A higher and still higher expediency development has finally created a type of man who possesses what a modern school of psychology calls the "secondary ego." History abounds with instances. Patriots, missionaries, philosophers, statesmen, leaders and teachers in innumerable fields who have subordinated their own individual welfare to that of country, religion, enlightenment, and no profession has yielded more of this class than has the medical.

The world has not heard of a tithe of those who have willingly given their labor and literally their lives to their ideals of what would benefit others. Multitudes imbued with this spirit have, in the past, been tortured with all the ingenuity of fanatical hate and ignorance. Thousands of unknown Brunos have been burned alive, more unheard-of Roger Bacons have been silenced in dungeons, and sturdy zealots of all religions, with the kindest intentions for those among whom they worked, fill as many untimely graves as do those slain in wars.

But the combat has not ended. Undoubtedly the world has grown better, mainly because principles for which their originators were martyred, have survived. The ignorant, heedless, almost brainless rabble, bask in a sunlight of civilization made possible by the *fiat lux* of thinkers of past ages. Freedom of thought has almost ceased to be criminal, but its advocate with the secondary ego still pays his penalty. As a rule, he is at least misunderstood, and must not hope to have more than posthumous appreciation.

Let us regard a few instances wherein science is antagonized to-day:

Cushing lived among the Zuñi Indians for the purpose of studying the customs and language of this remnant of a prehistoric American race. Land-grabbing speculators found Cushing opposed to their unjust appropriation of some Zuñi lands, and invoked the aid of powerful politicians to crush him. Fortunately for science, a philanthropic organization, with a glimmering conception of what he was about, came to his aid and saved his Smithsonian employment, and enabled him to continue his work, but not before he had been grossly libeled, and his motives basely misconstrued.

Richard Proctor, the astronomer, was cut off from English governmental assistance through the intriguery of an Astronomer Royal, who was more politician than scientist.

A member of this Academy—Frank S. Billings—whose pathological work is a credit to America, found no support, understanding, or countenance of his bacteriological researches in human disease, such as scarlet fever, etc., owing to universal ignorance; and turned to the study of cattle and swine plagues as affording an easier appreciation of scientific results among agriculturalists; and his earliest successes attracted the attention of official "scientists" (pure politicians) in Washington, and forthwith every possible impediment is put in his way by this guild.

It is not saying too much to state that these political "scientists" would rather see America depopulated by some such scourge as cholera, rather than that it should be prevented by some unofficial means.

Prof. Cope, of the Pennsylvania University, has shown that the official geological surveys are debauched by pseudo scientists, who publish great volumes of falsehoods at the government's expense; and recent exposures have damned official American paleontology for all time in necessitating the rewriting of textbooks that assumed the alleged discoveries as true.

I am personally aware that the United States Land Department is officered by politicians as surveyors-general, whose main function is the securing of spoils, and whose mathematical education is the most rudimentary.

Consequently, our public lands are surveyed by subordinates who are willing to pay the politicians' price, and there is left no incentive to good work, and competent civil engineers seek other fields.

We have recently had some ventilation of the methods of securing census statistics and the attempt to accumulate certain information of a private nature through physicians, such as, at one time in the world's history, was piled up at Rome. Any political party may be depended upon to make oppressive uses of such data.

A politically-supervised inquiry into health statistics would be comical if it were not for the menace to the private liberties of citizens. It could be, and would be, made the club for infinite varieties of blackmailing.

That the spoils system in politics has degraded every branch of governmental service there is ample proof, but in one particular its infamies are peculiarly horrible:

Some State charitable institutions are well managed, owing to the personal excellence of superintendents; but this is purely accidental, and in spite of the system. Where a hospital, almshouse, or insane asylum is controlled by aldermen or county commissioners, invariably there is barbarous management, for the spoils party system insures the selection of such officials from the truly criminal classes, and these select subordinates from their companions of a still lower stripe.

Physicians and surgeons in public institutions are regarded by these hoodlums as a sort of necessary evil, and they naturally try to minimize the hostilities between decent medicine and politics by securing as degraded a set of medical men as possible.

Occasionally some skilled student, anxious for the opportunities these public hospitals afford, debases himself by association with officials who can secure places. The result is damaging to the doctor, because good work is simply next to impossible under such auspices. Our Cook County Hospital and Asylum are well enough known to you as undesirable vantage ground for conscientious work.

Occasionally some one, with a view of improving the matter, will undertake to bring the malodorous affairs of our charitable institutions to the attention of a medical society, whereupon the political doctors rush to the rescue, pack the meetings, whitewash, blackmail, break up investigations, and otherwise pollute the society proceedings, to enable a continuance of medical politics, brutal treatment of the insane and sick, and the appointment to positions of ballot-box stuffers and ward "heelers," all to please their masters, the criminals who keep them in office.

This is not a fancy picture, gentlemen, drawn from imagination; it is not only founded on fact, but it is fact.

Shall certain well-known persons who have been guilty of such things gain admittance to the Academy? Can we regard them as suitable accessions from any standpoint? Shall our society suffer the fate of others, and be debased to similar ends?

Medicine and politics make a monstrous, a foul, combination; and are as incompatible as fire and water. The one gains everything by devotion to truth, seeks to elevate everything; the other is the offspring of the father of lies himself, and damns all it touches.

Are we medical men, seeking the alleviation of the ailments of our kind, or harpies, hypocrites, to prey thereon?

It is doubtless true that every medical man is driven to adopt business methods more or less repugnant to his professional instincts, and such practices we need not criticize; but, in view of the incessant thrusting forward of such methods in other medical societies, with the result of debasing their proceedings to catch-penny mountebank shows, it behooves us to jealously guard our portals against encroachments of this business spirit, that elbows away the possibility of concentrating our attention upon the real purposes of our organization.

A great deal is said, and with much truth, about the ignorance and dishonesty of the laity forcing the physician into charlatanism. If money-making is the sole object of the practitioner, then there would be apparent propriety in meeting ignorance and dishonesty upon its own grounds, with its own methods; but let us hope that those who seek entrance to this Academy are prompted by other than mere business reasons. It may be a hopeless task to instruct the masses out of their fetichistic ideas of medicine, and centuries hence new forms of quackery may arise, plundering alike the sick and the learned physician, who has the missionary spirit, the desire to be able to help, coupled with the ability to do so. But, had our Galens, Hunters, Graves, Abernethys, Rokitanskys, Trousseaus, *et id*, of the past, living in far gloomier periods, faltered in their endeavors over such considerations, where would we be to-day?

Though, as Spencer says, what we may accomplish for reform will always be out of proportion to our efforts—the little we accomplish will endure.

Education of the people has been accomplished step by step, so that the world is really better to day than it was; and this education, whatever its shortcomings may be, has been brought about through the singleness of purpose, sincerity and industry of self-sacrificing thinkers.

We, as physicians, as well as human beings, owe them a great debt of gratitude, and they would ask no better recompense than that we carried on the work which they began.

We desire to gather into our organization earnest men who can, and will, by their acts make for our body an enviable reputation, so that it will be justly regarded a great honor to be a fellow of the Academy. While, as Dr. Eccles said in a recent paper in the *Popular Science Monthly*, "medicine attracts to its study the brightest minds and the best intentioned," we must admit that in our ranks there is not only evil coupled with dullness, but here and there are brilliant men who are capable of every duplicity; some there are who cannot help attempting to make tools of everybody and thing; but such persons' habits of thought are hostile to science, and they are not wanted among us. He who practises lies thinks lies, and is incapable of logical reasoning, except as regards his immediate lowest interests.

Diplomacy may answer among politicians, but its effects are damnable so far as correct reasoning is concerned, and such low traits as those of the average politician react upon the possessor, making him a revert, a natural wolf, fox, serpent, or worse.

Pardon my dwelling upon such topics; but my justifications therefor are through experience. The political spirit blights every effort of the well intended to make anything better. Its cursed influence intrudes into churches, societies, mercantile life—everywhere; and it will undoubtedly make many efforts to effect an entrance here.

We have in our midst those who pass current with the laity as honorable, skilful physicians, some of whom, to "get on in the world," have attempted to destroy the reputation of their confreres in the most wanton and unjustifiable manner by systematic scheming. There are others of this ilk, who, leagued with the vilest politicians of our corrupt local government, do their bidding, even to frustrating any attempt of medical or other associations to rescue the insane and sick from robbery and brutal treatment in our public hospitals.

In framing our constitution, I would advise the utmost simplicity and the fewest possible sections. Everything cannot be foreseen and provided for; and as the most astute cannot invent a scheme for good that knaves cannot beat, the decent life of our Academy will depend upon its personnel, and the interpretation it will give to the very plain words "Pure and Applied Medical Science," and that all other matters are foreign. We should regard personalities, intriguery, hair-splitting ethical considerations, politics, and cliqueism as high treason, and full powers should be given to an executive committee, selected for its integrity, to act promptly upon all attempts to prostitute the aims of the Academy, with the right of appeal from such committee to the entire body of fellows.

The originators of this Academy have set their hearts upon its having a glorious, useful and creditable future, and to secure it we must be on the alert against perverting influences.

However much it may "pay" others to subordinate medicine wholly to money-making, let medical topics be the sole consideration here. While those who "serve at the altar must live by the altar," the priest would not think of eating up the entire burnt sacrifice; so the physician, while dependent upon his fees for a living, should not make fee-getting his only aim, even though the most popular practitioners are those who do the people the most harm; for while wrong will always usurp the appearance of right, there is some justification for the belief that the latter triumphs in the end.

In the words ascribed to Wm. Lloyd Garrison (though I am not sure that he is their originator):

"Right forever on the scaffold,
Wrong forever on the throne,
But that scaffold sways the future,
And beyond the dim unknown
Standeth God, within the shadow,
Keeping watch above His own."

SHOULD PASTEUR'S METHOD OF INOCULATION AGAINST THE RISK OF HYDROPHOBIA BE PRACTISED AT A LATE PERIOD AFTER AN INJURY BY A MAD DOG?[1]

By DR. PAUL GIBIER,
Director of the Pasteur Institute of New York.

THE value of inoculations according to the Pasteur method, as a preventive of hydrophobia, being no longer a matter of serious contest, one question remains to be solved: How long after the bite of a mad dog can the inoculations be beneficial?

Evidently, the sooner a person is submitted to the preventive treatment after having been bitten, the

[1] Read before the International Medical Congress of Berlin, 1890.

better it is; but suppose a man was bitten several months, or even a year, ago, are we in a position to assert that it would be of service to subject him to the inoculations?

Relying upon a small number of observations that I lately made, and at the same time bearing in mind that hydrophobia may be developed a year or more after the introduction of the virus through the bite, I believe that the advantages of preventive inoculations to persons who are in this predicament cannot be denied.

Following are a few observations taken from the records of the New York Pasteur Institute, which would seem to show that even at the first apparition of the prodromata of the disease, it is still possible, several months after the bite, to stop the invasion of the germs along the course of those nervous fibers which start from the place of the wound to the nerve centers, and, so to speak, harden the latter against the hydrophobic microbes.

The first case in which a long delay had elapsed between the bite and the moment at which the patient came to be treated was that of a physician, of Carlinville, Ill.,—Dr. C. J. C. F. He had been bitten five months previously, and felt some peculiar sensations at the seat of the scar. These occurred in the right leg, and from this point up along the limb. These sensations became better marked, and proved to be painful enough to awaken the patient in the middle of the night.

The same dog—which presented the ordinary signs of hydrophobia—bit, one day after, Dr. F.'s daughter upon her right side, and inflicted a very severe wound. At the same time that her father felt the signs just described, the young girl felt a disagreeable itching on the spot of the cicatrix of her wound, and was brought by her father to the Institute for treatment. Thus, five months and a half after the bite, both were regularly treated for fifteen days, and received an intensive form of treatment, which ended on the 1st of May last.

One month after, June 2, Dr. F. wrote me: "My daughter and I are getting along nicely; the pains and other peculiar sensations I complained of in my leg are gone. My daughter complains no more, so I think the cure is complete." And two months after the end of the treatment Dr. F. wrote me again that all was going on favorably.

In these two instances, and especially in Dr. F.'s case, if reliance is placed upon what we know of the prodromata of hydrophobia, the symptoms observed would seem to indicate a foreshadowing of others, more serious, and thought to be so by the patient in the light of his professional experience. I think that it is not unreasonable to believe that without the anti-hydrophobic injections the case might have proved unfavorable.

The results in these cases encouraged me to pursue the Pasteur method in other instances, and, so far, I have not had any reason to regret my course.

In a third case, a man from Walleston, Mass., came, April 18, to seek my advice. He had been bitten four months before in the hand, by his own dog; fifteen minutes after, his wounds were washed with a strong solution of carbolic acid.

The day following, the dog bit a companion, who died with the symptoms of hydrophobia. On the 12th of March the dog was killed. I treated the patient from April 18 to May 2. To-day he is well.

A fourth and fifth case refer to two patients who were bitten—the one one month, and the other nearly two months, before. Both are doing well, after a lapse of more than forty days.

A sixth case refers to a boy bitten, fifteen days previously, in the hand. Since the treatment, which ended on the 28th of June, the boy has remained perfectly free from all symptoms of hydrophobic poisoning.

The seventh case is that of a man who came from the province of Ontario, Canada, and who had been bitten thirty-five days before any treatment was commenced. This man was decidedly prostrated when he came; his wounds were severe in both hands; they had not been cauterized. Three animals—two pigs and a cow—bitten by the same dog, died with hydrophobia a few days before the patient presented himself for treatment. Since the end of June he has remained well.

The eighth case is almost similar to the latter, and occurred at the same time. A boy, twelve years of age, came three weeks after having been bitten. A dog bitten by the same animal died with symptoms of hydrophobia just before the patient left his home to come to the Institute. So far he is doing well.

The ninth case is interesting, although the delay was but eleven days between the bite and the first inoculation. A young girl felt a tingling which she described as "sparks" in the tips of her fingers and in the forearm—the seat of the bite. There was free hemorrhage from the wound, and it had not been cauterized. The dog displayed marked symptoms of hydrophobia before dying.

The subject of the tenth observation was a man from Brunswick, Maine, inoculated for the first time seven weeks after a severe bite, inflicted by a dog who had bitten two other men; one of them died thirty-two days afterward with the ordinary symptoms of rabies. The treatment ended on the 12th of July.

Two other patients are still under observation: one, an old man, bitten ten months previously by his own dog, who died a few days after with symptoms of hydrophobia. The little finger, upon which the bite had been inflicted, was neither washed nor cauterized. From the seat of the wound extending to the elbow, the patient felt acute pains, which became worse a few days before he submitted to treatment. Under the influence of the preventive injections, the pains disappeared almost entirely on or about the tenth day.

Finally, another patient, who presents also some interest, is a young lady, twenty-four years of age, bitten thirty-two days before she came to the Institute. For one week she felt worried, without cause, and experienced some pains, extending from the bitten finger to the elbow. She complained, also, of peculiar and rather painful burning sensations in her throat and in her tongue. After six days' treatment she felt better; on the tenth day she was still better, and the painful sensation of the arm appeared only now and then, but greatly lessened in intensity. At the end of the treatment the pains disappeared. The patient had been inoculated three times daily during three consecutive days, and on the fourth day was subjected to a most virulent injection. I believe that the progressive disappearance of the pains must dispel any idea that it was due to mere suggestion.

My purpose is not to advance any statement that there is always time to treat successfully a person who is threatened with hydrophobia after a certain period has elapsed; but I believe that the cases that I have heretofore related, especially if they all prove ultimately successful, may sustain my views; that is, if the inoculations can be performed at least one month before the period at which the invasion of the nerve centers, by the germs, should have occurred,

the probabilities are that a fatal end of the hydrophobic infection will be prevented.

NOTE.—After the reading of this communication a discussion took place, not about the value of the treatment, for that is admitted by every physician who has any experience of the matter, but about the details and modifications applied to the method of inoculations.

Prof. Babés, of Bucharest, recorded several observations and experiments which prove beyond all contest the thorough efficacy of the Pasteur method of treatment against hydrophobia. Among these observations he related a very striking one: In the environs of Bucharest a mad wolf bit thirteen persons and thirty animals—oxes, horses, pigs dogs. The thirty animals died of hydrophobia; a man who neglected to go to the Pasteur Institute of Bucharest to be treated died with the same symptoms; another one died from the wounds inflicted by the wolf; but the eleven persons who received the Pasteur inoculations are still alive, after nearly two years. Those who pretend not to be convinced by such examples, which have been multiplied a great many times, would probably be quite anxious to receive the treatment if they were themselves in danger of contracting the dreadful disease.

MATERIALISTIC STUDY OF CRIME.[1]

BY G. FRANK LYDSTON, M.D.,
CHICAGO, ILL.

SOME years ago, I published in the *Chicago Medical Journal and Examiner* a contribution, entitled: The Pathological Causes of Vice. This was based upon observations of the criminal class during my services as surgeon at the Blackwell's Island Penitentiary, New York, and in other metropolitan institutions. This article, while well received by the majority of my friends in the profession, invoked the wrath of a few orthodox individuals to such an extent that I was stimulated to further discussion and study of the subject. Fanatical opposition is sometimes an excellent evidence that our work is based upon sound principles. And when some of my friends stopped abusing the devil and jumped on to me, I knew I was right.

DISTINCTION WITHOUT A DIFFERENCE, PERHAPS.

In announcing myself as a materialist, as far as the study of vice is concerned, I trust that my position may not be misinterpreted, for it is certainly not my intention to detract from the importance of the moral law in its relation to the production and repression of vice, or to lessen the efforts of the moralist in his attempts to oppose "goodness" to "badness." It is the function of the materialist to liberalize existing theories regarding the causation and repression of vice, and to reduce the subject to a scientific, and, as far as possible, evolutionary basis.

The study of the causes and prevention of vice and crime in their various phases is one of the most important and practical questions of the age. The varying forms of violation of physical, social, statutory, and moral law, which are included under the heads of *vice* and *crime*, are the outcome of certain circumstances of environment and laws of progression which are, and have ever been, present and operable in society; in all social systems, whether of high or low degree of development, and in every grade of civilization. It is obvious therefore, that the philosophical study of vice is a social necessity, quite as much so as is the study of morbid conditions of our physical bodies, resulting from aberrations of physiological laws. Indeed, the two studies are more or less interdependent, and therefore demand the interest of the physician. In my opinion, it is to the physician, and not to the moralist or law-maker, that the society of the future is to look for measures of repression, or the better correction and prevention of vice and crime. Our knowledge of the subject is at the present time decidedly unsatisfactory and crude, from a philosophical stand-point, chiefly because the science of statistics is yet in its infancy, and, to a great extent, because the moralist has acted as an obstructionist and has impeded the progress of those who have undertaken to reduce the question to a purely physio philosophical basis.

I will, at this point, advance the proposition, that the actions of men are governed entirely by the state of society in which they occur. Crimes are the result of precedent circumstances; they are the pictured and tangible results of occult influences, past, present and to come, *i. e.*, they are the result of an all-pervading and everlasting law. Criminal acts are not isolated experiences with no necessary precedent or future repetitions. The doctrine of free will, *i. e.*, of individual responsibility, is so simple and appeals so strongly to the self-esteem and sentiment of the masses that it is accepted by the majority of individuals with a faith and simplicity that prevails on no other question of corresponding magnitude. How simple and satisfactory it is to us to say that our fellow-man has committed a crime, because, forsooth, he is less holy than we! This pharisaical sophistry is but the outcome of human egotism, and as long as it prevails and controls our social, moral and legal efforts at repression, so long will our criminal classes flourish and multiply. Indeed, "he who does not advance goes backward," and our social system is apt to grow worse instead of better.

It is hardly necessary to go into details regarding the superficiality of the prevalent methods of study and repression of crime. It is so apparent that it must strike the most casual observer. Much has been done in the way of moral and physical persuasion, but very little, indeed, in the direction of philosophical methods of the study and correction of causes. As civilization has advanced and theology has become enlightened in its theory and methods, a corresponding improvement in the moral tone of the social body should naturally be expected. Unfortunately, however, there has been no improvement—as far as statistics serve to testify—sufficient to encourage the efforts of the moralist. The futility of moral measures, as demonstrated by past experience, is explicable only upon the ground that there is something more than free will to account for criminal acts. Free will is operable only in the case of individuals, and moral persuasion affects only the individual and, incidentally, the circumstances which sway the volition of the criminal; it accomplishes little or nothing in the correction of the general law underlying the production of the criminal class. By analogical reasoning, the futility of moral means of repression may be readily shown. We will suppose, for example, that a certain portion of the human body is affected by disease, dependent, to a greater or less extent, upon a depraved constitutional condition. Obviously, measures of local correction, *i. e.*, correction of the local depravity of tissue, although useful to a certain extent, fail of their object, unless the general and constitutional influences which tend to enhance the local trouble are recognized and corrected. The individual is but an

[1] Read before the Milwaukee Clinical Club, July 8, 1890, by invitation.

atom of the social fabric; when he is depraved, logic requires a search for, and, if found, the correction of, the morbid general or constitutional influences pervading the social body, which bring about perversion of thought or action in the individual. Moral persuasion is but a minor consideration; the law cannot cope with the question, and punishment is futile, because these corrective influences operate upon the isolated integer and not upon the law of causation. Admitting that certain criminals are so by reason of structural peculiarities, the inefficacy of preaching is at once explicable.

That criminality is the result of certain causal influences, operating by a fixed law, has been recognized by several eminent historical and statistical authorities. Buckle and Quetelet have advanced some striking arguments bearing upon the influences modifying the moral conduct of the human race. It would appear that many of the actions of mankind which we are prone to attribute to free will and independent action upon the part of the individual, are really the result of a fixed and immutable law controlling the moral world, which is almost as definite and arbitrary as the laws controlling the physical world. As compared with this law, the independence, *i. e.*, free will of the individual and the local circumstances of environment, in operation at the time of the apparently volitionary action, are of but little moment, and are but accidents in the chain of events. It has been shown, by the statistics of Great Britain and France, that there is a constant proportion maintained in the ratio of criminal acts to the number of population in those countries.

Rawson[1] says: "No greater proof can be given of the possibility of arriving at certain constants with regard to crime than the fact that, the greatest variation in the proportion of any class of criminals at the same period of life during a period of three years, has not exceeded a half of one per cent."

Quetelet[2] says: "In everything which concerns crime the same numbers recur with a constancy which cannot be mistaken. This is the case even with those crimes which seem quite independent of human foresight—such, for instance, as murders, which are generally committed after quarrels, arising from circumstances apparently casual. Nevertheless we know from experience that every year there takes place not only the same proportionate number of murders, but that even the very instruments with which they are committed are employed in the same proportion."[3]

Buckle[4] says: "Suicide is merely a production of the general condition of society, and the individual's volition only carries into effect what is the necessary consequences of preceding circumstances. In a given state of society a certain number of persons must put an end to their own lives. This is the general law, and the special question as to who shall commit the crime depends of course upon special laws which, however, in their total action, must obey the larger social law to which they are all subordinate. The power of the larger law is so irresistible that neither the love of life, nor the fear of another world can avail anything toward even checking its operations."

Buckle further shows by statistics, that notwithstanding the varying causes of suicide which exist in society, such as political excitement, want, mercantile crises, disappointments in love, depression induced by disease, etc., there has been in London a very constant average of suicides, the average having been during five years 240 per year. The variation in the number was not very great in proportion to the number of population, running from 213 to 266, the latter number being attained in the year 1846, which was distinguished by the great railway panic. At this time the ratio of suicides might naturally be expected to be extremely high, but as a matter of fact, it was less than one-half per cent. higher than the preceding year. Mechanical laws may be disturbed by accidental circumstances, yet they prevail; so it is with the moral law.

As showing how the regularity in the course of events may manifest itself in the most trifling details of every-day life, one of Buckle's statements is very interesting. It is not infrequent for individuals through carlessness to drop undirected letters in the mail box. Such an oversight might naturally be attributed to individual carelessness, but it is shown by statistics that in London and Paris, due allowance being made for varying circumstances, increased population, etc., that there is practically the same number of undirected letters found in the mails every year.

It is generally supposed that in the matter of matrimony the individual is governed entirely by free will. Statistics prove that there is a constant variation in the proportion of marriages corresponding to the rise or fall of the price of food products. So it may be seen that, as far as statistical evidence goes, we may well believe that "there is a Divinity that shapes our ends, rough hew them as we may."

Leaving out of the question a general law influencing society and determining with unwavering fidelity the occurrence of certain acts which we term criminal and vicious, it is unquestionably true that there are certain special causes in operation. The influence of heredity is so well recognized that any remarks in that connection may be considered trite. Yet it would be impossible to do the subject justice without an allusion to it. It is not always an easy matter to isolate hereditary influences from others of a special character which operate in the development of vice and criminality; but there are certain typical cases upon record which conclusively prove that hereditary impulses to breaches of social ethics are a very important consideration in the study of the causes and prevention of vice. There is frequently an intimate association between hereditary defects of a physical character and those manifestations of heredity which result in crime. In many instances a special act of criminality can be directly traced to certain hereditary, or, perhaps, congenital physical aberrations.

The powerful influence of heredity in the production of vice and crime is not so manifest in this country as in some of the older countries of the world. Its influence is not so dominant in countries in which a Republican form of government exists as in those in which an effete monarchial and aristocratic system of control prevails. The older and larger the city the more pronounced its viciousness. Thus it is to London we must look for the very refinements of vice

[1] "Inquiry into the Statistics of Crime in England and Wales."

[2] "Sur l'Homme," Paris, 1835.

[3] "During twenty' years study of the statistics of crimes in France, the number of accused persons registered scarcely varies at any age from year to year, comparing the proportionate percentage at each age with the totals. The number of persons accused in all France from 1826 to 1844 was about equal to the deaths of males registered in Paris; but, singularly enough, the results of the former are more regular than the latter, notwithstanding the accidental causes which might affect them; notwithstanding even a revolution in Paris which convulsed society and brought on a new dynasty." (Brown on the Uniform Action of the Human Will.)

[4] "History of Civilization in Endland."

and crime. The exposé of the hideous orgies of Cavendish Square followed very closely upon those sensational murders of women which attracted the attention of the whole world to the great Metropolis.

In Dr. Ireland's book, "A Blot on the Brain," we have evidence collated which is sufficient to convince any thinking man that the aristocracy of the Old World is hereditarily rotten to the core. You are familiar with his unmerciful handling of the House of the Romanoff's, which is so eminently true that the sale of the book has been prohibited throughout the Russian domain. I do not claim that the aristocracy *per se* are more liable to viciousness than any other class of people similarily situated. Unbridled license, idleness, and the possession of unlimited resources, when taken in connection with the circumstance of consanguinity or inbreeding, are enough to account for the corruption of the dominant element in European society. That actual physical aberrations or atypical conformations of structure must bear a certain responsibility, for the development of the criminal class is amply shown by the researches of Benedict and Osler. These experimenters have shown quite a constant relation between atypical cerebral development and criminality. The assertion that criminals and a certain class of insane exhibit a defective or aberrant brain development, has been the conclusion of such students of the subject as Corre, Lombroso, Mills, Rouselmarro, Pavlosky, Varaglin, Tenchini, and Badik. To be sure we must take into consideration the näive declaration of Benedict that "certain of these cases were collected as the result of *a priori* conviction that the criminal is an individual having the same relation to crime as his next blood kin, the epileptic, and his cousin, the idiot, have to their common encephalo-pathic condition.

Hackneyed as the illustration may be, there is as yet no better exemplification of the effects of heredity than that embraced in the wonderful tables and statistics of the immortal Richard Dugdale in his history of the "Jukes." In these tables the histories of 1,200 descendants of one Ada Juke—more popularly known as "Margaret, the Mother of Criminals"—are traced, and of the total number nearly 1,000 were shown to have been either criminals, drunkards, or paupers.

Ribot, in his famous work on Heredity, has shown remarkable examples of an inherited predilection, not only for crime in general, but for certain forms of crime and vicious impulse. But I perceive that my paper is spinning out to an unwarrantable length, and I will, therefore, present as briefly as possible those causes which students of this important social problem should be always ready to recognize.

1. The first and most potent cause is that occult, all-pervading and remorseless law which pervades all social systems. To this law I would apply the term *predestination* were it not, in my opinion, too arbitrary an expression, and likely to lay me liable to the impeachment of illiberality. This cause has already been sufficiently expatiated upon. There appears to be an occult influence of an epidemic character affecting chiefly the crimes of murder and suicide. This is so trite that I would scarcely mention it, but for my desire for completeness of classification. There has recently occurred in rapid succession in numerous large cities in this country a considerable number of cases of wife murder, followed by suicide. These cases are an illustration of a peculiar kind of homicidal mania of an apparently epidemic character, which occurs now and then. It is my opinion—and in this I am not alone—that the public press fosters this epidemic influence by its blood-curdling accounts of such cases. It is a question in my mind whether the complaisant manner in which the *minutiæ* of robberies and defalcations are recited by the newspapers, has not its influence in producing crime.

2. Hereditary impulses, independent of perceptible or obscure physical aberrations. It is possible that habit, persisted in through succeeding generations, may result in a faulty power of reasoning, which, although not characterized by variations in physical conformation, may be transmitted to posterity through countless generations.

3. Defective physique and imperfectly developed intellect, hereditary or congenital. These cases are of the plainest type and are admitted by all.

4. Acquired disease, lessening the moral sense and will power. Instances of this kind are familiar to all of us. Vicious or criminal acts, performed under the influence of acute delirium, or mania, due to various diseases, are frequently met with.

5. Injuries to the brain. This cause of crime and vice is a very familiar one, especially to the alienist and neurologist.

6. Alcoholism. To this cause there are many who—in what I consider illiberality—attribute nearly, if not quite, all cases of criminality. There is no question but that alcoholism is a potent cause of crime, but there are thousands of cases of criminal acts which are apparently traceable to it, in which the influence of alcohol is secondary to physical causes, inherent in the individual. There were certain interesting facts brought out by the recent Congress of Alcoholism, in Paris, which illustrate the importance of the study of the relation of alcoholism to crime. It was shown, for example, that there was quite a constant relation between the amount of alcohol consumed in various social systems and the amount of crime. It is my impression, however, from a study of the statistics developed by this congress, that the survey of the field of criminality had been rather a narrow one, and that certain collateral elements in the causation of crime had failed to receive their due meed of consideration. Some of the studies of the congress were rather interesting in this connection. For example, it was shown that in Berne, where there are only four saloons per thousand of inhabitants, criminality was more prevalent than in Zurich, where the proportion is twelve to the thousand.

7. Vicious example and surroundings. Environment. This involves the question of "criminal contagion," which is very important in connection with our own defective methods of correction. The herding together of all grades of criminals is one of the most pernicious systems that could be devised. In my own city of Chicago, for example, there is no reformatory for young lads, and they are therefore sent to the Bridewell, where they inevitably become contaminated by older criminals. This proceeding is as rational as would be the sending of a case of simple sore throat to a diphtheria hospital.

8. Defective education and consequent imperfect mental discipline. This is a question in which the progressive physician and the philanthropic politician, if such a *rara avis* exists, should be a unit.

9. (a) Perverted conception of law, statutory, moral and divine; (b) unjust dispensation and maladministration of law. This cause is of more importance than is usually assigned to it. What may be termed the inequalities of justice have been responsible for fully as many cases of confirmed criminality as almost any other cause which could be mentioned.

Bishop Robertson once said: "Justice is a pair of huge iron jaws which open and close with mechanical regularity. Nearly every man at some time in his life comes within the legitimate reach of these jaws. Many escape just at the nick of time because they do not happen to be within reach when the jaws are opening and closing, while others, less guilty perhaps, but also less fortunate, are caught."

A very interesting story is told in this connection, of two school boys who were stealing apples together. They were detected and pursued. One was caught, while the other escaped. The one who was captured was sent to jail and thrown among criminals from whom he acquired a moral contagion which infected his after life. After his release, those acts which before his incarceration had been merely boyish pranks, assumed a criminal character, and he became a confirmed criminal. The boy who escaped remained in school and doubtless kept up his mischievous pranks during the rest of his school-days. He afterward studied law, became a lawyer, and eventually was elected a judge. Twenty-five years after the apple-stealing episode, the judge sentenced his former comrade to death for murder.

10. Alleged detective science or man-hunting. The manner in which the ambitious modern would-be detective pursues discharged criminals is an apt illustration of "man's inhumanity to man." How frequently it transpires that a criminal leaves the prison gates with the resolve to lead an honest life; he secures a position, but the eye of the law is still upon him, and some human tiger in the guise of a detective speedily warns his employer that he is harboring a jail bird. Discharge follows, and perhaps another place is secured with the same result, and so the relentless pursuit goes on and on until the jail bird finds every avenue closed to him except the road back into the jail. Why have we not a Hugo among us to describe the persecution of our many Valjeans by aspiring and relentless Javerts? It is unquestionably true that the persecution of ex-convicts by our would-be Vidocqs does much to keep up the census of our jails. A want of faith in reformation, on the part of those who should hold out a helping hand to the criminal, drives many a man back to crime.

11. Physical, moral, social, and matrimonial mésalliances. This involves the question of consanguinity. It is questionable whether we as physicians will ever succeed in accomplishing much in the correction of this particular cause. A sanitary marriage is the dream of the idealist, but if we shoot at the moon, we may make a pretty satisfactory target, though we fall far short of the mark. Gross physical infirmities and certain pronounced mental defects, at least can be taken into consideration in the question of matrimony. Proper selection in marriage means both physical and mental improvement in the race. The human animal is certainly entitled to some of the benefits to be derived from the science of breeding. Authorities are somewhat divided upon the question of consanguinity, yet there are few who are not willing to admit the necessity of careful and ripe judgment in considering the question of the marriage of blood relations.

12. The intermarriage of criminals. As much has been said upon this question, it is doubtful whether the correction of this influence by the State is possible. If the privilege of matrimony be denied to the criminal class, illegitimate relations are apt to be established with an even more deplorable result. Such people are not apt to stand on ceremony, and the correction of this cause is therefore more theoretical than practical.

13. Corruption in politics. Under this head I will embrace political encouragement of ruffianism and protection for criminals. A very sad case recently occurred in Chicago, of a prominent lawyer who became insane as a consequence of a blow upon the head, inflicted by an alleged respectable citizen during a quarrel of a political character. As a corollary of political corruption, we have an imperfect and corrupt police system, the keystone of which is the aphorism that it takes a rascal to catch a rascal. This cause of criminality must prevail as long as the credentials of an alderman are the qualities of a deep, hard drinker and a good rough-and-tumble fighter.

14. Niggardly and misapplied charity, with consequent failure to relieve actual want. As is well known, starvation and crime are first cousins. Here is the golden opportunity for the philanthopist!

15. The importation of the criminal refuse of the Old World, and, what is worse, individuals with fanatical, social, political or religious views. The important question of immigration demands more attention than is usually accorded it. It is really one of the most vital issues of the day. The instance has been known, and quite recently, that nearly ten thousand immigrants were landed at Castle Garden alone, to say nothing of other ports of entry. Were it established that all of these people are respectable and producing elements in American society—as a large proportion undoubtedly are—they would certainly be a very valuable addition to our population.[1] There is something striking, however, in the fact that, although the foreign-born citizens constitute but one-eighth of the total population of the country, they furnish one-third of our criminals, one-third of our paupers, and one-third of our insane. In short, the character of our immigrants is so polluted by the wholesale exportation by the Old World, of the insane, criminal, and pauper class, that every one thousand immigrants furnish twenty per cent. more of the inmates for our jails, asylums and alms-houses than the same number of American born. This is a cause which must be grappled with by the statesman and not by the philanthropist. Should politics become honest, or approximately so, there is hope for removing this evil, but under the present system of political quackery a remedy for this cause is like some of the others I have mentioned, more theoretical than practical.

In this array of generalities and necessarily imperfect classification of the causes of vice and criminality, it is obviously impossible for me to entirely cover the field, but if I have succeeded in presenting in an intelligible manner ideas which will serve as an incentive for the study of the subject on the part of my hearers, I shall have accomplished my object. As Dumas once said of mendicity, "criminality is an organized body, a kind of association of those who have not, against those who have." It is high time that the respectable elements of society should begin the study of the causes and prevention of crime, in a philosophical manner. If this be done, and the philosopher, preacher, statesman, jurist and physician, put their shoulders to the wheel and work in unison, the time may come when the criminal class may not be so pronounced a curse in our social system, as it is to-day.

[1] It will of course be understood that there is no prejudice involved in my remarks, which are directed at the importation of tares with the wheat.

CHLOROFORM IN OBSTETRICS.

By W. R. D. BLACKWOOD, M.D.,
PHILADELPHIA.

ANYTHING which tends to the comfort or safety of mankind (and this applies with redoubled force to the woman in labor), is to be welcomed; it is a good thing. Dr. Baldwin has given to the profession, in his interesting paper of September 27 in THE TIMES AND REGISTER, some cogent reasons why, in his opinion, chloroform is demanded in all cases of confinement; this we may safely assume, because he makes it the second item in his triad. He refers to the usual objections which have been urged against the use of this anæsthetic in labor, and gives the experience of himself and others to show that there is no real reason why chloroform is unsafe or to be avoided. He adduces the fact (or what he believes to be a fact), that the circular fibres of the cervix and the muscles of the perineum are highly relaxed by the agent in question, and this he takes as a good thing: yes, I know, that is so! But chloroform exercises no selective action on particular muscles; *all* the muscles of the body are relaxed equally, according to the depth of anæsthesia—the muscles of the uterine body just as much as those of the cervix. This I hold from my own observation. In so far as this goes, so far there is loss of expulsive force. He says that he never had a case of post-partum hemorrhage, neither did Dr. Fordyce Barker (under chloroform). In my own practice during the years when I worked hard at obstetrics for myself and my preceptor, I had charge altogether of a little more than thirty-two hundred labors, and, although in none of them did I encounter the dreadful complications which appal the neophyte when he reads about them in the text-books and in periodical literature, I had, toward the end of the row, several cases of flooding. In each instance of this bad business *anæsthesia had been practised!* Dr. Baldwin says that injury to the child has never been reported as the result of using anæsthetics, but I have more than once seen reports the object of which was to check the misuse of chloroform for the very reason in question, viz., its possible bad effects on the infant when prolonged administration was desirable for any reason; in short, the last of my confinements shows this thing to be a fact. The child was born after the woman (a doctor's wife) had been semi-unconscious all day from anæsthesia under chloroform, owing to terrible convulsions; the child was unusually active prior to the use of the drug, but it took hard work to revive it after its birth, and those present will bear me out in the statement that the difficulty was owing to the cause named.

For some years, my confreres in this end of town were bothered by the antics of a crank who educated the community through treatises stuck under their doors, depicting the wonderful journeys which thousands of women took with him to picnics of varied nature (the aforesaid tramps happening through the agency of a combined chloroform mixture of his "own make") to the belief that it was criminal to have any other doctor than himself, unless his patent free-pass inhalation was employed to secure a trip of the nature depicted, and since the people got "onto him" and his dodges, it has been found by his successors that hemorrhage was a quite common occurrence in his practice. That chloroform has inherent dangers, I don't believe. I gave it in many hundred cases during the war, and now and then since that time, and in no instance have I ever seen the slightest symptom which would lead me to refuse its aid in my own case were I to undergo an operation requiring anæsthesia; but I know that deaths have occurred, in some instances anyhow, and chloroform was blamed for them, so, as the paper which I now refer to is calculated to invite indiscriminate use of this powerful agent in labor, I think the brakes should be either put on a little, or held in readiness, for that this habitual use of chloroform in the way suggested would be a boon to women, without any possible drawback, I seriously doubt.

246 North Twentieth street.

The Polyclinic.

MEDICO-CHIRURGICAL COLLEGE.

FOR DIARRHŒA:

℞.—Tinct. opii camph.,
Tinct. lavandulæ comp.....āā ℥j.
Sp. vini gall..... ℥ij.
M.—S. ℥ss every three hours.

—*Stubbs.*

FOR THE PAROXYSMS OF ASTHMA:

℞.—Potassii iodid..... ʒijss.
Tinct. lobeliæ ..... ʒiv, ♏x.
Syr. sarsaparillæ comp. ...q. s., ad ℥ij.
M.—S. ʒj every two hours till relieved.

—*Anders.*

SORBEFACIENT IN PLEURISY:

℞.—Syr. ferri iodid..... ʒijss.
Potassii iodid. ..... ʒj, ℈j.
Syr. sarsaparillæ comp..... ℥j.
Aquæ..... q. s., ad ℥ij.
M.—S. ʒj four times daily, in water.

—*Anders.*

FOR CARDIAC DROPSY:

℞.—Digitalis..... gr. xij.
Sennæ fol... ..... ʒss.
Aquæ bullientis..... ℥vj.
Fiat infusum, et adde:
Sodii iodid..... ʒij.
Sodii phosphat..... ʒvj.
M.—S. ℥ss every three to six hours.

—*Gerhard.*

ALTERATIVE FOR TERTIARY SYPHILIS:

℞.—Potassii iodid..... ʒijss.
Syr. acidi hydriodic..... ℥j.
Aquæ destillat..... ℥iij.
M.—S. ʒij thrice daily, in a wineglassful of rice water (to detect free iodine).

—*Gerhard.*

FOR ENLARGED PROSTATE WITH CYSTITIS:

℞.—Ergotinæ,
Pil. hydrargyri pulv. ....āā ℈j.
Salolis ..... ℥iij.
M. et divide in partes æquales No. xx et in capsulas gelatinas dantur.
S. Take one capsule thrice a day.

PSYCHIC SEQUELÆ OF TYPHOID FEVER.

IN a paper presented to the Pennsylvania State Medical Society in 1886, the writer gave the history of two cases that served to illustrate the point of his argument: that severe and prolonged attacks of typhoid fever sometimes leave behind them alterations of the mental state, as well as physical lesions. As these cases have been buried from the light of day in the transactions, in which alone they were published, we will reproduce here the history of one case.

The subject was a boy of good habits, loyal and affectionate in his disposition, not very bright as a student, but somewhat dull in business matters, giving no evidence of any special ability of any sort. For all that, he was steady, and devoted to his parents. In 1876 he had typhoid fever; a long and severe attack; lying in bed for thirteen weeks, under an expectant treatment. During the whole period of his delirium he raved about money. Visions of wealth, and the urgent need of money for his business, were the subjects of his waking and sleeping dreams. When, at last, he recovered, he remarked one day that he must go down to the bank and draw some money. Inquiry showed that he believed himself the possessor of balances amounting to hundreds of thousands, the fact being that he had not a penny on deposit. His friends endeavored to convince him of this, but to no purpose; though he was silenced, he never acknowledged his mistake. When he began to go about, he acted fully up to the part of a young man of unbounded fortune; went to the wildest extravagance, dissipation of every sort, raised money in every possible manner, honest and otherwise, and was finally compelled to leave the city. Since that his career has been checkered. He developed a remarkable talent as a canvasser, of which he showed no trace before his illness. This has been the means of securing him good situations wherever he went; but sooner or later he has always become involved pecuniarily, and had to give up. From city to city he has gone, repeating this history in each. Sexual excess, syphilis, and alcohol, have each added their effects to that produced by the original trouble, the fever. But from his convalescence he showed evidences of a total change of disposition. The change was shown in his total loss of all sense of moral obligation; of his previously warm affection for his family, of which he now rarely displayed any evidence, save what he assumed for motives of extortion; his delusion of wealth; and the development of unusual capacities in one line of business.

Throughout the years that have since passed, there has been a slow but gradual development of his malady, that is now assuming the form of paranoia. To the operation of the degenerative causes already mentioned, may be added that of absinthe; which he has been drinking for some months.

His present condition may be judged from his latest exploits: He began purchasing goods in a lavish manner; ordering clothes, jewelry, etc., when his pockets were empty and his family hungry. He bought a watch, signing the name of a firm to the order; arranged for the purchase of a little child's pony and cart—an utterly useless thing to him. He excused his extravagance by claiming that he had made a sale that would net him over $1,000; but so far was this from the truth, that the firm to whom he claimed to have sold the goods had not bought them and had no intention of doing so, as they were not such as they used in their business. Many similar eccentricities occurred; as the result of which he found himself in prison. Here he remained for several weeks, long enough for the effects of alcohol to disappear, and he was released. He immediately telegraphed to his family that he had made $1,000 within an hour after his release, and $12,000 within a week; the truth being that he had done nothing at all.

The difficulty with this case has been that, while his friends have considered him of unsound mind, he had done nothing so palpably insane as to justify them in putting him under restraint. Even now, although his countenance is assuming the characteristic facies of dementia paralytica, it is uncertain whether he could be legally restrained. The only possible course has been to wait until the progress of his disease shall have brought him to that condition in which his mental alienation is manifest.

To the eye of the public this man is simply a rascal; but nobody who has followed the case from childhood can fail to see that the turpitude dates from the typhoid attack, which ended at a stroke his innocent life; and from that period he has been another being.

This is not an isolated case. In the article in which this was described, another instance was related of mental aberration following typhoid, but of another character. Syphilis is said to frequently occasion a loss of the sense of moral obligation; as many an unpaid doctor will testify. If the subsequent history of patients recovering from severe attacks of septic fevers was carefully studied, we would find in the profound alterations of the tissues the source of many cases of depravity. Such a study would, we believe, shed a light upon the pathogenesis of crime; and enable us to look upon the unfortunates of the criminal class with that "mercy whose quality is not strained," and yet not outrage the

sense of justice, which metes out punishment where deserved.

In men whom men declare divine
I see so much of sin and blot—
In men whom others class as ill,
I see so much of goodness still—
I hesitate to draw the line
Where God has not.

Annotations.

AND now our distinguished visitor, Professor Miller, is said to have alleged that caries of the teeth may be transmitted by kissing.

If Professor Miller has nothing better in the way of advice, he had better have stayed at home. What! And so many pretty girls about as there are this season, too! We don't believe a word of it!

PIRACY on the high seas is supposed to be a thing of the past; but when we read of a Malay cook and crew conspiring to poison the whites on a vessel and take her to their islands, we wonder whether we live in the present, or if the days of Marryat and Tom Cringle are returning. This is the story brought to Philadelphia by the ship "Lizzie Troop."

THERE is one manufacturer who has the manliness to publish his little journal for just what it is—an advertisement of his wares. Every number of Stearns' *New Idea* comes to us with a postage stamp affixed. Compared with several other manufacturers' periodicals, the *New Idea* is not a whit more of an exclusively advertising medium for the publishers than the others, which enjoy second-class privileges. These are the things that make legitimate journalism difficult. One of these imitation journals parades its "Entered as Second-class Matter" before our faces, when, since its first appearance, there has not been a line in its pages that has not been a direct advertisement of the goods its publisher had for sale.

A NEW dodge is reported in Western mortgages. Taxes are prior liens. In Kansas, if not paid, the property is sold, redeemable within three years, with twenty-four per cent. interest added annually. A company is alleged to allow lands securing its loans to be sold for taxes, buys the certificates, and notifies the mortgagers that, to protect their interests, they must take up these certificates and twenty-four per cent interest, and that the money realized from such sources is used to pay interest upon the debenture bonds. In one case the holder of a guaranteed mortgage found that this land was sold for taxes nearly three years ago, so that he must buy up the certificate at once, with seventy-two per cent. added, together with all subsequent taxes and twenty-four per cent. interest thereon, or lose his security altogether.

DR. STEMEN, in the *Journal of the American Association of Railway Surgeons*, speaks as follows of the editorial comments on his book on Railway Surgery:

In looking through the journals we find some very favorable notices of the work on railway surgery, and a few not so favorable; but, of the latter, it is only necessary to say that the *reviewers* are not among the leading editors in this country; in fact, we find that they were unable even to write a notice of the work without violating the rules of English composition; but we are glad to know that but three of the medical journals have had anything unfavorable to say of the work.

Does Dr. Stemen believe his work above the reach of criticism? One who puts a book before the public must expect blame as well as praise, and not plead the baby act. We found the book deserving of some commendation and some blame; creditable as a pioneer work, but with many crudities.

We give the author credit for capacity to give us a much better book in the next edition—one which will do justice to an important subject. If, however, strictures which are well meant and perfectly just, are met with a spirit of wounded vanity only, railway surgery must look elsewhere for its spokesman.

HOSPITAL FACILITIES.

OUR attention has been called to the great disproportion in the number of beds reported as at the command of the medical colleges in Philadelphia; and to the fact that this is due simply to a different method of making the report. Thus, the University reports 1,100 beds; but this includes those in the various hospitals with which members of the faculty are connected. This was so specified in the report furnished us, and should have appeared in our Student's Number. The Jefferson College reports only the beds in the College Hospital; as does the Medico-Chirurgical. The University Hospital has 150 beds; the Jefferson the same number; the Medico-Chirurgical will contain about 110 when the present alterations are completed. The Philadelphia, Pennsylvania, Orthopedic, German, Philadelphia Lying-in, Wills and Episcopal hospitals are open to all the colleges alike, and the members of the faculties of all the schools are connected with the staffs of nearly all. The Children's Hospital is, we believe, controlled exclusively by the University, though students from other colleges are admitted to the clinics. From this it will be seen that none of the Philadelphia colleges can justly claim any superiority as to clinical facilities.

Letters to the Editor.

CHILLS DURING PREGNANCY.

MRS. L., aged twenty-four, has three children, and has had one miscarriage. Married when sixteen. First child delivered with forceps, on account of spasms. During the following pregnancies she suffered considerably with chills, and was told by her attending physician that she must have no more children. She is now three months pregnant; has been running down in health for two months, and for three weeks has been having two violent chills a day, morning and afternoon. No appetite, but does not vomit; has insomnia and headache, pain in back. Before chills, passes large quantity of light-colored urine. An examination could find no albumen or sugar.

I at first thought there was malarial poisoning, but quinine was given without effect. There is no elevation of temperature. I have given, besides quinine, digitalis, Basham's mixture, sp. ætheris comp., and am now stuck, as she is steadily losing strength. There has been no sexual intercourse since chills began.

H. A. S.

[We would suggest a careful examination of the liver and spleen; also, put a drop of blood under your microscope and look for pigment. In spite of the failure of quinine, we look upon malaria as the most likely cause of the chills, and would give quinine in full doses if there is any elevation of temperature during or after the chills. If not, the chills can be only evidences of nervous perturbation, and the remedies are to be directed rather to the mind than the body. Throw aside altogether the advice of former attendants to bring on an abortion—advice too readily given in that it generally meets the patient's wishes half-way. Make an independent investigation of the patient's genital apparatus, and see if there is any real reason for apprehending danger. If not, the confident assurance of safety will prove a valuable therapeutic measure. If no material cause can be found for the symptoms, rest assured that they are due to fear or unwillingness to bear the pangs of maternity. Valerian or viburnum should be of value here, and an effort should be made to forestall the chills with chloroform, morphine, or pilocarpine. Lorini's elixir of coca sometimes proves of efficacy in restoring the nervous system to a normal condition.

--W. F. W.]

Book Notices.

Wood's Medical and Surgical Monographs. Volume VII, No. 3. September, 1890. Price, $10.00 per annum; $1 00 per volume.

Contents: Insomnia and its therapeutics. By A. W. Macfarlane, M.D. Index for vol. vii.

A Treatise on Hfadache and Neuralgia, including Spinal Irritation and a Disquisition on Normal and Morbid Sleep. By J. Leonard Coveing, M.A., M.D. With an appendix: Eye-strain, cause of Headache. By David Webster, M.D. Illustrated. Second Edition. New York, E. B. Treat, 5 Cooper Union. Price, $2.75.

This is one of the best works the publishers have as yet issued in this series. The author's apparatus for local treatment shows much ingenuity. We recommend the book to the consideration of our readers.

The Physician's Companion. A Pocket Reference Book for Physicians and Students. By C. A. Bryce, M.D. Pp. 164. Cloth, $1.00. Leather (especially for the pocket) $1.25. Richmond, Va., The Southern Clinic, 1890.

Contains a summary of practice, symptomatology and treatment, surgery and emergencies, diseases of women, obstetric emergencies, infant feeding, poisons and antidotes, medical odds and ends, etc.; in a word, about all those things one can want in a little book that can be easily carried in the pocket without spoiling the set of the coat. It is evidently not the work of a closet physician, but of a real practitioner who knows something of the real needs of his class. As such we recommend it to our readers.

Recherches Cliniques et Thérapeutiques sur l'Epilepsie, l'Hysterie et l'Idiotie. Par Bourneville, Sollier et A. Pilliet. Vol. X, avec 22 figures dans le texte et une planche chromo-lithographique. Paris, aux bureaux de Progrès Médical, 1890.

These records of the year's experience of the learned physician to Bicêtre and his colleagues are of great value; not only to the specialist, but to the physician at large. It is, indeed, to be regretted that the group of affections treated here is relegated to the specialist; for better results could hardly fail to be secured if each physician could treat a few cases intelligently. For of all classes of hospital patients, none are so certain to be neglected as these; while the results of *individual* treatment are brilliant.

The amount of work recorded in the present volume may be inferred from the fact that over 44,000 baths were given.

The bromide of gold was employed in ten cases of epilepsy. Of these, in three there was a "notable amelioration;" in five, a "light diminution" in the number of convulsions; in the others, no benefit ensued. The general effect on the bodily health was good. The drug was given in single daily doses, of varying size, and for long periods. This confirms our own opinion as to the reputed efficacy of gold, published some months ago in this journal.

The bromide of camphor, however, again proves of marked value in cases of epileptic vertigo.

Of ten cases treated by picrotoxine (half a milligramme daily, increased to two milligrammes), two showed undoubted improvement, three slightly improved, the rest became worse.

Familiar Forms of Nervous Disease. By M. Allen Starr, M.D., Ph.D. Professor of Diseases of the Mind and Nervous System, College Physicians and Surgeons, N. Y. Wm. Wood & Co., N. Y.

This work does not claim to be a "treatise" on nervous diseases, but it succeeds better than most so called treatises, in so far as it goes. It helps the general practitioner to such guides, so that he can recognize the nervous diseases most commonly presenting themselves, and have at the same time a clear conception of the lesions present, and of the available therapeutic resources. And this is done inside of 321 pages of very readably printed type. The illustrations are generally very well adapted to their purpose, except that in some of them the reference figures are troublesome to manage on account of being printed on dark backgrounds. It is not likely that the general practitioner could get what he wants as quickly from most other works on neurology, on such subjects as Jacksonian epilepsy, aphasia, locomotor ataxia, infantile paralysis, and many other frequently occurring forms of disease. S. W.

Pamphlets.

Transactions of the N. Y. State Medical Association, for the year 1889. Volume VI. Edited for the Association by Edward K. Dunham, M.D. Contains twenty-eight papers besides minutes of the proceedings.

Local Boards of Health in the State of New York. Albany: The Argus Company, Printers. 1890.

The Treatment of the Morphine-Disease. By J. B. Mattison, M.D., Home for Habitués, Brooklyn, N. Y. Reprinted from the *Therapeutic Gazette*. Detroit, Mich.: George S. Davis, Publisher. 1890.

Dr. Mattison is an expert in the treatment of morphinism, and whatever he says on that subject will be found both instructive and interesting.

Longevity and Climate. Relations of Climatic Conditions to Longevity, History, and Religion.—Relations of Climate to National and Personal Habits.—The Climate of California and its Effects in Relation to Longevity. By P. C. Remondino, M.D., San Diego. Read before the Medical Society of the State of California.

Comparison Between Perineal and Suprapubic Cystotomy, With Report of Cases. By A. Vanderveer, M.D. *Albany Medical Annals.*

The Medical Digest.

FRENCH NOTES.

By A. E. Roussel, M.D.

Strychnine as an Antispasmodic.—At the Berlin Congress M. Benedikt, of Vienna, remarked that strychnine was generally considered as stimulating the medullary excitability. In a girl of twelve years affected with a mimic spasm, which showed itself by twitching of the lips and complicated by an ordinary chorea, M. Benedikt tried without result all the different forms of treatment used in similar cases. The idea then occurred to him to make use of the treatment first pointed out by Trousseau, which consists in the use of strychnine. He, therefore, prescribed :

℞.—Subnitrate of strychnine..... 0 gr. .10.
For twenty pills. Take from three to five pills in the twenty-four hours.

The effect of the medication was striking. Both the spasm and the choreic movements diminished, and in a very short time the young patient was cured.
—*La Médecine Modern.*

The Use of Sulphonal in Diabetes Mellitus. According to Casarelli sulphonal has an efficacious action in the treatment of saccharine diabetes. The author summarizes as follows :

1. Sulphonal exercises a favorable influence in diabetes. Thanks to this remedy we notice a diminution of sugar and of the quantity of urine, a diminution concomitant with the polydipsia.

2. This amelioration manifests itself but to a slight degree it is true, even after the use of 1 to 2 grammes a day, but it becomes marked after doses of 3 grammes in the twenty-four hours repeated several days in succession.

3. Even when continued for a long time, sulphonal in doses of 2 grammes does not provoke any unpleasant secondary phenomena. Given in doses of 3 grammes a day, it is at first well tolerated ; but if continued it is soon followed by extreme somnolence and vertigo. But a reduction of the dose will soon do away with these troubles.

4. The good effects of sulphonal is equally well manifested with an absolute meat diet. If we stop the sulphonal in this case we will at once find abundant sugar in the urine.

Casarelli gives to this substance marked preference to antipyrine, which in his hands has given markedly inferior results in the same condition.
—*La Bulletin Médicale.*

The Use of Valerian.—Valerian possesses a real efficacy in that group of maladies of women designated, for want of better, under the names of *nervous state*, *spasmodic* condition, etc. It has an incontestable therapeutic action against certain *hysterical phenomena*. It acts well in those cases of *vertigo*, *etourdissements* similar to those which announce the danger of a cerebral hemorrhage, and which, however, is not allied to this grave affection. It is equally employed in *choreic anæmia*. It renders service in a number of cases of *simple paralysis*, and in a general way it diminished the production of urea.

Formulas Relative to the Preparations Most Used.—
1. Extract and Root.—Bolus of Valerian :

℞.—Powdered valerian..... 0 gr. .25.
Powdered cinnamon..... 0 gr. .05.
Honey.....q. s.
For one bolus ; take from four to twenty a day.

Confection of Extract of Valerian :

℞.—Extract of valerian..... 20 grammes.
Powdered valerian..... 20 "
Powdered orange leaves.....q. s.
Five to forty grammes a day, and even more if necessary.

Antispasmodic Lavement :

℞.—Valerian root..... 30 grammes.
Make infusion with boiling water.. 250 "
Filter and add :
Asafœtida..... 4 gr.
Yolk of egg..... No. 1.

Antihysterical Pills :

℞.—Powdered valerian..... 8 grammes.
Galbanum,
Sagapenum,
Asafœtida.....āā 4 grammes.
Make pills of 0 gr. .20 ; three to four a day.

Antineuralgic Pills (Roger) :

℞.—Extract of valerian,
Asafœtida,
Galbanum,
Castoreum.....āā 0 gr. .05.
For one pill ; three to four a day.

Antispasmodic Potion :

℞.—Valerian..... 8 grammes.
Make infusion in boiling water.... 150 gr.
Filter and add :
Distilled canella water..... 60 grammes.
Sulphuric ether..... 8 "
Simple syrup..... 40 "
A tablespoonful each hour.

2. Valerianate of Ammonium.—Pills :

℞.—Valerianate of ammonium..... 1 gramme.
Extract of valerian..... 1 "
Powdered valerian .....q. s.
For 40 pills. Take from 20 to 25 a day.

Potion :

℞.—Valerianate of ammonium..... 1 gramme.
Syrup of mint..... 30 "
Tilia water..... 120 "
Two to five tablespoonfuls each day.

Lavement :

℞.—Valerian root..... 20 grammes.
Boiling water..... 300 "
Valerianate of ammonium..... 0 gr. .50.

3. Valerianate of Atropine :

℞.—Valerianate of atropine..... ½ to 1 milligr.
Simple syrup..... 25 grammes.
Tilia water..... 120 "
One tablespoonful each hour.

4. Valerianate of Iron.—Tonic Pills :

℞.—Valerianate of iron..... 1 gramme.
Extract of cinchona.....q. s.
For 20 pills ; 2 to 10 a day.

Pills for Chorea :

℞.—Valerianate of iron..... 4 grammes.
Extract of cinchona.....q. s.
For 40 pills ; 3 a day.

5. Valerianate of Cinchona.—This salt is administered with excellent results to combat neuralgia; it gives equally good results in typhoid fever with delirium.

Lavement :

℞.—Valerianate of quinine..... 0 gr. .50 to 1 gr.
Hot water..... 150 grammes.

Pills :

℞.—Valerianate of quinine..... 2 gr.
Extract of cinchona.....q. s.
For 20 pills.

Potion :

℞.—Valerianate of quinine..... 0 gr. 50 to 1 gr.
Sweetened infusion of cascara.... 125 grammes.
Tablespoonful at a dose.

Capsules :

℞.—Valerinate of quinine....From 0 gr. .25 to 0 gr. .50.
To each capsule.

In typhoid fever we give 1 gr. a day divided into two doses.

6. Valerianate of Zinc.—Antispasmodic Pills :

℞.—Valerianate of zinc..... 4 grammes.
Extract of cinchona..... 2 "
Subnitrate of bismuth..... 2 "
For 40 pills; 3 to 4 a day.

Powder :

℞.—Valerianate of zinc..... 0 gr. .05.
Vanilla sugar..... 1 gr.
For one dose; 1 to 4 a day.

—*La Bulletin Médical.*

For Dyspepsia (Dujardin Beaumetz):

℞.—Maltine..... 1 gramme.
Powdered bicarbonate of soda.... 1 "
Calcined magnesia ..... 2 "
Powdered white sugar..... 10 "
Mix with care and divide into 20 parts; one part after each meal

—*Journal de Méd.*

Treatment of Cancer of the Stomach (Peter). —The treatment of cancer of the stomach presents two indications to fulfill; 1. To combat the hyperemia of the pepsin cells which surround the neoplasm. 2. To stimulate the appetite.

We treat the first indication with success by counter-irritants on the pit of the stomach, a blister kept open for some time.

To stimulate the appetite, we have recourse to the bitters, of which the best is the liquor of Baumé.

We will give from one to three drops before each meal. To facilitate digestion, we will administer a small quantity of hydrochloric acid: 10 drops in 200 grammes of water, and 50 grammes of syrup of lemon. One or two tablespoonfuls at a dose.

—*La Bulletin Médical.*

A Tennessee doctor is credited with delivering two children with a pair of shoemaker's pincers, using the carved handles as obstetric forceps.

An Alabama doctor tells about a patient of his with neuralgia, who took a sharp cornered rock and broke a hole through his cranium, and poured swamp water in to cool off his brain.

We are ready now to hear from the man who performed an iridectomy with a monkey wrench, and a Cæsarean section with a buck saw. There's nothing like expedients when you are in a pinch.

—*The Country Doctor.*

Newspaper Reading.—The average reader, busy with his own engrossing cares, skims lightly over the thousand facts massed in several columns. His eye learns to neglect almost everything, and only here and there delays long enough on some subject of personal interest, or of exceptionally striking, or terrifying effects. The influence of all this on the reader's mind is very disastrous. To win his attention he must be amused, excited, terrified. Quiet, thoughtful consideration of any subject seems to him tame. Marshaling of facts, pro and con, and deduction therefrom, have no part in his mental processes. His mind hurries from one subject to another, and his resulting ideas are crude, while his thoughts are loosely and carelessly arranged. Clearness of perception and exactness of expression are wanting, so that from his desultory reading comes only superficial thinking. The mind staggers under the load of mere facts and ceases to grow and strengthen.

—Russell, quoted in *N. Y. Med. Times.*

Case of Chyluria.—About ten days ago I was consulted with regard to a girl, five years of age, who had passed milky urine for several days. Upon microscopical examination of the urine, it was found to contain innumerable specimens of *filaria sanguinis hominis.* I did not examine the blood, but shall if the case continues. I placed her upon gallic acid, and four days later failed to find filariæ, though the urine was still somewhat chylous.

As the patient was born in this city and was never out of the county, it is undoubtedly of local origin. I believe such cases are more frequent than we know of; but the true diagnostic means—the microscope—is not made use of as frequently as it should be.

Tyson states that he only knows of one case of chyluria of North American origin. Five cases were collected by Dickinson, which, however, all originated in England.

Jaksch does not mention a case of North American origin, though he quotes from Wucherer, Lewis, and others, in tropical countries.

—Weiss, *N. A. Practitioner.*

New Uterine Curette.—Being urgently in need of a large sized curette for a special case, I devised one as follows: Having a universal handle belonging to a cotton-holder, I took the wire of the holder, which is seven and one quarter inches long, and inserted a loop of watch-spring between the split end, putting in two rivets, and soldering up the openings to make it impervious to blood and septic matter. The spring is three-quarters of an inch in diameter, and one and one-half inches in length inside of the loop. It is one eighth of an inch wide, and the usual thickness of watch-springs. This answered my purpose satisfactorily. If a smaller one is required, a slide could be put over the wire carrying a compressor that will make any size opening down to three eighths of an inch. Any watch-maker being able to put in the spring in twenty minutes, a set of three or four can be made at nominal cost, thus furnishing the physician with a simple, cheap, and effective instrument for removing foreign material from the uterine cavity. The spring being so thin, it will seldom be necessary to sharpen the edge for removing vegetation, etc. Brass wire is used to hold the spring.

—Alford, *Weekly Med. Review.*

Medico-Legal.— Russell (*Journal of the Nat. Assoc. Railway Surgeons*) describes a case in which he was sued for damages in a case he never treated, and cast for two thousand dollars' damages. A new trial was refused. He appealed to the Circuit Court; refused an offer from the prosecution to settle at one thousand dollars; the court ordered a new trial, which was contested bitterly, and the jury took just ten minutes to find a verdict in his favor. Reviewing the question of the physician's legal responsibilities, he reaches the following conclusions:

1. A physician or surgeon, without a special contract for the particular case, is never considered as warranting a cure.

2. His contract, as implied by law, is that he possesses a reasonable degree of learning, skill, and ex-

perience, which is ordinarily possessed by his colleagues in the profession, and that he will use reasonable diligence in the treatment of the case, and good judgment in all cases of doubt as to the best course of treatment.

3. He is not responsible for want of success, unless it is proved to result from want of ordinary skill, or from want of ordinary care and attention.

4. He is not presumed to engage for extraordinary skill, or for extraordinary diligence and care, without the same is specified in the contract.

HAY FEVER.—In the *State Board of Health Bulletin*, (Tenn.), Dr. Daniel F. Wright, of Clarksville, a member of the Board, advocates the idea of the curability of this pestiferous malady. He thinks that by anticipating the annual recurrence of the disease and resorting to a locality free from its etiological factors for several consecutive seasons, the unfortunate individual will secure an immunity from his trouble that will be permanent. He speaks in high terms of Roan Mountain (Cloudland), in upper East Tennessee, and from his article we submit the following extract:

"Let it not be supposed, however, that I am about to set forth the specific virtues of some new drug for this purpose, or even those of certain mineral waters impregnated with miraculous chemical ingredients. The only merits possessed by the waters here consist in their perfect purity; and the atmosphere is beneficial simply from its coolness, moisture, and its freedom from dust of all sorts, including that vegetable dust which is constituted of the pollen of various plants. Very few of the plants which constitute the Roan Mountain *flora* give any pollen to the atmosphere, by far the greater number consisting of *coniferа*, *ferns*, and *labiates*, while the great moisture of the air prevents the rising and diffusion of such as might otherwise irritate the nostrils of visitors. In short, the qualities of air and water are simply negative—they simply fail to supply the irritants which are elsewhere the exciting causes of hay fever."

—*Southern Practitioner.*

OBSTRUCTION OF ILIAC VEIN.—The next patient was a man twenty nine years of age. About nine years ago he was suddenly seized with a sharp pain in the posterior aspect of the knee-joint and radiating up the thigh. Immediately afterwards he noticed a swelling of the leg below the point the pain was first experienced, and a progressive enlargement of the veins of that region. His trouble gradually increased in severity until it terminated in the formation of ulcers around the ankle joint and other parts of the leg. By maintaining his leg in an elevated position and by the use of an elastic stocking used conjointly, it was found possible to relieve all the symptoms; but last year the ulcers became more obstinate than usual, and have refused to heal under any treatment whatever.

On his entering the Polyclinic Hospital a diagnosis of obstruction of the iliac vein was made by Dr. Wyeth. As it was a matter of the greatest importance to the patient to prove that such was in reality the case, an exploratory incision under ether was performed. An incision was made through the abdominal muscles above Poupart's ligament and the iliac vessels exposed to view. The iliac vein was found to be obliterated. The abdominal wound was closed under strict antiseptic precautions, prompt union taking place.

The patient was advised to try what could be accomplished by the use of well fitting elastic bandages and an elastic stocking to support the circulation in the limb, and if that should fail in bringing about the desired result, amputation above the knee joint should then be resorted to.—*Internat. Jour. Surgery.*

CONTAGIOSITY OF TUBERCULOSIS.—Last fall I was called to see Mrs. Lone Bull, an Indian, who had had a hemorrhage from the lungs; examination revealed well marked pulmonary tuberculosis. About Christmas I visited Lone Bull's family and found them living in a cabin with but a single room, which admitted of little, if any ventilation. There was living, and had been for some time, the family of Grey Haired Bear in the same room, also a young man Lucke Low Buck and his sister. I advised the urgent necessity of their finding different quarters, but my counsel was not heeded. In January, Mrs. L. B., was confined, giving birth to a child that soon developed and succumbed to tubercular meningitis. I feel convinced that the child received the infection through the mammary glands of the mother, who was by that time in the last stages of consumption. Mrs. Grey Haired Bear had hemorrhages, and began to waste away. Lone Bull's daughter, eight years of age, developed tuberculosis, and is having hemorrhages. Low Buck's sister, six years old, died with the same disease. Grey Haired Bear's son of four, broke down and died of consumption. His second son, aged two, had whooping-cough, which was followed by tabes mesenterica, and resulted in death. Mrs. G. H. B. died in April, Mrs. L. B. in May; Low Buck is still alive, but very ill. Lone Bull and Grey Haired Bear both have pulmonary tuberculosis. The cat belonging to these unfortunate people was constantly on the floor, and lapped the sputa expectorated by them; soon it sickened, wheezed, coughed, became emaciated, and died. Could the contagion of small-pox or scarlet fever be more certain in their results?

—Treon, *Cincinnati Lancet-Clinic.*

CHRONIC SYNOVITIS.—I shall now present to you a patient illustrating in his lower extremity one of those sequences so frequently met with after fixation and complete immobilization of a joint, especially in the case of people whose circulation is very defective. This man's knee joint had been injured by a fall, and he had necessarily to be subjected to treatment by fixation and rest.

Most of you will recollect the lecture I delivered in this hall on the treatment of Colles' fracture and the great stress I laid on not confining the fingers in a bandage. I then stated to you that the fingers should be left free, so that the tendons could play in their sheaths and the little joints remain flexible. If the joint of any aged person be confined for a certain length of time—even though it be not injured—the joint thus confined will become stiff. The folds of the capsular ligament will have assumed such a strained position that as soon as the patient makes an attempt to move his joint, the very act will elicit pain.

The condition in the joint of this man is somewhat analogous to what I have just described. We have here a chronic synovitis of the ankle-joint due to compression and fixation of the parts. He is now adopting the very best kind of treatment that it is possible to give him, viz.: walking and taking active exercise of the joint. This will be supplemented by stimulation of the local circulation by means of hot water douches upon the limb, and when the vessels appear to be all distended with blood, when the circulation has become active, then by the employment

of massage, commencing at the toes up to the knee-joint and the use of passive motion of the joint. This will be done once a day, and in a short time he will recover the full use of the limb.

—Gerster, *Internat. Jour. Surgery.*

Electricity in Pelvic Disease.—1. Myomata should receive a thorough trial by electrolysis before attempt at extirpation.

2. Interpolar electrolysis is sufficiently well established to expect good results in reducing myomata without puncture, if a strong current be passed directly through the tumor. Puncture should wait upon interpolar electrolysis.

3. All inflammations of the uterine adnexa should be treated by electricity thoroughly, before laparotomy is resorted to, for many cases are amenable to this treatment.

4. There are some cases of pus-tubes that may be best treated by opening the uterine end of the tube and securing drainage through the uterus. Others should be punctured by electricity, through the vagina.

5. Ectopic pregnancy should be treated by electricity as soon as a diagnosis is made, either by galvanism, to kill the fœtus, or by faradism, to expel the same, provided it has not passed the fourth month of gestation, or there is not actual or impending rupture of the tube.

6. Electrolysis is the proper treatment for cervical stenosis.

7. Galvano cautery is a superior means of extirpating uterine cancer, in many cases.

8. Early diagnosis and proper treatment of endometritis by intra-uterine electrolysis will cure most cases, and prevent many cases of salpingo-ovaritis.

9 All surgical procedures that may be performed by electricity are better so performed because of the incidental influence upon nutrition.

10. Electricity is a conservative measure of great value in the treatment of nearly all pelvic diseases where the knife is now used.

—Sprague, *Weekly Med. Review.*

Sanitary Teaching.—The greatest obstacle to the correct application of sanitary principles is either the ignorance or carelessness of those likely to be benefited. Men of general intelligence will allow their farm-yards, their cellars, their ponds and drains to be breeders of disease, which may endanger not only their own lives, but that of the neighborhood, simply through carelessness, or fear of temporary expense. It is true the health boards have been of inestimable benefit to the community where they are located; but if every physician would constitute himself a health officer in the neighborhood where he resides, pointing out the breeding-places of disease, not alone in pond and ditch and swamp, but in the houses and the out-door premises of his patients, he would have a much more satisfactory, if not as lucrative, practice. If the masses of the people possessed that education in sanitary matters which every physician should be prepared to give, the death-rate, in the rural districts especially, would be very much lessened. A striking illustration of the danger to an entire community by the ignorance and obstinacy of a few individuals is seen in the rapid spread of the cholera in Spain; so great is the opposition of the peasants to any change in those conditions upon which the very existence of the cholera depends, that the government physicians will no longer visit them unless protected by a strong military escort. If the lives of those in the immediate district were only endangered through their own obstinacy, they might be left to their fate; but the seeds of disease ripening among them are scattered broadcast, and spread from nation to nation. Of course, in our own country we seldom meet such ignorance and obstinacy; but every physician will find an abundant use for all his information upon sanitary matters, which information should be volunteered whenever it will be productive of good.

—*N. Y. Med. Times.*

Prolapse of Funis.—Prolapsed funis should be treated as follows: When a case is met, every precaution should be taken to preserve the membranes intact until the os is fully dilated and the head well down upon the perineum, observing in the meanwhile the circulation through the cord, which will at all times indicate the condition of the child, or any impending danger. When labor has progressed sufficiently, or the pulsation of the cord show danger, rupture the sac, apply the forceps and deliver quickly as need be. Should the case be one in which the liquor amnii has been discharged and the os not yet dilated, insert two fingers into the os in such a manner as to receive the cord between them to protect it from pressure; after each pain push back the head, if pressure upon the cord is indicated by impeded circulation. Continue this until the os will permit the use of forceps, when, if symptoms indicate, apply them and deliver. Should the cord protrude from the vulva it should be placed loosely within the vagina, as few kinks in it as possible, where it is to be kept for warmth while a portion is held between the thumb and finger, or against the finger, that the circulation in the cord and the progress of labor may be noted. The cord is to be relieved from pressure on the subsidence of each pain by pushing the head back. When the pressure can no longer be thus relieved satisfactorily, the forceps and delivery are demanded.

This practice, as briefly outlined, has been adopted by the writer in all cases of prolapsed funis since 1872. Previous to that time he, being timid about the use of forceps, tried the various other methods as taught. The result was that, previous to 1872, out of five cases met, five children were born dead—since 1872, and including that year, thirteen cases have been met and thirteen children been born alive, among which was one weighing fifteen pounds.

But I think I hear some say, Is there no danger of lacerating the cervix, or rupturing the perineum? Yes, some. But the child is entitled to a good deal of consideration at the hands of the obstetrician at all times, and the integrity of a cervix or perineum is not to be considered when the life of a child is in jeopardy. They can be repaired, but the life of a child can never be restored.

—Reed, *Toledo Med. and Surg. Reporter.*

Homonymous Hemiopic Hallucinations.—The following history of a case of paranoia presents something unique in the way of visual hallucinations:

H. K., aged twenty, single, came to the Vanderbilt Clinic, June 10, 1890, complaining of persecution by unknown persons. He had noticed since January last that "mesmeric influences" were being used upon him, and the conspirators, three in number, have been redoubling their annoyance as time went on. He has unilateral hallucinations of hearing. There are three voices in his right ear, all talking to him and not to each other. They tease him, swear at him, curse him, and call him names. In addition to

these uni aural polyphonic hallucinations, he is tortured by disagreeable odors and by peculiar tastes in his water and food.

His visual hallucinations are singularly limited to the right visual areas of each eye, so that we may, in fact, speak of them as homonymous hemiopic hallucinations. He sees at times skeletons and various people, but always moving about and upon his right side, and this is true if either eye is shut. They never appear upon his left side. If he directs his eyes toward his right side, where the vision appears, they move still farther toward the right.

He complains of paræsthesiæ, flashes of heat and waves of cold through his body, jerkings of his muscles and viscera, and pains in his trunk and limbs, all of which he ascribes to electrical devices. Most of the pains in his trunk are restricted to the right side, but there is no unilateral distinction with regard to those of the limbs.

His hallucinations are conjoined with the delusions of persecution already mentioned. He thinks there are several persons, certainly three, who control him by mesmerism and annoy him by telephony and electricity. He has purchased a dozen books on mesmerism and clairvoyance, hoping to gain sufficient knowledge of the subject to be able to counteract the schemes of his enemies. Latterly his attention has been called to hypnotism and suggestion, and to the ease with which people may be influenced to commit theft and murder under such control, by reading the newspaper interviews with some of our leading specialists. He had copies of these interviews in his pocket and showed some of the illustrations, among which was that of a man, under hypnotic influence, plunging a dagger into another. The patient intimated that he had some fear of being made to carry out some nefarious undertaking by his imaginary hypnotizers.

Although no heredity could be ascertained, he exhibits marked facial asymmetry, and in particular a remarkable malformation of the hard palate, showing that he belongs to the superior degenerate classes. His is in fact a typical case of paranoia with systematized delusion of persecution which have been evolved from a degenerative soil.

The case is related, however, merely on account of the very remarkable character of the visual hallucinations. Their limitation to the right visual fields of both eyes is absolute proof of their central origin, and they doubtless arise through irritation in the cortical visual area of the left occipital lobe. It would seem as if the cortex of the left hemisphere was the chief seat of disturbance in this case.

Unilateral hallucinations of one eye alone, or uniocular hallucinations, have been described by several authors as occurring in the insane, but, so far as I know, this is the first reference that has been made to visual hallucinations of the character herein mentioned, and for which I can find no simpler name than that which forms the title of this article.

—Peterson, *New York Medical Journal.*

ELIGIBLE VEHICLES FOR QUININE.—Doubtless every pharmacist and physician has his favorite method of disguising the taste of unpalatable drugs, but not every one is aware that the enterprise of manufacturing pharmacists now offers such a variety of vehicles from which to choose.

Some rely almost exclusively on pills and capsules, whereby the drug is smuggled into the stomach without recognition by the gustatory nerves. But there are patients whose apparatus for deglutition is so constructed as to render it almost impossible for them to swallow pills or capsules, as well as cases where it is all-important to secure immediate absorption of the medicine. When given in pill form, no matter how soluble the mass, an appreciable time must elapse before the remedy begins to have its effect.

How then can we administer quinine in solution or suspension—particularly to children or delicate ladies—without causing a disturbance in the family every time a dose has to be given? To children quinine may often be given advantageously by inunction, and the oleate of quinine especially, applied to the surface in this way, is readily absorbed and produces promptly the characteristic effect of the drug. Suppositories must not be forgotten in cases where the stomach is particularly irritable, and the hypodermic injection presents itself as a dernier resort when a prompt and powerful influence is required. But in ordinary cases quinine may be administered by the mouth.

One plan is to mix the quinine with some alkali or astringent, so that the bitter sulphate or muriate becomes converted into the tasteless alkaloid or tannate.

Another plan is to combine with the quinine a mixture having a bitterness of its own, which shall blend with and modify the intolerable bitterness of the quinine, some aromatic being generally added to still further disguise the objectionable taste.

It is on this principle that cascara cordial operates, and many of those who have tried this vehicle, declare that it is the best that has yet been offered. The especial advantage which it possesses over all others is the fact that it is a laxative agent, and so renders more efficient the action of the antiperiodic.

Licorice has been long known as having a remarkable power of covering the taste of bitter medicines. This property is due to a peculiar principle called glycyrrhizin, a glucoside, insoluble in water and in acid solutions, but readily dissolved by the aid of alkalies.

When quinine is given in powders, it may be rendered nearly tasteless by simply rubbing it up with a small quantity (one-fourth its weight) of ammoniated glycerrhizin (ammonium glycyrrhizate).

"Fluid extract licorice, for quinine mixtures," is one of the most efficient of all the preparations employed for covering the bitter taste of quinine. The best way to use it is to drop a dose of the powder into a little of the fluid extract contained in a spoon, mix it thoroughly and swallow at once.

Aromatic elixir of licorice is to be used in the same way as the fluid extract, but is especially useful in the drug store when a single dose of quinine is called for to be taken at once.

Yerba Santa contains a principle analogous to glycyrrhizin, which renders quinine in its presence as tasteless as starch. It appears to act like glycyrrhizin by producing a peculiar impression upon the gustatory nerves; it does not, as stated by some, produce with the quinine an insoluble compound. Unless the mouth is thoroughly rinsed after taking the mixture, a bitter taste will gradually develop as the nerves recover from the influence of the yerba santa.

To some persons the taste of yerba santa itself is disagreeable, and when this is the case licorice is to be preferred. Barring, however, idiosyncrasy in this respect, we can recommend the preparations of yerba santa as the best means of rendering quinine tasteless. Aromatic syrup of yerba santa renders it possible to give little children full doses of quinine without the vigorous remonstrances which physicians and parents have learned to regard as inevitable.

—*Northwestern Pharmacist.*

NERVOUS SEQUELÆ OF TYPHOID FEVER.—Dr. Kearns said: "A twelve-year old boy, in the third week of typhoid fever, ceased to speak even in monosyllables, and this condition continued for about ten days. During this time there was no apparent impairment of intellect. Sitting at the bedside of the patient and telling him to put out his tongue, he did it instantly. Telling him to look toward me that I might examine his eyes, he did it instantly. The pupils of the eyes were markedly dilated. Then, at the expiration of these ten days, the case assumed the very opposite condition and he became loquacious; he would take up any conversation which occurred in the room and follow it up repeatedly. This condition continued day and night, with some short intervals of rest, for ten days, when it gradually stopped. The pulse was accelerated during the period of excitation. It was at a normal rate during the period of quietude. All this time the stomach had been in good condition. Now, here are two extremes. What condition of the brain and nervous system was involved in these conditions of two extremes in the same patient and the same disease? This cerebral excitation was very difficult to control. The remedy which had the desired effect was calomel. I administered one-quarter of a grain of calomel every two hours, and when the bowels began to run off, gave smaller doses. I ascribed the symptoms to a complicating meningitis.

Dr. Thomas said he had been called to a thirteen-year-old boy who had been sick about a week. The fever ran an ordinary course. About the twenty-first day there was defervescence, and the patient seemed to be convalescent. He visited the boy as long as he remained in the city, and in the meantime he would not speak a word until the day before he went away, he got him to say one word. He did not feel uneasy about him, his temperature not being above normal. He went into the hands of Dr. McNeil. On his return he found the boy all right, and was told that in speaking to his grandmother, upon his beginning to talk again, the first word he said was "cracker." He said "cracker, cracker, cracker" for three or four minutes; then he ceased calling for crackers. Dr. Thomas looked upon the symptoms as caused by anæmia of the brain.

Dr. Stewart had observed a case where a man lost power in the right arm. The loss was progressive, and then he had convulsions. The convulsions were in the arm affected. Subsequently they became general and he would become unconscious. The convulsions became very frequent—several times a day. An operation was performed under the supposition of lesion in that area. The man had had syphilis. Potassium iodide had had no effect on the case. The brain was uncovered and only a localized meningitis was found. Incisions were made into the brain, but nothing was found. The man ultimately recovered the perfect use of his arm, and had no more convulsions.

Dr. McKennon said it was not uncommon for peculiar mental states to follow typhoid fever—mental weakness, and very frequently mental exhilaration. He had seen many cases of insanity due to typhoid fever. He had never seen meningitis in a child with typhoid fever. The weight of authority supported the supposition that the lesion was purely of a functional character, and that there was rarely structural lesion. Some authorities admitted the possibility of embolism which involved one artery.

Dr. Lang said that no matter what cerebral symptoms may occur in typhoid fever, there was no justification for the assumption of meningitis. No matter how violent or how peculiar were the cerebral symptoms, the assumption of meningitis was not correct nor justified. Typhoid fever and meningitis are not necessarily incompatible, but autopsies on typhoid fever which presents most violent and most ataxic symptoms have so invariably proven the absence of meningitis, and of all inflammation, that such symptoms cannot be correctly assigned to meningitis or to structural lesion, but to the effects of typhoid fever poison. He could not understand how the speech center could be affected by meningitis without previous greater injury to the motor areas, which, being in closer apposition to the meninges than the center of speech, would primarily, and to a greater extent, be subjected to meningeal pressure. For this reason paralysis was as common in meningitis as aphasia (barring comatose cases) was rare.

—Transactions, Allegheny Co. Med. Society.

Medical News and Miscellany.

DR. YERKES has removed to West Chester.

DR. H. J. LACIAR, of Bethlehem, is quite ill.

DR. DAVID D. STEWART has removed to 1310 Walnut street.

DR. R. CHESTON, of Chestnut Hill, is down with typhoid fever.

DURING 1889 there were 1,356 deaths from delirium tremens in England.

DR. DANIEL KARSNER is about to remove to Green and Tulpehocken streets.

CHOLERA has reappeared at Toledo, Spain; and four cases are reported at Jerez.

DR. A. E. ATKINSON has been nominated for Congress in the 18th District of Pennsylvania.

DR. W. S. LONG, of Haddonfield, was married last week to Miss Florence Roe, of Woodbury.

DR. TULLEDGE has left the milky ways of Conshohocken for the wider fields of Philadelphia.

DR. JOHN D. WARE, of the Cook County Hospital, Chicago, has returned from his summer vacation.

DR. DA COSTA has purchased the "Ashewood" mansion at Villanova, and is greatly improving it.

DR. HENRY LEFFMANN gave a Health Talk at the Y. M. C. A., October 2, illustrated with a stereopticon.

PROF. J. M. MAISCH delivered the opening address at the Philadelphia College of Pharmacy, October 1.

DR. H. C. FULLER has tired of the monotony of Jersey Shore, and erected his tent at Mahanoy City.

IF THE EARTH were an absolutely round ball it would be covered with water to the depth of 10,000 feet.

THE introductory address at Jefferson Medical College was delivered, on October 1, by Prof. W. W. Keen.

THE wife of Dr. Dostaler, of Maskinonge, Quebec, was struck by a train and instantly killed, last Wednesday.

DR. D. P. VER VALEN, of Philadelphia, was married, on October 2, to Miss Anna L. Lewis, of West Chester.

THE Bedford Street Mission has closed its baths for the season, having had 30,672 bathers during the summer.

DR. AND MRS. LOUIS STARR are back from the Adirondacks, and are in their pretty house on Rittenhouse square.

DR. JOHN A. FRITCHEY, Mayor of Harrisburg, has declined the nomination for Congress in the Fourteenth District.

THE State Senatorship of Montgomery county appears to be between Dr. Markley and Dr. Todd. Hobson's choice.

DR. A. VICTORIA SCOTT, of the National Women's Health Association, lectured on Poisons in Drinking Water, last week.

DR. J. WILLIAM WHITE has returned from his European trip and is in his city residence on South Rittenhouse square.

DR. W. P. HOWELL, of Philadelphia, is supplying Dr. Gillow's place, as resident at the Pennsylvania Hospital, temporarily.

DR. G. I. CULLEN has assumed the editorial chair of the Cincinnati *Medical Journal.* We wish him success in his undertaking.

MEDICAL students should notice the numerous attractions for young men at the Y. M. C. A., corner Fifteenth and Chestnut streets.

THE Rev. John A. Dowie, President of the American Divine Healing Association, is running a mission in the First M. E. Church of Chicago.

ONE of the severest tests of an intelligent gentleman is to sit and listen patiently and politely to the advice of a d—d fool.—*Clarksville* (Tex.) *Enterprise.*

A NUMBER of the guests at a Trenton party were taken violently ill; canned lobster getting the blame. Dr. Horace G. Wetherill was among the victims.

WE are not yet done with His Satanic Majesty, La Grippe. Just listen to the squealing of life insurance stockholders, as their dividends are cut into with wide swathes.

PROF. GEO. A. PIERSOL delivered the opening address at the University of Pennsylvania, October 1. The medical class on the opening day numbered over five hundred.

DR. GEO. J. NEWGARDEN, Resident at the Philadelphia Hospital, has resigned in order to accept the position of medical examiner at the Pension Office in Washington.

AN epidemic of dysentery prevails in Sussex county, New Jersey, with many deaths. The disease is said to have originated from a filthy pen where hundreds of hogs are kept.

THE Pennsylvania Board of Charities have sent a letter to the officers of the Lancaster county prison condemning that institution as unfit to be used for jail purposes.

DRS. E. M. GREEN and W. O. SEMPLE, of Easton, are now delighting their Easton friends with the strange and thrilling experience of their tour in the wilds of Europe.

DR. MCGONEGAL, a homœopathist of New York city, has been convicted of manslaughter in the first degree, for causing the death of Annie Goodwin by criminal malpractice.

BETWEEN eighty and ninety is the number of this year's Freshman's class in the college department of the University of Pennsylvania. Last year's class was somewhat larger.

SEVERAL cases of leprosy have, it is reported, been discovered in Englishtown, Cape Breton Island. The victims are said to have been in constant association with the other inhabitants.

THE celebration of the crystal wedding of Dr. and Mrs. T. H. Andrews, that was to take place next month, has been postponed, owing to the death of Mrs. Walter George Smith.

THE Flower, Fruit, and Ice Mission held its Sixteenth Annual Meeting October 1. During the season 13,542 bouquets were distributed to the hospitals, and $684 were expended for ice.

DR. WICKERSHAM, Health Commissioner of Chicago, has ordered that no Inspector of his department shall vaccinate any one on the leg in future without special instructions. He says it's a foolish freak of girls that he will not encourage.

A CORONER'S jury, after wrestling with Dr. Formad's chirography, brought in a verdict of death by being knocked down and shocked. Death was due to shock, is the probable rendering.

THE Societè d'Hygiene publishes a paper by Pietra Santa, strongly advocating the removal of the prohibition of American pork, which he pronounces a cheap and wholesome article of food.

CHICAGO is said to have organized a company with $20,000,000 capital, to construct and operate a line of air-ships. They will carry cars the size of a Pullman, accomodating fifty passengers each.

A PATIENT in the University Hospital, suffering from an aneurism In his left leg, is now undergoing the tedious but very successful treatment of cure by digital pressure, at the hands of Dr. J. William White, the resident staff, and relays of medical students.

AN artificial musk has made its appearance, a white, crystalline body with the characteristic odor. It is, unfortunately, almost as costly as the real Tonquin musk. Mr. F. E. Morgan, of Walnut street, below Seventeenth street, Philadelphia, has a specimen.

THIS is the refrain of a song sung by two hundred and fifty Wellesley College girls, who nearly raised the roof, the other day:

Life is all a grind;
Yes, all a grind
'Tis to my mind;
Though many joys some find,
Yet life is all a grind.

A NEW source of lead poisoning has been discovered in Chicago. It seems that millers are in the habit of branding their flour-sacks with heavy blotches of paint, which soaks through the cloth and into the flour.

DR. ROBERT A. SANDS was married to Miss Kate Van Valkenberg last week. Among the guests were Drs. Fordyce Barker, J. W. McLain, D. M. Stimson, Willard Parker, H. A. Griffin, G. W. Bratenahl, and several other physicians.

MINNEAPOLIS had 249 deaths in August; corresponding to an annual rate of 14.94 per 1,000. Considering that this was in summer, with 35 deaths from cholera infantum, 44 from gastro-enteritis, and 22 from dysentery, the rate is exceedingly low.

CAN'T SUIT EVERYBODY.—"Why are you and Dr. Bronson on the outs?"

"You know my rich uncle George?"

"Yes."

"He was at the point of death and Bronson saved him."

PENNSYLVANIA EYE, EAR, AND THROAT INFIRMARY, at Thirteenth and Chestnut streets, treated, during September: New eye patients, 228; ear patients, 94; throat patients, 19; total, 341. Eye patients made 1,167 visits; ear patients 844, and throat patients 221.

DR. JOSEPH LEIDY, JR., of the Pennsylvania Hospital staff, has returned from a trip through Europe. He says he had more trouble in getting in and out of Russia than he had in any other European country, and had to show his passport to almost every one he came in contact with.

WHAT wonderful progress is made in medicine nowadays? In the *Bulletin Medical* a prescription is given of sulphur and cream of tartar for constipation; while, in the *Indian Medical Gazette*, a contributor gravely indites a formula for calomel and jalap for the same purpose.

THE Bayard Taylor Annex School, at Fifth and Tioga streets, Philadelphia, has been closed to prevent the spread of diphtheria among the pupils; a child living with the janitress in the building having died of that disease. The building has been fumigated, and was reopened this week.

DR. MOFFETT, of Fifth and Venango streets, Philadelphia, deserves great credit for the prompt action he took in counteracting the effects of the laudanum drunk by John Reilly, a young man living at Lawrence and Venango streets, who purchased the same of the doctor at his drug-store.

HARRY W. SHEETZ has just been tried and convicted of putting to a frightful use his power as a mesmerist over a Miss Cookenbach, who made the startling statement that she had been hypnotized by Sheetz three times, and compelled to live with him twice as his wife and once as his daughter.

CHILDREN'S HOSPITAL OF THE MARY J. DREXEL HOME, August 23 to September 27: Patients in hospital August 23, 28; admitted since, 30; discharged cured and improved, 26; died, 2; remaining, 30. Accident cases, 9; free patients, 22. In the dispensary, 582 cases were treated: Eye clinic, 93; prescriptions, 267.

THE University of Michigan, in Ann Arbor, has opened with the largest showing ever made in its history. This is much to the surprise of the officials, as the required course in the medical department is four years, instead of three. Everything points to over a hundred gain for this year.

A CHICAGO jury has just found that a "child came to its death from suffocation, produced by a female cat inhaling her breath while in her cradle." This was in accordance with Dr. Strzyzewski's testimony. As the cat was found lying directly across the baby's face, the child was probably suffocated.

THE Mutual Medical Aid and Beneficial Society of Pennsylvania is about being organized. It has for its object the furnishing to its members medical attendance and pecuniary relief in case of sickness, accident, or death; benefits being obtained from weekly or monthly dues collected from the members.

SURGEON-MAJOR HARRIS, of Simla, India, has devised a process for removing the emetine from ipecacuanha, leaving the powdered root otherwise unaltered. It is thought that the curative virtues of the drug in dysentery are retained, without the attendant nausea, and a clinical trial is being made, with promise of success.

AT the annual meeting of the trustees of the State Hospital for the Insane the following officers were chosen: President, C. H. Stinson; Dr. E. G. Martin, of Allentown, Secretary, and Treasurer Bradley were also re-elected. Dr. Lillian S. Welsh, of Columbia, was elected an assistant female physician, to succeed Dr. Quindora McQuaide, resigned.

Not being a woman we suppose our opinion on woman's books is not of much consequence; but we nevertheless feel compelled to say that the October number of *The Home-Maker* is simply charming, from the first page to the last. Jenny June is the present editor, and subscriptions can be sent to the publishers at 44 East Fourteenth street, New York City.

RUSH MEDICAL COLLEGE, of Chicago, opened on September 30. Prof. J. H. Etheridge gave the address. He demonstrated his ability to smite the spike on the mathematical center of its cranial extremity by remarking that there were no easy spots in the life of a doctor. The class numbers about five hundred, nearly one hundred more than at the beginning of last term.

AT the opening exercises of the Philadelphia Dental College, Cherry street, below Eighteenth, addresses were delivered by Profs. James E. Garretson, E. E. Montgomery, J. Foster Flagg, S. H. Guilford, Henry I. Dorr, Dr. James W. White, editor of the *Dental Cosmos*, and others. There was a large attendance of students, both of the Medical and the Dental Colleges.

ONE of Reed & Carnrick's extensive factories at Goshen, N. Y., was destroyed by fire on the 10th inst. This factory was devoted wholly to the production of their Soluble Food and Lacto-Preparata, and contained extensive and valuable machinery. They had considerable stock of these Foods at their New York office, and consequently there will be no delay in filling orders. The factory will be at once rebuilt three times the size of the one burned, with machinery correspondingly enlarged.—*Dietetic Gazette.*

SEI-I-KWAI reports that between July 3 and 18, there were 1,927 cases of cholera at Nagasaki, and 1,029 deaths. Tokyo, with a population of 1,629,820, reported, in four weeks of December, 1889, deaths numbering 2,254—a rate of 18.07 per 1,000. The principal causes of death were meningitis, apoplexy, phthisis, and gastritis; followed by old age, pneumonia, and infantile convulsions.

DIPHTHERIA has broken out in the Good Intent School in Newton township, Bucks county, Pa. Dr. E. H. Doan examined the building and found the drainage pipe from the washing sink stopped up, and much dampness and decay in the cellar. Repairs were made and the school room disinfected and closed for a few days. When opened again most of the scholars were afraid to come back.

QUINOLINEPARAMETHENYLBENZENYLAZOXIMEPARACARBOXYLIC ACID is *Quinolineparamethenyluramidoxime and phthalic anhydride* melted together.

All this to the vulgar mind seems but a circumlocutory and pleonastic cycle of superfluous hyperscientific sonorosity circumscribing an atom of chemical ideality, lost in a verbal profundity.

—*Medical Mirror.*

THERE are a few things that the fair sex are supposed to know far more about than the men do; but sometimes this proves to be a mistake. A writer in the *Covert Medical News* tells of being sent for in hot haste to attend a lady in confinement. The usual inquiries were put, showing that there were no indications of parturition, except a conviction on the lady's part that her time was up. Examination revealed the further unimportant fact that she wasn't even pregnant.

A DOUBLE-HEADED snake of the moccasin variety has just been brought to Galena, Ill., by a party of fishermen, who killed the monster near the water's edge of the cut-off, about three miles distance from the city. Its length was little short of five feet, and its circumference around the thickest part of its body being eight inches. The kind of bait used by this party is not advertised in the columns of THE TIMES AND REGISTER.

THE J. M. Da Costa Society held its first meeting of the season at the office of Dr. Ludwig Loeb, 889 North Sixth street. Dr. Loeb read a paper on Nephritis, and Mr. J. Schamberg presented on the microscope several interesting pathological specimens illustrating the morbid changes. The next meeting of the society will be held at the office of Dr. Dillon Drake, 925 Pine street. Papers will be read by Drs. Dillon Drake and Carl Weiland, on Croup and Diphtheria.

THE report of the State Board of Health as to the number of registered medical practitioners in Pennsylvania has just been issued by the State Board of Health. There are 9,318 practitioners, of whom 641 are of foreign birth. Every nation, with the exceptian of Spain, is represented in this State's medical practitioners. In Bradford county, the law requiring registration seems to have been neglected, but two physicians being registered. This gives 17,464 persons to each physician. This condition also exists in Lehigh county, where but twelve physicians were reported, making 5,497 persons to each one. In Forest county the largest number of registered physicians can be found in proportion to the population.

THE *London Spectator* contains an account of Mr. E. T. Chaplin, who hypnotized a laying hen, which, without any predisposition in that direction, was made to sit on a sitting of eggs until seven of them were hatched into "healthy, happy little chickens." Well, when hypnotism has advanced far enough so that an egg may be hypnotized into a chicken without the offices of a sitting hen, then we will begin to see some of the practical worth of this mental phenomenon.—*Sanitary News.*

THE wholesale druggists in convention assembled elected the following officers for next year: Daniel Stewart, of Indianapolis, Ind., President; R. W. Powers, of Richmond, Va., Robert Shoemaker, of Philadelphia, T. F. Main, of New York, and E. C. Frisby, of Cleveland, O., Vice-Presidents; S. M. Strong, of Cleveland, O., Treasurer, and A. B. Merriam, of Minneapolis, Minn., Secretary. They also resolved that they never, no never, would sell the retailer less than a quarter dozen at wholesale prices.

A PECULIAR accident occurred in the establishment of Messrs. William H. Hoskins & Co.'s stationery establishment, Chestnut street, Philadelphia, by which Miss Mary Armstrong nearly lost her life. Her long hair became caught in a vertical shaft, and in an instant she was whirled around over one hundred times before the machinery could be stopped, when it was found that she had sustained a fracture to one of her hips, and that her scalp was almost torn off. She was removed to the Pennsylvania Hospital.

A PARISIAN lady, Miss de Broen, is conducting a medical mission in Belleville that is without a parallel in the history of medicine or religion. The little iron chapel-like building is built on the spot where a number of communists were shot down after the peace of the Franco-Prussian war had been proclaimed. The patients assemble in the pretty little chapel, and while waiting their turn to enter the adjoining dispensary, listen to sweet music played on the organ by a volunteer. Advice and medicine are given by the house physician, and no fee is charged.

"SOMETIMES when a woman loses her waist line and finds it difficult to lace her shoes," says a writer in the Chicago *Inter-Ocean*, "she deserves sympathy, but when she becomes the victim of a banting system she is entitled to pity. Superfluous flesh is a dangerous thing to experiment with; it can be worked down, run down, and even walked down, but to resort to drugs is to lay up a grudge that nature will unquestionably avenge." "'Exercise, exercise, exercise,' should be the stout woman's motto. Don't starve yourself, but diet a little and watch the effect of your food."

THE Northwest Branch of the Y. M. C. A. of Philadelphia have opened a course of Medical Talks, for the Thursday evenings of October, at 1518 Columbia avenue.

The subjects are as follows:

October 2.—"Facts Worth Knowing," by L. Harrison Mettler, M.D.

October 9.—"Physical Exercise," by J. M. Anders, M.D.

October 16.—"The Brain," by H. C. Deaver, M.D.

October 23.—"What to do in Emergencies," by L. Ott, M.D.

October 30.—"The Development of the Human Frame," by T. Ridgway Barker, M.D.

ZELIE BOURRION, the fasting girl of Bourdeilles, in the department of the Dordogne, who endeavored to emulate the feats of Tanner, Succi, and Jacques, has just died at her home. Her constitution was completely shattered after her fast of thirty-three days. When she returned to her cottage, she tried to eat a little, but her stomach was unable to bear the food, and she succumbed in a few days. Her fate will serve as a warning to any persons of her sex and class who may have been tempted by the notoriety which she obtained by her fast to follow in her footsteps.—*Hospital Gazette.*

FROM the *Ledger* we clip the following note concerning one of our old and valued advertisers: "The addition to Henry K. Wampole & Co.'s wholesale drug plant, at 441 Green street, is nearly ready for occupancy. It fronts on Lynd street, back of the old building. It is twenty-two feet wide by fifty feet long, and four stories high, making, with the old structure, a building twenty-two feet wide and one hundred and fifty feet deep. The addition will be supplied with all the latest appliances for preparing the different specialties of the firm. The firm has had to make several enlargements recently."

THE Board of Managers of the Germantown Hospital have just issued an appeal for help. The hospital is growing in importance and its scope of usefulness is increasing. While the yearly expenses of the institution have in the past five years increased nearly twofold, the receipts have not increased in the same ratio; consequently, to meet current expenses, the permanent fund has been drawn upon to the extent of nine thousand dollars. The hospital is free to all, and supported entirely by voluntary contributions. Contributions may be sent to the treasurer, Joseph M. Shoemaker, Drexel Building, or Locust avenue, Germantown.

CHICAGO, having won the World's Fair, must submit to innumerable jokes and jokelets, and unkind predictions of failure, coming from disappointed competitors. We trust that none of our readers will make the mistake of taking these things seriously. Chicago will hold the Fair, and put into it all of that prodigious energy that has made Chicago what she is. If our judgment goes for anything, the World's Fair of 1892 will eclipse everything of the sort that has preceded it. We hope and believe that the Centennial Exposition will be so greatly excelled that foreign visitors can form some adequate conception of the great material advances made by the country since 1876.

WE often have to laugh at the absurb way in which the lay journals get mixed up over medical affairs, but what are we to think of the following, from the *Medical Standard*, of Chicago:

Philadelphia.—There is a row eminently disgraceful to Mayor Fitler, of "Fitler's Rheumatic Remedy" fame, and the State Board of Charities, anent the treatment of the insane in Blockley Almshouse. The mayor has been using the almshouse as a political machine.

There are a few trifling inaccuracies in the item. 1. There is no "row" over the treatment of the insane in Blockley Almshouse. 2. Mayor Fitler is not of "Fitler's Rheumatic Remedy." 3. The Mayor has not been using the almshouse as a political machine. With these exceptions the item is correct. Brother Kiernan had better "verify his references" when he gives Philadelphia news hereafter.

LIVING BY RULE.—Oliver Wendell Holmes thinks that he owes his good health and the retention of his mental vigor in his eighty-first year to the extreme care he has long taken of himself. Never robust, he was still wiry in his earlier and maturer life; but since he reached eighty, his hygienic vigilance is unceasing. The rooms that he daily occupies are equipped with barometers, thermometers, aerometers, every kind of instruments, in short, to prevent his incurring the slightest risk of taking cold. He knows that pneumonia is the most formidable foe of old age, and he is determined to keep it at a distance, if possible. He never gets up until he knows the exact temperature, during winter, or takes his bath without having the water accurately tested. He lives by rule, and the rule is inflexible. His time is scrupulously divided: so much allotted to reading, so much to writing, so much to exercise, so much to recreation. His meals are studies of prudence and digestion. He understands the specific qualities of all ordinary foods, and never departs from the severest discretion in eating.

THE result of seven years' operation of Medical Practice Acts in Minnesota has been to reduce the ratio of physicians to population from 1 to 650 to 1 to 1,250. Hundreds of charlatans have been driven over to Michigan and other unprotected States. In comparing the proportion of physicians in Minnesota to that existing in European countries like France and Italy, it must be borne in mind that, where the population is scattered, the work is far greater than when people are closely packed in thickly populated districts. It is doubtful if one man can attend 1,250 people as easily in Minnesota as he could 3,500 in Italy.

The present law has been in operation for three years, and in that time 205 candidates presented themselves, and 77 of these were rejected. Many other incompetents were doubtless deterred from presenting themselves by the fear of rejection. The Examining Board has conferred a priceless boon upon the citizens of Minnesota, and its appeal for support and co-operation from the physicians of the State should be universally responded to.—*N. W. Lancet.*

CHICAGO MEDICAL COLLEGES.—The medical colleges of the city announce, without exception, a great increase in students this year. They are all now open. They have had prayer and speech in their inauguration ceremonies. They assume an air of dignity and gravity in beginning the year's work. It was said of old that two priests of pagan Rome could not meet without laughing in each other's face. The faculties of these medical colleges must be disposed to follow the pagan priests' example. But they probably do the laughing in private.

For it is well-known that they have received this year, as they have received every year, students who should not have been admitted to the study of medicine, or to the sham which the study of medicine amounts to under the conditions tolerated in these colleges. They have now in their class rooms illiterate men and women whose educational foundation would not fit them for good salesmen or women, or book-keepers, or teachers of the elementary branches of the English language. The professors in these medical schools know this to be true. They are in a conventionalized conspiracy to keep up the fraud solely for the fees, and, indirectly, for the imaginary fame individual colleges are supposed to possess.

It is true that they all now go through the mock

ceremony of requiring certificate of academic education, or, in lieu of it, examination with satisfactory results. *The Herald* would be pleased to receive copies of the examination papers made out by students before admission to any medical college in the city, or authentic proof that a practical test of any nature whatever has been imposed upon applicants as an indispensable condition of matriculation. It is amazing that men who would scorn to make money in commerce dishonestly are willing, or at least passive, while it is made with substantial dishonesty in the pretended medical education of the time, not in Chicago only, but in most of the medical colleges in the country. Of the 700 men and women now studying medicine in Chicago probably not one-fourth have had any general education deserving the name.

—*Chicago Hearld.*

THE following extract from a drug journal we earnestly commend to the physician who votes in societies for higher medical education, and then sends his students to the "cheapest and easiest" college he can find. With a little alteration, the shoe will fit him nicely.

"Gentle reader, come with me now and gaze into yonder modern pharmacy. Behind its polished French plate-glass window, before a tower of marble with silver faucets, we behold a gentleman clad in white, airy clothes, shaking his eggs and phosphating milk, slashing around ice-cream and squeezing lemons so they will go through a straw. Is this a dream? Did not you and I see this man last year, at this and that meeting, clad in broadcloth, adorned with a half-yard of crimson satin badge, delegate of such and such association? Did he not take the meeting by storm with his eloquent appeal for the highest possible scientific education? He insisted on three terms at college, made analytical chemistry mandatory, and counseled the compulsory study of microscopy, so that even the registered assistant could readily tell by his lens whether the specimen before him was a horizontal cut from the Canada snake-root or the head of a family tape-worm. Aye! it is he—a genuine Ph. G. At the meeting, the scientific tribune; at the pharmacy, the temperance bar-keeper. Are you in a mood to answer the question, 'Is Pharmacy a Profession?' Who hallooed 'Rats!' way up in the balcony?"

MEDICO-CHIRURGICAL HOSPITAL.—*Enlargement of the Scope of this Useful Institution.*—Owing to the delay in completing the rebuilding of the Medico-Chirurgical Hospital, the managers have been compelled to provide temporary accommodation for their patients. With this object they have transferred the dispensary service to the college building, and have arranged the rooms previously occupied by the dispensaries into wards for surgical and emergency cases. As an Annex for medical and convalescent cases the property on the southeast corner of Seventeenth and Summer streets has been secured.

This building also contains the matrons' and nurses' apartments, and a resident physician is stationed at each building. The two buildings will accommodate thirty-five patients, and, although they have been open but one week, more than half the beds are occupied.

The necessity of a hospital is shown by the fact that, during the two months when the hospital was closed, a number of accident cases were turned away, and one came in on the day of opening before the beds had been set up. In addition to a number of injuries treated and sent to their houses, three serious cases were taken into the wards, each of which would have been seriously endangered by transferring them to more distant hospitals. The demands on the managers are numerous, and supplies of all kinds are needed. Contributions may be sent to the Annex, Seventeenth and Summer streets. The ambulance is ready for duty at all hours.

THE following articles are affected by the new tariff bill. The first figures give the old tariff, the others the new:

Acetic acid not exceeding 1,047 specific gravity, 1½ cents a pound; 2 cents.
Boracic acid, 5 cents a pound; 4 cents for commercial.
Chromic acid, 10 cents; 15 per cent.
Sulphuric acid, ¼ cent a pound; free.
Tannin, 75 cents; $1.
Carbonate of ammonia, 1¾ cents; 20 per cent.
Muriate of ammonia, ¾ cents; 10 per cent.
Sulphate of ammonia, ½ cent; 20 per cent.
Blue vitriol, 2 cents; 3 cents.
Chloroform, 25 cents a pound; 50 cents.
Sulphuric ether, 40 cents; 50 cents.
Nitrous ether, 25 cents; 30 cents.
Crude glycerine, 1¾ cents; 2 cents.
Refined glycerine, 4½ cents; 5 cents.
Iodoform, $1.50; $2.
Licorice, 5½ cents; 7 cents.
Carbonate of magnesia, 4 cents; 5 cents.
Calcined magnesia, 8 cents; 10 cents.
Epsom salts, 3-10 cent; 12 cents.
Morphia, 50 cents an ounce; $1.
Cod-liver oil, 15 cents a gallon; 25 per cent.
Cottonseed oil, 10 cents; 25 cents.
Croton oil, 30 cents a pound; 50 cents.
Flax or poppy-seed oil, 32 cents a gallon; 25 cents. Poppy-seed oil free.
Olive oil, 25 cents a gallon; 25 per cent.
Peppermint oil, 80 cents a pound; 25 per cent.
Fish oil, 8 cents a gallon; 25 per cent.
Opium containing less than 9 per cent. of morphia and opium prepared for smoking, $12 a pound; $10 a pound. The old law prohibited importation of opium containing less than 9 per cent. morphia; containing more than that, crude, $1 a pound.
Phosphorus, 20 cents; 10 cents.
Caustic, 1 cent; 20 per cent.
Saltpeter, 1 cent; 1½ cents.
Mercurial medicinal preparations, 35 per cent; 50 per cent.
Santonine and salts containing over 80 per cent. of santonine, $2.50 a pound; $3.
Sulphate of soda, $1.25 a ton; 20 per cent.
Strychnine, 40 cents an ounce; 50 cents.
Refined sulphur, $8 a ton; $20.
Flowers of sulphur, $10 a ton; $20.

THE BRANCHES OF THE EDITORIAL PROFESSION.—We clip the following from the Kansas City *Medical Index*, edited by Emory Lamphear, the Universal Specialist of Kansas City, who has some ability, much bad taste, and great energy which is misdirected:

There is more than one branch of the editorial profession. As witness the following conversation:

Stranger: "Ah! If I mistake not this is Dr. Hate, of the *Medical 'Looking-glass,'* is it not?"

Dr. Hate: "Yes, that is my name."

Stranger: "Well—I'm very happy to meet a fellow-journalist."

Dr. Hate: "But really I do not remember you—"

Stranger: "Indeed? Why I'm the man who writes the *patent medicine testimonials* for Merrell's Almanac!"

The cheap wit in the little item quoted can be better understood after the reading of a little incident which occurred at the recent meeting of the Missouri State Medical Society at Excelsior Springs, Mo.

Scene: The Elms. A party of gentlemen engaged in social conversation interrupted by the following:

Emory Lamphear: "Dr. Love, how much did you get for writing the commendatory article for Mellier's Ponca Compound in the last number of the *Mirror?*"

Dr. Love: "Not one cent; however, Mr. Mellier is present, you may ask him."

Mr. Mellier: "Dr. Love received nothing for the article referred to."

Dr. Lamphear: "Dr. Love, that seems odd. An article of that kind could not have appeared in the

Medical Index except for money. I run the *Index* for money."

Dr. Love: "Dr. Lamphear, nothing can appear in the advertising columns of my journal announcing a pharmaceutical product which I know to be objectionable. If I find a compound is of value, having clinical experience, I shall not hesitate to say so, believing the information to be of value to the profession.

"If the article happens to be advertised in my journal and my advertisers are benefited, I am glad, but the commendation will be made, if justified, without reference to whether it represents an advertisement or not.

"No living man ever secured a commendation from me for anything by the payment of money. The suggestion of such a thing, if coming from the proper source, would be resented as an insult.

"The difference between the *Medical Mirror* and the *Medical Index*, from your statement of the case, is that the *Medical Mirror* likes to say kind things in general, and particularly of its friends, even though those friends be advertisers.

"The *Medical Index* rarely has kind words, and none except for money."

Yes, there is more than one branch of the editorial profession.— *Medical Mirror.*

BOTH the Doctor and his wife, Mrs. S. S. Stryker, of Thirty-ninth and Walnut streets, were made quite ill by something they had eaten at the "barn party" of Mrs. Washington A. Roebling, at Trenton, a week ago last Friday. Both, however, have since fully recovered.

THE Protestant Hospital for Insane in Montreal has been formally opened, and thirty persons were admitted up to the end of August. Dr. Burgess, so well and so favorably known in Ontario, was appointed superintendent. He is now in charge of the institution. The *Montreal Medical Journal* expresses the hope that "in a year or so it will rank among the foremost of our American asylums, for the beauty of its surroundings and the good results accomplished."

AMONG the names of those applying for a charter for the National Women's Health Association of America, whose purpose is to teach each other and the public generally the laws in relation to health, may be found those of Drs. Caroline M. Dodson, Mary J. Scarlett Dixon, A. Victoria Scott, Mary Brauson, Harriet S. French, Sarah T. Cohen, Charlotte Y. Olsen, Mary B. Werner, E. Warrington Rockwood, Phila M. Brink, Ella Ridgeway Ziegler, Josephine Van Deusen and Sarah T. Rodgers.

DOCTORS' BILLS.—*Editor of The Herald:* Please inform me: 1. Can a doctor collect a bill if he is called in for a case of poisoning? 2. After doctoring a person in limited circumstances how long do they generally wait for payments? READER.

[1. Of course he can. Doctors don't practice medicine for fun. Isn't he just as much entitled to his fee for saving a man's life as a lawyer is for saving his neck from the gallows? 2. They wait a reasonable time,

"It may be for years
And it may be forever,"

with the hope of getting their reward in the next world. Most people pay the doctor's bill after they have paid the butcher and the tailor and the cigar man and the saloonkeeper. Meanwhile the doctor is expected to live on wind and promises on toast.]

—*Chicago Herald.*

NEW PATENTS, ETC:—

PATENTS ISSUED SEPTEMBER 30, 1890.

Atomizer	R. W. Coffee	Bedford City, Va.
Sulphur candle	C H. Shaw	Brooklyn, N. Y.
Dental engine	E. Thompson	San Francisco, Cal.
Reducing licorice-root, etc., to powder	S B. Rickerson	Toledo, O.
Remedy for asthma	Iselin & Callahan	Riverside, Cal.
Syringe	A. H. & M. G. Collins	Camden, N. J.

TRADE-MARKS ISSUED SEPTEMBER 30, 1890.

Remedy for diseases of the blood, liver and kidneys. (The figure of an eagle and shield, with the words :— "Dullam's Great German Remedy.")	Dullam Bros	Flint, Mich.
Mineral water. (The portrait of the registrant and his fac-simile signature.)	L. Janos	Buda-Pesth, Austria-Hungary.
Insecticide. (The word "Semi-nole")	Rumph & Carlile	Titusville, Pa.
Remedy for piles. (The portrait and signature of the registrant, "James McGarrity.")	J. McGarrity	Montreal, Canada.

LABELS ISSUED SEPTEMBER 30, 1890.

"Tonique-Amer. (de Savoie)"	T. Lamb	Newark, England.

LOCK BOX 76, WASHINGTON, D. C.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from September 24, 1890, to October 4, 1890.

In view of the early abandonment of Fort Elliott, Texas, to which post he is at present assigned for station, Major J. P. Kimball Surgeon, is relieved from duty at that post, and will, upon the expiration of his present sick-leave of absence, proceed to Fort Supply, Indian Territory, and report to the commanding officer for duty. S. O. 132, par. 2, Department of the Missouri, September 24, 1890.

In view of the abandonment of Fort Gibson, Indian Territory, to which post he is at present assigned for station, Captain W. O. Owen, Jr., Assistant-Surgeon, is relieved from duty at that post, and will, upon the expiration of his present leave of absence, proceed to Fort Sill, Oklahoma Territory, and report to the commanding officer for duty. S. O. 135, Department of the Missouri, St. Louis, Mo., September 27, 1890.

In view of the abandonment of Fort Crawford, Colo., to which post he is at present assigned for station, Captain J. S. Phillips, Assistant-Surgeon, is relieved from duty at that post, and will, upon the expiration of his present leave of absence, proceed to Fort Logan, Colo., and report to the commanding officer for duty. S. O. 135, par. 1, Department of the Missouri, St. Louis, Mo., September 27, 1890.

By direction of the Secretary of War, leave of absence granted Captain John L. Phillips, Assistant-Surgeon, in Special Orders No. 164, July 16, 1890, from this office, is extended two months. S. O. 228, par. 3, A. G. O., Washington, September 29, 1890.

Leave of absence for one month, to take effect about October 1, 1890, is granted Captain Louis H. Crampton, Assistant-Surgeon (Fort Sheridan, Illinois). S. O. 80, par. 2, Division of the Missouri, September 30, 1890.

PROMOTION.

MORRIS, EDWARD R., Assistant-Surgeon. September 17, 1890, to be Assistant-Surgeon, with the rank of Captain, in accordance with the act of June 23, 1874.

The Times and Register.

Vol. XXI, No. 16. NEW YORK AND PHILADELPHIA, OCTOBER 18, 1890. Whole No. 632.

Address.

THE NEW ERA IN MEDICINE AND ITS DEMANDS UPON THE PROFESSION AND THE COLLEGE.[1]

By W. W. KEEN, M.D.,

Professor of the Principles of Surgery and of Clinical Surgery, in the Jefferson Medical College.

ON the 8th of October, thirty years ago, I entered the lower lecture-room of the College building for the first time as a medical student, and listened to the Introductory Lecture. It was given by that phenomenal encyclopædia of knowledge, Robley Dunglison, for so many years the Dean and Professor of Physiology in this School. Time has gradually obliterated its then deep impressions, and now three memories alone remain to me. The first is the place where I sat; the second the precept, which has so often since then recurred to my mind in solving the medical problems which have presented themselves to me, that I must not confound the *post hoc* and the *propter hoc*, the sequence with the consequence; and the third was the gracious welcome which that fluent master of English gave to us, the incoming class.

It is my pleasant duty to-night to repeat, after a lapse of so many years, at least the same cordial welcome then extended to me—a welcome to you all, from North and from South, from the Atlantic and the Pacific, and even from far distant foreign shores. Nor is this welcome a merely formal one; it is heartfelt and true. Not only for myself, but on behalf of my colleagues of the Faculty, do I welcome you, as kindly and as earnestly as I possibly can, to the arduous study upon which some of you are about to enter; a welcome, quite as cordial, I also extend to those who have already trodden the thorny path of the first or second year of study, and who have now a better capacity to appreciate what they learn, and a better appreciation of the earnest efforts that will be made by every teacher of the school from the oldest of the Faculty to the latest acquisition among the assistants to the laboratories.

The welcome thus extended is saddened, however, by mournful memories. It is with feelings of deep respect and admiration that I refer, as is proper, to the teacher whose honored place I occupy, whose premature and unexpected death robbed the Jefferson College of one of its brightest ornaments; a man illustrious by his name, and not less honored for his own eminently useful scientific achievements. The warmth of admiration and affection which the older students among you bestowed upon the late Samuel W. Gross, was not ill bestowed, but was well deserved. Professionally he knew but one thing—Surgery. Even from his very entrance on his profession, this was his chosen department, and to it he devoted laborious days and studious nights. As a teacher he was incisive, progressive, well read, versatile, and accomplished. He was no uncertain and hesitating teacher, but gave you, in his own clear-cut and positive way, the best results of the foremost minds of the profession, both of this country and of Europe. Many of you can testify to his devotion to his subject, his students, and his Alma Mater. He sympathized with your joys, and helped you over the rough places with the utmost gladness. Few schools have had two such ornaments in one family as the elder and younger Gross; and in the midst of all the pleasure and hilarity of the opening of the session, it is meet and proper that we should pause a moment to lay a flower on the bier of each.

A moment ago I referred to the time when I myself began the study of medicine. You can scarcely appreciate what the study of medicine then meant, as compared with what it means to-day. About the time that I began, the custom had just ceased for each member of the Faculty to deliver an Introductory Lecture to his course each year. The session

[1] Introductory Address at the opening of the Sixty-sixth Annual Session of the Jefferson Medical College.

began on the second Monday in October, and the entire first week was given up by the Faculty to the daily Introductories, and by the students to more or less of revelry, as might become both their consciences and their purses. In the next week we settled down to greater or less regularity of life. The session continued until the end of February, and not a few men of the first year, like Charles Lamb, made up for coming late by going early. Examination over, the iron gate that used to guard the Tenth street entrance to the College swung heavily to, and was not opened again until the next October.

There were no laboratories. Apart from the seven classical branches there was absolutely no official instruction. No man was required to study physical diagnosis, or minor surgery, or chemistry, or the microscope, either in histology or morbid anatomy; and perhaps not a score of men in any graduating class had ever seen a muscular fiber cell, or striped muscular tissue, or a nerve cell, or a nerve tubule. The fortunate few who, in the offices of private preceptors, had a chance to give a wondering look from time to time through a microscope; to examine the urine for tube casts, or for any crystalline element, were equally small in number. Nor were there more who were ever taught to test the urine for albumin. The only histological reagents were acetic acid for clearing up a specimen, and carmine to color it, and the hand-held razor was the only microtome. There was no laboratory of physiology, no teaching of pathological anatomy, no instruction in pharmacy. Nor could any man properly write his first prescription, unless he had been privately taught by his quiz master or his preceptor. The only clinical instruction was in medicine and surgery, neither obstetrics, gynecology, nor any of the specialties being recognized. Indeed, a specialist was looked at askance, as a very questionable sort of doctor.

The seven months intervening between February and October were presumably spent with one's preceptor at home. How much each student would learn in that time, I leave you to judge as leniently as possible. During the spring and fall, however, there were open a few private lectures from voluntary associations of teachers, some of whom, now occupying honored places, I see about me. But these advantages were limited almost exclusively to the students who lived in the city. The examinations were easy, and for the disabled students an "omnibus" was prepared to carry them to, if not through, the perils of the "Green-room."

Contrast this with the opportunities that you have to-day. Every student has now the opportunity to become versed in bandaging, the application of fracture dressings, and the performance of all the ordinary surgical operations on the cadaver. All of you will have had some practice and careful clinical instruction in physical diagnosis. All of you will have attended lectures on pathology and have made a more or less careful personal study of both normal and diseased structures with the microscope. All of you will have passed through the laboratories of physiology, of materia medica, of experimental therapeutics, of pharmacy, of chemistry, and have studied especially the chemistry of the urine and other secretions and excretions of the body. All of you will have had careful instruction in practical obstetrics, in obstetrical examinations, and gynecological operations. All of you will also have had instruction in diseases of the eye, the ear, the throat, the nose, in electricity, toxicology, orthopedics, diseases of the skin, diseases of children, and insanity, not one of which at that time was officially taught in this or in any other medical college.

This immense change smacks almost of revolution. But there is need of a new and fresh overturning. The last few years have seen such rapid movement and progress in every department of medicine that we stand practically in a "New Era in Medicine," and the new era makes new demands both upon medical colleges and the medical profession to which, if we be blind, we shall be derelict in our duty, both to ourselves and the public.

Let us for a moment take a bird's eye view of these changes. First of all a wholly new department of medical science, Bacteriology, has been created. Rejected at first by most, and only doubtfully and hesitatingly believed in by many, except some prophets of the dawn endowed with finer vision than the rest, it has achieved within the last ten years a positive and now practically unquestioned place in medical science. Its revelation of the causes of many diseases and its explanation of their phenomena are as startling as they are well substantiated. That suppuration and erysipelas, tetanus and leprosy, consumption and cholera are parasitic diseases due to the invasion of the body by various forms of micro-organisms is a discovery of the first importance, and much too near as yet for us to appreciate its far-reaching influence. It has but begun its infant career. It must speedily grow into one of the most weighty of the scientific departments of medicine, and bids fair to revolutionize our practice as much as it has our theories.

The old Materia Medica and Therapeutics have been rewritten within the last few years in the Pharmacology of the present day. The actual daily use of medicine has been marvelously changed of late by experiments made to discover the real physiological and therapeutical action of remedies; their effects upon the heart, the arteries, the brain, the respiration, the kidneys; their medicinal and their toxic doses and effects; and from these facts to deduce a right and rational use of drugs. Besides this the extraordinary number of new drugs and the numberless new methods of their administration, the present scientific use of massage and of electricity in its various forms, the increasing use of Swedish movements, of heat, of cold, of mechanical means for soothing and stimulating nerves and muscles, and for spinal extension are all additions of the last few years.

Allied to this there is virtually a "New Chemistry," not only in the sense in which the term is used by Prof. Cook. Organic chemistry has by its analytic methods given us many of the new drugs already alluded to, and by its synthetical combinations has even produced them in the laboratory instead of waiting for Nature's slow distillation by long growth; and has by its substitution compounds given us different series of remedies of immense value, all built upon a single base.[1]

Chemistry and pharmacology, with physiological physics, embryology, and experimental physiology, have developed a new Physiology.

Even Anatomy, a field of stubble scarce worth a gleaner's searching eye as was supposed by many, has rewarded the industrious toiler by rich and full sheaves. Even in gross anatomy, to name no other, the mapping of the convolutions of the brain, and determining their functions, by Ferrier, Horsley, and

[1] If any one doubt the existence of a new-visaged and promising chemistry and pharmacology, let him only read the recent lectures of Dr. Lauder Brunton, in the British Medical Journal, On the Relation between Chemical Composition and Physiological Action.

others; the study of surface anatomy in its relations to the interior, by Holden; the careful study of the intestinal canal by Treves, have been of immense service: while embryology and histology and comparative anatomy have reformed a large part of the science.

These scientific departments are the foundation upon which are built surgery, medicine, obstetrics, and gynecology, the practical departments of the healing art. These, too, like Samson of old, have burst the withs and ropes of the past and risen up in renewed strength, and have gone forth conquering and to conquer.

In Surgery and Gynecology the effects of experiments upon animals, of bacteriological studies, and of the antiseptic method, have been almost past belief. The mortality of amputations has been reduced from twenty-five to fifty per cent. down to from four per cent. to zero, and compound fractures, instead of yielding a holocaust of fifty to sixty per cent., are now, if rightly treated, scarcely more dangerous than simple fractures. The abdomen, instead of being forbidden ground like the lost Eden, with the peritoneum for its "flaming sword which turned every way to keep the way of the tree of life," might almost be called a playground in which surgeons disport themselves to their heart's content, inventing new operations as children invent new games; not an organ contained in its once sacred interior, or in that of the pelvis, is free from attack, and for the most part, happily, with as great relief to the patient as pride to the surgeon. The brain, till five years ago the most dreaded organ in the body, is now not only freely exposed without serious danger, but portions of it excised, abscesses opened, the ventricles irrigated, and tumors removed. Bones are sawn or wired; joints are opened; the chest is invaded, and the lungs are resected. These and other operations successfully done are witnesses to the new era in general surgery[1] and gynecology, while in each special branch of surgery the same could be shown to be true had I only the time.

In Medicine and Obstetrics the same progress is noted in newer and better treatment of many of the ordinary diseases and the usual obstetric conditions. The diminution of the mortality rates is simply extraordinary; and often the new methods of treatment are as simple and grateful as they are successful. To name but one department of each: Our acquaintance with diseases of the nervous system has grown so rapidly that a text-book of thirty years ago is apt to elbow Galen and Avicenna for sympathy in its neglect, while the mortality of the puerperal state has been reduced by the introduction of antiseptics almost to a vanishing point.

Of the many specialties in medicine I cannot take time to speak, save to note the fact that they all have been created or remodeled within the last twenty years.

In view of these facts, am I not justified in calling this "The New Era in Medical Science?"

It will be the duty, the privilege, and the joy of the teachers in this flourishing and progressive school of medicine to give to you the details of this fascinating medical romance in the course we are now entering upon, and I envy you the privilege of engaging in this study thirty years later than I. I have not used the word "faculty," but "teachers;" first, because I wish to recognize and I wish you to recognize the worth and zeal of the junior teachers associated with us, both in the college and the hospital; younger men who freely give of their time to aid you, and largely for the pure love of science. The best and highest reward that ever comes to them, as to us, or to any mortal, is the inward glow and satisfaction of good work done in scientific research, of an enlargement of the domain of truth, be it ever so little. "I labor less," said Fresnel, "to catch the suffrages of the public than to obtain that inward approval which has always been the sweetest reward of my efforts. Without doubt, in moments of disgust and discouragement, I have often needed the spur of vanity or emolument to excite me to my researches. But all the compliments I have ever received from Arago, de la Place, or Biot, never gave me such large pleasure as the discovery of a theoretic truth or the confirmation of a calculation by experiment."

The word "teacher" also designates us all as members of one of the noblest guilds in the world. For twenty-four years I have also myself glorified in the name and work of a teacher, and desire no better title. It is said that when Agassiz's will was opened it ignored all his other proud titles and began majestically "I, Louis Agassiz, teacher . . ."

The new era in medicine so inadequately described now confronts the profession, and especially you, gentlemen, who are to practice it, and whose lives will be spent, remember, among the glories of the twentieth century, with the now undreamed of progress of that happy time. It confronts you as a mighty master, with uplifted hand, pointing you upward and onward; onward to the laborious but great and splendid work awaiting your touch, and upward to the prizes for the foremost and worthiest. But it makes also its demands, its inexorable demands upon you. Satisfy them you must, or fail.

Let us look for a few minutes at what these demands upon the profession are.

A physician's life consists of three periods; corresponding to those of his preliminary education, his medical college course, and his active life as a practitioner. These may be called the Pre-collegiate, the Collegiate, and the Post-collegiate periods, and I purpose speaking in a plain and practical way of each.

1. The Pre-collegiate period, or that of preliminary training.

The ideal medical college would perhaps insist that this be nothing short of a complete liberal education, such as is given in our American colleges and universities, and it is an encouraging feature of the times that the proportion of such college graduates now in our medical schools is steadily on the increase, and that one of our numerous medical societies is composed wholly of those who have received not only the degree in medicine, but that in arts as well. Native talent and hard work will always tell, but such talent when trained and set at work will accomplish vastly more. But this is a world of imperfections and limitations in which the Utopia of the ideal-best must give place to the cold matter-of-fact attainable-best. Desirable as it might be that all of the profession should have such a complete preliminary training, we all acknowledge it to be impossible, at least at present. But such a preliminary education as would at least fit a man to enter the freshman class at our ordinary colleges before many years past must be, in my opinion, a pre-requisite to the study of so wide, so progressive, so logical, and so exacting a science as medicine as it now exists. If necessary to fit a man to study the ordinary college branches, it would seem *a fortiori* to

[1] I have given in a popular form a fuller account of this Recent Progress of Surgery, in *Harper's Magazine* for Oct., 1889.

be necessary for such technical study. Even this we cannot expect at once. But it must be the goal toward which we must strive. I congratulate you and the Jefferson College most heartily on the inauguration this ye r of an entrance examination—a real, though a moderate one—a beginning that is but a herald, I hope, of more exacting examinations in the future, as thus we grow up to our privileges and opportunities. Moreover I must not forget that I am addressing those who have concluded this first period, and who have already entered, or are about to enter, upon the second. Those of you who have had a complete preliminary training I congratulate, and at the same time I remind you that more is to be expected and exacted from you than from others. Should you pride yourselves upon the privilege and relax your efforts in the least degree, remember that the tortoise once beat the hare, and can do it again.

To those of you that have not had such a preliminary training, the question arises, What shall you do? Recognize honestly the defect and go to work manfully to make up for it just as far and as fast as you can. You can do but little of this, perhaps, during your college course. In the winter you will have no time, and I feel chary of your using your summer holidays for much hard work. But if not now, then so soon as you graduate, when your conspicuous patients—conspicuous by reason of their rarity—leave you plenty of unasked for leisure, then you must begin with zeal to complete such a desirable education. But more of this hereafter.

2. The collegiate period, or that spent in a medical college.

I will not spend time in a repetition of the trite maxims inculcating due diligence, hard work, regular attendance, close attention, and all that. You were once boys who needed mental and possibly even corporal flagellation. But you are past that period, and are now young men. Not that you have outgrown the need for these virtues, but that we take it for granted that you have them and will use them. We have no rules and no roll call for these very reasons. You are placed upon your honor to do your very "level best." "Education," it has been wittily said, "is the only thing in which we try to get the least for our money." It is for you to prove its falsity.

In the brief time you will spend here we can tell you but little of the immense array of facts in medicine. You will learn much it is true; but compared with what you do *not* know, what you *will* know when you graduate will be as nothing. The chief services of a medical college are twofold. First, it will give you the great principles that underlie each department, with the main facts that prove them. But secondly, and if possible even more important, it will give you an impetus in the right direction. The use of a cannon is to compel the ball to follow its proper path. The gun is but a few feet long but the impetus and guidance it gives in those few feet are unalterable. The huge missile follows its course to its goal. If the gun is aimed low its path will be low and its goal will be near; but if the aim be high it will cover miles in its course and triumphantly strike its distant target. Enter then here into the enthusiasm of the place and the time. Catch the scientific spirit pervading the very atmosphere of the place. Let it permeate every fiber of your mental structure. Let it be your meat and drink, your very life. This short period is to give you the "bent," "the set," the "curve" of your whole later professional life. See to it that you use it well.

Remember, however, that while we can "teach," it is you that must "learn." We can but spread the rich feast. It is you who must eat and assimilate it. We give "instruction,' you must transfer it into an "education," and make it an abiding possession. "Pray, Mr. Opie," said a visitor to the artist, "what do you mix your colors with?" "With brains, sir," was the brief but pregnant answer.

But while inculcating all this diligence and enthusiasm let me caution you to see to it that your health does not suffer; not perhaps from too much work, but rather from unwise methods of work. The daily bath and a proper amount of exercise will go far to counteract the bad air of the lecture and dissecting rooms. Get to bed early; then you know you can get up early, which you all so much long for. Study none on Sunday. Being medical students does not release you from the moral and religious duties and pleasures of the Sabbath—the day of rest—here any more than at home; and a complete change in the current of your thoughts is no less refreshing than it is physiological. One of the worst evils of our present system of education is cramming for examination. A reasonable review of bygone lectures is wise and useful, but cramming is quite another thing. It means that you have been lazy and derelict during the winter, and to make up for lost time, you ram and cram your heads full of a mass of unassimilated facts to dole them out parrot-like to the too inquisitive professor. I cannot better present its evils than by quoting from that wise old Grecian Epictetus, for it seems to be a very hoary vice: "It is," says he, "as if sheep after they have been feeding, should present their shepherds with the very grass itself which they had cropped and swallowed to show how much they had eaten, instead of concocting it into wool and milk." Next April, remember, we don't want the "grass," but the "wool and milk."

You will learn the use of many new and valuable instruments: The microscope, otoscope, ophthalmoscope, laryngoscope, and all other "scopes;" the many specula, aural, oral, nasal, vaginal, rectal; many beautiful and useful refinements in chemical reactions and in pathological appearances, all useful as means of diagnosis. You must master them all. They are the tools of your profession. If you miss learning their use now you may never again have the chance. In the remote West, in a small country village in the East, or elsewhere, you will sometimes sorely need them, when you will have no willing professor or quiz master to whom you may appeal. They will help you in a multitude of cases, and often are simply indispensable.

But I want to urge you to do one thing more; to combine with all of our nineteenth-century inventions, eighteenth-century shrewdness of observation, and acute cultivation of the normal, unassisted senses, in order to make up the more perfect doctors of the twentieth century. If you have not read "Spare Hours," by the lovable and accomplished Dr. John Brown, of Edinburgh, the author of "Rab and His Friends," that most charming medical story, you have a treat before you. Some pages are more succulent than others, but there is not a sterile patch among them. In the third series you will find most of the medical papers, and they are bracing reading for a doctor. I know nowhere a stronger plea for this very education of the senses which I wish to urge upon you. As there were heroes before Agamemnon, so eyes and ears existed before oxygen was known or Laennec lived, and our forefathers had sharp eyes, shrewdly hearing ears, and delicate fingers that had

to take the place of the specula and the scopes of our day. "Every fellow," says the blind but knowing master of wood-craft, in Dr. S. Weir Mitchell's last story, "every fellow ought to be blind ten years, and deaf ten more, and then get his eyes and ears. He'd know a heap, I tell you he would."

Medicine is not a deductive science. We do not start from *a priori* principles and reason to conclusions. It is intensely inductive. We collect our facts, the more the better, as increasing numbers diminish the ever possible chances of error, we collate them in orderly sequence, and gradually rise from facts to principles. Hence if our facts are badly observed, our principles are sure to be erroneous.

I am persuaded that the chief source of errors in diagnosis is not want of knowledge, but careless or insufficient examination into the facts of the disease. I have seen a diagnosis of rheumatism of the knee joint, in a case in which lifting the knee two inches from the bed instantly showed the crepitus from a spontaneous fracture following long existing osteomyelitis. I have been called to a case of hemorrhoids which a glance and a touch resolved into an ischiorectal abscess; and I have seen days of uncertainty and groping for a diagnosis cut short by a few taps over the back of the lungs that revealed an unsuspected pneumonia. Had the leg been once lifted, the perineum inspected and touched, the posterior chest examined—two minutes only, but two minutes of exactness—no such errors would have occurred.

The eye must be taught to take in much for which no speculum is needful. The physiognomy of the patient, the modes of expression, whether facial or vocal, spontaneously assumed postures of the body, tremulous or steady movements, the color, the breathing both as to frequency and character; the outlines of the body, normal or abnormal; the exact relations of parts; all these, and a hundred more, all stand with their cup of information filled to the brim for him who will drink. The ear may be aided by the stethoscope, but it must not be trammeled by it. It must be trained to abnormal alertness, and hear every sound, from the normal loud gurgling of the intestines to the faintest suggestion of it while using taxis in a hernia; from the loud tubular breathing of a widespread pneumonia, to the judicious discrimination of the relative respiratory murmur in the apices. The touch, though it can scarcely be educated up to the standard of Laura Bridgman, can give you the needful facts as to hardness, softness, elasticity, resistance, contour, crepitus, and the like, if you will but use it. No instrument can replace it. Let your fingers therefore itch till you have touched and felt every case that by hook or by crook you can lay your hands on. Smell and taste are not seldom called into play, and here at least we can use no artificial helps. Yet they are sorely neglected with all the other senses. The epicure in Juvenal's day could distinguish between an oyster from the Lucrine Lake or from Britain. We could do as much were we to cultivate our natural powers as well. Cultivate these senses largely by a study of your own body. *Haud inexpertus loquor.* The hours I have spent in such study have been among the most remunerative, not only in the facts learned, but in the exact methods acquired, and the fine filing of the senses to a cultivated acuteness.

In all this I would not decry the use of the modern instruments of precision. Their introduction marks the beginning of modern science; when the balance, the yard stick, and the pendulum took the place of vague guessing at weight, length, and time. But, back of all our medical instruments, without which they are almost worthless, are our natural senses; and, if generously cultivated, they will largely replace them. Fifty instruments, though they can help, can never replace the five senses. In mountaineering, the Alpenstock is invaluable as an aid; but it can never take the place of a stout pair of legs.

This careful development of the senses must foster a spirit of exactness in all your work; in the use of instruments of precision as well as of the senses themselves. Science is always hostile to the word "about"—"about three inches long," "about one hundred and one degrees," "about ten days." When it is so easy to use the measure, the thermometer, the calendar, why say "about?" In the history of a case as derived from the patient, it may do very well; but in your own later notes it should never appear. One of the surprising and characteristic differences between most of the laity—even very intelligent men and women—and ourselves, is their inaccurate observation or non-observation of plain facts. This is due solely to the want of training of their natural senses, and is the best argument I can give you for the schooling of the senses.

I am well aware that during your collegiate course you will have only moderate opportunities to use Nature's gifts—in my day we had none at all—and that most I have said will rather apply to your post-collegiate course. But the accurate scientific habit or the shiftless unscientific habit will be begun and largely formed here, and it is generally true that what your habits are when you graduate, such they will be until Time shall administer his last anodyne and you pass into your long sleep.

Given the facts, accurately observed and carefully noted, what then? Then comes the highest art of the physician; the reasoning process by which is evolved the diagnosis, upon which depends his treatment. He must take one plus one and make them into two, a *tertium quid* wholly distinct from either of its constituent factors. And in medicine the two ones often lie far apart. They must be correlated not only in any individual case, but in cases years asunder, by a mental stereoscopic vision, the possession of the few, the envy of the many.

This logical faculty is partly inborn, it is true, and varies in natural strength as much as the natural acuity of vision; but it is also amenable in an immense degree to cultivation. The wider your knowlege the better your reasoning will be. You must at first laboriously toil over the process, as does the tyro in Euclid over each equation in every successive problem, over and over again. But when these steps have become as A, B, C to him, then he begins to leap, and finally, when a master geometer, his "therefore" clears a whole book at a bound. So with you, the halting method of your early days, if carefully purified from its faults and strengthened by constant and watchful repetition, will at length give way to quick perception; the correlated facts soon become as familiar to you as his old friends, X, Y, and Z are to the geometer, and with a mental "therefore," you, as quickly and as accurately, leap to your diagnosis, and thence to your treatment. Painstaking and habitual induction slowly give place to intuition. To the laity it often seems so easy and takes so little time it is hardly worth paying much for. They should learn that it is like the ease of the accomplished athlete, the swordsman, the equestrian. As in a plant, the long roots are hidden; only the brilliant flower is seen.

Of treatment, the last and most important point of

all—the "final cause" of there being any doctors at all—you will hear and see so much that I will only quote Broussais: "The real physician is the one who cures; the observation that does not teach the art of healing is not that of a physician; it is that of a 'naturalist.'" And I add my commentary: "The observation of the naturalist must precede, as it ought to lead up to, the art of the physician."

You will be much tempted to devote yourself to one or two favorite branches, to which you perhaps think you will devote yourself later as specialists, and to neglect others. No greater mistake could be made. Few men follow their early selection of a career. Circumstances compel a change. This collegiate part of your course stands in the same relation to your later professional life that a common school education does to your general education.

Every one must know the three R's whatever he may be, "farmer, lawyer, doctor, chief." So every doctor must know chemistry, though he become a surgeon; the eye, though he practice medicine; the microscope, though he become an obstetrician; obstetrics, though he turn out a pathologist. Each is a strand in the stout medical rope, and without it the rest would be weak and worthless. You must "know something about everything, and everything about something." Every department of medicine must pay tribute to the one you finally select. As Bordeu quotes Iphicrates, the Athenian general, when asked why he was so proud: "Are you a soldier, a captain, an engineer, a spy, a pioneer, a sapper, a miner?" "No," said Iphicrates, "I am none of these, but I command them all."

3. The Post collegiate period, or that of actual practice.

"Commencement" is not inaptly named, for it is the beginning of the work of life. I was not idle as a student, but I am sure that I have labored twice as hard since I have had my coveted sheepskin as I ever did to get it. "In nature," says Emerson, "nothing is ever given away. Everything is bought." For some things we pay dollars, for others, time; for others, hard labor. Time and hard labor are the sure and only currency of the realm of medicine. These alone bring success. And by "success" I do not mean wealth, or influence, or fame, the presidency of this medical society, or a professorship in that medical college. Success is a relative term; related to our sphere in life and our opportunities. There is a dignity in mediocrity, as well as of greatness. The humble country doctor—like the Gideon Gray of Scott's Romance—if he has kept abreast of the times by after study, and has made the most of himself and his opportunities, has achieved true success. Let me now enumerate some of the means needful to this end; especially needful in view of the demands of the new era.

A doctor who takes no medical journal is like the business man who takes no newspaper. Years after graduation he stands just where he did when dubbed an M.D., barring a certain amount of rule of-thumb experience he may have obtained. He is like a mariner who would stick to Fulton's antiquated steamboat instead of an Atlantic liner. The medical newspaper stands in the same relation to medical books, that the daily newspaper does to works on history; the one gives us the current events and thoughts and discoveries of the time, sometimes true, sometimes false; the other consists of the sedimentary deposits, gradually hardening into the rock of well ascertained facts. To keep up with the rapid progress of medical science you must, therefore, first of all take as many medical journals, and also buy as many books as you can afford. Make a note of every paper of importance in an index rerum, or better by a card catalogue, such as is used in all our libraries. Skimp your table and your wardrobe that your mind may be fed and clothed. This is your capital in trade.

Carry with you into practice the habits of accuracy, the healthy use of your senses that you will begin here. Accept all the helps modern science has given and the many others yet to be added to them. Study each case, especially your early ones, till you know them as you know the topography of your own at that time too unfrequented office. One case thoroughly studied will do more to enlarge your knowledge and teach you methods than a score observed in a careless, slovenly manner. Make notes of every case you have, full notes for the important ones, slight for the trivial ones. What would I not give had some one offered me and had I heeded just this one bit of advice! Patients soon come to the man who is interested in each case, studies it thoroughly, and, therefore, as a rule, cures it surely and quickly.

Now, too, will come the time when you can remedy any defects of early education. If you do not know German and French, you should begin to acquire at least a reading knowledge of both, within a week after you have your diploma, possibly even before you get an office. You have conquered a new realm when you have acquired a new language. No medical man at the present day can, by any possibility, afford to be ignorant of at least these two. If he is, he simply must go to the rear. With these I must enter a plea for the sturdy sonorous Latin, and if possible some Greek. Never forget that ours is happily one of the "Learned Professions," and if we would be worthy of the name, some little classical, as well as scientific, learning should shed a halo around it. Not only is it needful for your very first prescription, and for the intelligent appreciation of most modern scientific terms, but it leads to the highest and noblest literature. If you have once tasted of the honey of Hymettus you will hardly be satisfied with the miserable crumbs found in many of the current and much be-thumbed books of the day. A literature that has dominated the world for over twenty centuries has a right to claim some of your time.

Do not shelter yourselves behind the incessant work and endless drives of a "country doctor." I fear that many of our country doctors waste enough time in gossip and profitless discussions of the crops and politics, and what not besides, to make them excellent Latin scholars at least. Even the long drives alone, if rightly used, would suffice to add one or two languages to their literary furnishing. One of the most remarkable medical pictures of the time is that given by Dr. John Brown, of Dr. Adams, of Banchory, a "country doctor" in a secluded Scotch village, with constant hard work on horseback, amid bleak hills and valleys for twenty miles around. Without ever neglecting his work he became one of the most accomplished linguists of his day, and at breakfast was fond of amusing himself by translating an ode of Horace into Greek verse.

A happy distinction has been made between the "Literature of Knowledge" and the "Literature of Power." Our science brings us so constantly into contact with the first that we are apt to neglect the second. Much of the literature of power you will find in Homer and Demosthenes, in Horace and Cicero, in Moliere and Goethe; but for a wide acquaintance with it you must naturally look to our mother tongue—and, happily, you do not look in

vain. Chaucer and Shakespeare, Milton and Macaulay, Tennyson and Thackeray, Whittier and Longfellow, Webster and Irving, and the genial Oliver Wendell Holmes—one whom our own guild ever delights to honor—these will conduct you into the higher realms of thought, where you may soar undisturbed by care. "Some books," says Bacon, "are to be tasted, others to be swallowed, some few to be chewed and digested." Read the books that are to be eaten and assimilated.

I urge this literary culture partly because it will afford endless delight, and broaden and inform the mind. In later life, when you have lost some of the fine enthusiasm of youth; when the years come that bring the philosophic mind, familiarity with such a literature will be a never-failing resource, for it never loses its charm. But I especially urge it because the new era in science demands that you be ready to report your cases, relate your discoveries, and discuss them before an intelligent public. To do this so that you will command a hearing, a good English style is indispensable. Few scientific men speak or write effectively. They are apt to be illogical in their methods, wanting in force in their arguments, discursive and inelegant in their style. If you will make the literature of power your companion, and then will write and then prune mercilessly, you will soon acquire such a command of English as will serve you many a good turn. The secret of Huxley's and of Tyndall's success lies as much in their forceful and elegant English as in their scientific acquisitions.

Beside all these scientific and literary demands, I cannot pass by those personal qualities that the age requires of every gentleman. Cultivate, therefore, neatness of apparel, a courtesy that is so apparent that it is extended to the humblest patient in as large measure as to the rich and influential. Appreciate that yours is not a trade in which to make the most money in the least time, but a generous profession, by which, it is true, you make a living, but also do far more. You give what money cannot pay for, and for which you will often never even ask for any sordid *quid pro quo*. Devotion to duty to the neglect of self, sympathy and succor in the hours of sorrow, cheerfulness that vanquishes despair, and skill that baffles even death itself, these are not to be paid for by money, but by speaking eyes, grateful hearts, and well-cemented, life-long friendship and devotion.

Above all, cultivate that good old virtue, "common sense." It lies back of all your science. It is the bed rock on which all success is based.

Of your moral and religious duties I may add only a word. Medicine has to do with much more than the mere healing of human infirmities and disease. Its investigations carry you far beyond the animal kingdom, away down to the lowest vegetable organisms, which bacteriology has shown to be such important factors in disease; its practice has to do with the health and highest happiness of vast communities, as well as the welfare of each individual, with all his various ties and relations, in one complex social life; and its speculations carry you far above and beyond the hour of death. We assist at the beginning of the earthly life in its frail cradle; we see its very close when we watch the last respiration and feel the last pulse beat. That this is not the "be-all and the end-all" of a human soul, both Holy Writ and our own inner convictions imperiously assert. If we could but discern it, we have really assisted at the beginning of a second and the greater life—the Eternal Life. Mindful, then, of our high calling, we should be thoughtful and religious men, ever asking for the Divine help in our daily round of duties.

When I began writing I had intended to speak at length also of the demand of the new era in medicine upon our medical colleges. Time, however, will only allow of a brief, but most important allusion to it. To this demand the colleges are slowly responding. But the change should be more general, more rapid, and more radical.

It is one of the most healthful signs of the times that it is in the larger and more advanced schools, the very ones that are best equipped as to men, money, buildings, and laboratories, that there exists the greatest unrest and dissatisfaction with present achievements, and the chief reaching forward to better and larger things, and among them stands the Jefferson Medical College. While conservative, she is progressive; "*Nulla vestigia retrorsum*" is her motto. That she is alive to the need of progress and has met it in the past, the contrast I have described between my own student life and yours gives ample proof. That the new era in medicine demands still more she recognizes, and, as you will have seen by the announcement, she again meets the demand. To your joy no less than to mine, for the student-mind is ever alert to notice signs of progress, this year we inaugurate a full and required three years' graded course. Time was when the comparatively narrow field could be reaped in two combined hearty attacks. Even then it was hard work; but now it has become simply impossible. The profession and this college alike recognize it, and accordingly we provide for it. If, with increasing branches of science, and increased demand for a deeper as well as a wider knowledge, a reasonable experience shall, as I believe it will, conclusively show that more is needed, I am persuaded that the Jefferson College will recognize that need, and provide for it in due time.

In connection with this progressive step, I am glad to be able to announce to you that, during my late visit abroad, I had an interview with Mr. Hallett, the courteous and intelligent Secretary of the Conjoint Board of Examination of the Royal College of Physicians of London and the Royal College of Surgeons of England, and that these two colleges have accorded to the diploma of the Jefferson Medical College precisely the same rights and privileges that are accorded to the diploma of the universities of Paris, Berlin, Bologna, and all the best foreign schools.

As an earnest of the progressive disposition of this college, I have also the honor of making to you another announcement. Within a short time, the wise forethought of the Board of Trustees has been well shown in the purchase of a lot eighty-two feet in front on Walnut street, south of the hospital, upon which a new and commodious college building will be erected, an ornament to the city, and a more active center of scientific life. Nor will the old and battered college building be given up to baser uses. Hallowed by the memories of McClellan, Dickson, Mütter, Bache, Pancoast, Dunglison, Gross, and scores and hundreds, yea, even thousands, of earnest teachers and pupils, and remodeled, it will take a new lease of useful life by gathering under its hospitable roof the many well equipped laboratories of the college, all of them the product of the last twenty-five years. This is happy news, especially to the workers in the ill-equipped, insufficient quarters of the past, which yet have been the scenes of persistent, patient, and most useful scientific work.

But to erect a new college building and alter another, and equip the laboratories, will take money, and a deal of money. For this we must appeal largely to the generous sympathies of a community long noted

for its intelligent benevolence. Yet it is an odd fact, to which I call especial attention, that, while to academies, colleges, seminaries, and other institutions of learning, millions have been given, and to hospitals scores of millions, yet, to fit the men who are to serve these very hospitals, to educate the doctors who are to have the health and lives of the whole community in their care, nothing has ever been given until of late. At last we are awakening to the fact that good doctors are as important as good teachers and preachers, and that physical health is no less important than mental development. To erect suitable buildings for an important medical school, and to equip and endow its laboratories and museum, is as much a work of philanthropy, and brings back ultimately to the community as large a return as similar gifts to academic institutions or to hospitals. We have already hospitals and dispensaries, and asylums and homes in excess of the needs of the community. What is needed now is the strengthening and development of the *medical schools* which educate the men who make the hospitals useful; the endowment of laboratories in which original research will continue for all time; researches which will repay for their outlay a thousandfold; and the establishment of scholarships and fellowships, to enable young men whose devotion to a scientific career is hindered and often blighted for want of reasonable pecuniary help. For these innovations and encouragements we now ask money, and the indications are that the community is alive to the need for them. The recent endownment of the Chair of Surgery in the University of Pennsylvania, the erection of the new buildings at Harvard and New York, the establishment of the Carnegie, the Loomis, and the Hoagland laboratories, and especially the magnificent gifts of the Vanderbilt family and of Johns Hopkins at Baltimore—all these are encouraging signs.

The Jefferson now boldly proclaims its work, and asks for similar help. The new era in medicine compels us to enlarge our facilities, and this wider and better instruction will benefit the public at large. To them we appeal confidently, knowing that they will not disregard an appeal founded alike in justice, mercy, and charity.

And the reasons urging on this college to these large and wise advances apply equally to the other medical schools, and to the profession at large. The demands of the new era in medicine will only be complied with when the medical colleges give all the necessary facilities in equipment and in time to study thoroughly every branch of medicine, and the student comes to the college with a suitable preliminary education, avails himself during his college course of the ample means provided there, and after graduation grows into the cultured and experienced doctor by the means and methods I have pointed out.

ADDRESS DELIVERED AT THE OPENING OF THE TENTH ANNUAL WINTER COURSE OF THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

By SAMUEL WOLFE, M.D.,
Professor of Physiology.

GENTLEMEN: This hour may have in it something of expectation. In the formal opening of the main term of an institution of learning, something, possibly much, may depend on the manner. The first step, the primary movement, the initial impression, has often a vast determining influence on subsequent events. You may know that with these thoughts I approach my task with great diffidence, yet hoping for your gracious consideration while I attempt its faithful performance. Is our institution, in the sense of a continuous influence, in the sense of a steady force, ever closed? Is the term "opening" strictly in accord with the tenor and spirit of this occasion? The low and plaintive ripple of the river's stream over a pebbly bottom may not be as majestic as the roaring, dashing current, with its seething volume, but with the same unerring certainty the former, like the latter, finds the sea. While the latter has been quickly gathered from the surface, and is muddy, turbid, unclean, the former represents the filtered products of the hidden springs, and is cool, clear, and pure. The torrent, gathered from the surface, may, by its overflow, sweep from the banks fragile, insecure, and ill founded structures, cleanse the bed of filth and putridity, while it leaves the great trees that have anchored their tap-roots deep in the lower soil freshened and revived. But it is on the placid stream that the boat floats with the more safety, and the regular, smooth current it is that drives the wheel of the mill with the most certain force. So may the thoughts that have silently crystallized while these doors have been closed now flow forth and become greater factors in your education. There will be the brilliant products of the inspiration of the hour, or the lively energies bred purely by the associations of the season.

No, gentlemen, the rhythm that applies to the openings and closings in our college calendar must not, cannot, does not apply to our mental structure. And who are thus concerned? I mean the gentlemen who, for the first time, to-day are with us as matriculates; they who have, during one or two previous terms here, so faithfully pursued their studies; and they who now come, with trembling hope, to the closing year of their course; to the session that will endow them with privileges for which they have so long labored earnestly. I mean this honorable and learned staff of teachers, and this body of men to whom are entrusted the material affairs of this institution. I mean the alumni, whether here or elsewhere to-day; and as much, yea, more than all, I mean those who, by their friendly presence, their kindly support, and their generous encouragement, constitute our patrons and friends. Can it be that the thoughts, the feelings, the labor of all or any of these have been totally disconnected from our institution in the interval between Commencement and Opening Day? And is there not, in this continuance of activity, the very essence of our school? Is it not to this concert and persistence of aim and endeavor that we must look for perpetuation? Though violence and disaster, or time, may crumble and dissipate the structure in which we assemble, so long as this spirit is left the Medico-Chirurgical College will exist. So long the novitiates, the undergraduates, the alumni, the faculty, the trustees, and the patrons will be moved and directed by kindred motives, and the harmony of forces will conduce to such ceaseless progress that, whether in session or not, the institution will be open. But there is yet entire fitness in the custom of approaching the routine duties of the main session in this formal way, and were only my powers to correspond to my opportunity, I would hope to be eminently useful to you on this occasion. Graceful language, elegant diction, and the most delicate wit could not, however, free from arrogance and injustice any appeal to you, my honored colleagues, to add aught of effort or labor to what the past has already promised to the future. It were treason to your trust and kindness for me to impugn

your work already done, or to question your intentions in that which is before you. Neither could I bestow proper tribute to your worth, nor pronounce due compliment to your all pervading zeal. Were such your need or desire, the result of your work would furnish it with far more force than any weak and prosy sentiments I might express. Of our friends, who have honored us with their presence, we have no reason to complain, and a spirit of gratitude and appreciation becomes us far better than any attempt at counsel or advice. There remains, then, but the contingent of the student, and with the mountains of art rising before him, that must be scaled; the caves of science yawning, that must be explored, and the oceans of philosophy rolling, that must be fathomed, it were but merciful to spare him, lest a too sudden application should appal him. But he comes with the ardor and eagerness of youth; with the health and vigor of early manhood, and, moreover, with the expectation of professional discipline and management, as well as with curiosity and anxiety for the solution of the mysteries of science, and the, to him, probably greater enigma of the final trial. To him, then, I may venture a few words of advice as to the course most profitable towards the desired end.

And what is this desired end? Is it simply to gain the certificate which gives you the legal right to register as a practitioner of medicine? If such is the case, you have reason, indeed, to bemoan the loss of the broad privileges of earlier times. Within easy memory not even a diploma was required, and even less than a score of years ago, when such an instrument had become more essential, it was very cheap. Without study or preparation, and for but the merest trifle in the way of money, you might then in this very city have secured your own, and if actuated by prudent foresight, you had seen fit to provide for your children and grandchildren, even though still only prospective, you would hardly have found difficulty. What glorious liberties these which your fathers enjoyed, and how must your feelings fire at the thought of their ruthless sacrifice. To you, if you have no other motive, there can be no gratification in the fact that you are matriculates of a school of medicine, which has no loftier source of pride, than that standard which permits it to appear honorably amongst its most honorable and advanced sister institutions, other than which, thanks to the noble efforts of the leaders in our profession, we now have none among the regular colleges, in this, the medical centre of our great progressive nation.

But I am convinced that no such base views of the requisites for entrance into the profession play any part with you. You are laboring for a position, where no college faculty, no board of examiners, no licensing power shall be the ultimate arbitrator. You want to plead your cause, and get your commission, at the court of your own conscience, where a record of a sufficient season, well spent in strict discipline, and the attainment of thorough culture shall avail. You mean to take your place amongst the honest faithful devotees to professional duty; with the diligent students of scientific medicine. You would scorn to rank with the charlatan and pretender; with those who sneer and scoff at the advancements of the day.

You are not to be misled by the glittering show of success, which all too often seems to emblazon the careers of many such desecrators of the sacred precincts of medicine. You are ambitious to gain rational confidence, not ignorant credulity. You have your models in the Hippocrates, the Harvey, the Hunter, the Rush, the Mott, the Gross, and the Pancoast of the past, and in the Davis, the Leidy, the Agnew of the present. You are awaiting the time when your energies may grapple with the great medical problem of the day, with a force and vigor begotten by close acquaintance with and thorough comprehension of the principles and facts on which their solution rests. You are approaching a period when you expect to justify your patient's trust by the exercise of thoroughly drilled faculties. You are pushing forward into a profession which has in its keeping the key to the solution of some of the most important social and economic questions of the hour; which has rendered, and is destined still farther to contribute to municipalities, commonwealths, and nations, services as noble as ever sprung from mighty martial hosts. You will stand to the individual, in the relation of daily counselor on the most weighty, as well as the most delicate concerns of his existence. You will be to him, under God, the very keeper and dispenser of that existence, and when the hour for him shall come, when he will see your lease of power ended, in his dying gaze, and in his expiring moan, will still be an appeal to you, for your steadying skill, and for your comforting sympathy. Such duties you do not advance on with trifling and thoughtlessness. No! Your are in earnest, and, therefore, I take it, willing to receive suggestions intended to facilitate your progress, and to direct your labor into the most useful channels.

I, of course, presume to be speaking to students in every grade of the curriculum. For such as are availing themselves of the fourth year of instruction, whether as under-graduates or post-graduates, a rich supply of studies is laid down in the roster. The regular methodical pursuit of the full line must not be far deviated from by those who want to make the best of it. It is supposed to rest on the studies of the previous years thoroughly mastered, especially such as are generally regarded as simply fundamental, or not practical, and is, therefore, mainly clinical. It aims to bring specialized medicine before the student in such a way that he may get such a grasp on the whole line as will largely aid his usefulness, and probably greatly conduce to his success in general practice, or that he may make the most enlightened choice of the particular field to which he would confine his work.

Though it may be fairly presumed that the most capable and industrious student may here use up all his available time, yet there arises, also, such a golden opportunity for extraneous studies, that you may need to question whether you should not embrace it. Your residence in a large city, your going in and out at a medical college, your proximity to large museums, hospitals, and scientific institutes, may end with the present course. If you leave these behind, without having well rounded out your knowledge of chemistry, anatomy, biology and pathology, which you can nowhere study as in the laboratory, the dissecting room, and the museum, you will carry a regret with you, that will arise and confront you at every turn of your professional career. If you must sacrifice anything, let it rather be the sight of an occasional capital operation, the demonstration of a brilliant diagnosis, or the building up of a highly scientific formula. Understand me, I do not wish to undervalue these exceedingly important elements in a medical education. I mean rather to note, that a lapse in this direction may be more easily mended from books and practice, than such as pertain to the fundamental sciences. And that nothing will so seriously hinder

and cripple you in your work as practitioners, as the "rustiness" which you so often are referred to, by the active men in the profession, to explain the hesitancy when a point in anatomy, physiology or chemistry arises. I am seriously inclined to explain many of these cases of "rustiness" as congenital, rather than acquired. Let me then, gentlemen, call on you to carefully examine into your own condition at this time, and if you discover such defect, let me advise early operation for its removal. As to the studies laid down for you to occupy this year, I can disparage none, but I think experience teaches that the average practitioner is most freqently deficient in pediatric, dermatology, forensic medicine, mental and nervous diseases and otology. It should hardly be necessary to emphasize the importance of particular attention to the peculiar features of diseases of children, and the special line of management that applies to them, since we are all aware of the large share of the physician's work which they constitute. Never will you feel your helplessness more keenly than when you find yourselves unable to construe the manifestations of disease in these innocent sufferers. Yet had you properly learned to interpret it, they would speak to you in a language that would convey far more truth than do the dissembling statements of the crafty master of his tongue. The impulse which the recent advances in the physiology of the nervous system have given to the study of nervous diseases, has resulted in making that department so attractive that the student will need but little urging to employ all the time he can command in this direction. To stimulate us to the attainment of proficiency in forensic medicine, we need only to regard the tenderness and affection of our neighbors, the lawyers, for us. The kindness and cordiality with which they treat us as witnesses, serves to brighten many a dark and painful hour with the hope that we may soon be called into court. How eagerly then, if only for the mere purpose of reciprocation, and out of a pure respect for their unflinching devotion to truth and veracity, should we cultivate a learning commensurate with their demands upon us, in their immutable pursuit of right and justice. To you who are entering your third year, many of these suggestions seem to me equally applicable, and probably the most urgent advice to press home, is that you should, if possible, avail yourself of our fourth year, and therefore make it in a twelve-month entirely and directly applicable. But that portion which refers to a full and comprehensive study of the primary branches, should not have its application postponed. The need of it can only exist through an inversion of the order which our graded course is intended to establish, and such mistakes as you have made in this direction cannot be too early corrected.

Develop the art that belongs to your calling rationally—out of your scientific knowledge of the materials and principles, with which you must work, and you will enter the profession not only more sound and more cultured, but also more expert and skilful. With the majority of you, I dare say, your school privileges will close with this session. Look well, therefore, to your start, and make the best of your perquisites while they are yours. The best methods and the utmost diligence will still leave enough undone, to call up regret. Beware how you slight, and take no risks that rest on sloth. You, gentlemen of the second year, will weigh in your right hand the theory and in your left the practice of medicine. You will view with delight the nice balance, the strong affinity, the perfect harmony between them. And I know of nothing more useful to recommend to you, than free indulgence in this fascinating pastime. See as you go along the essentiality of one to the other, and as the resources of art reveal themselves, be careful that there exist no breaches in the scientific bulwark behind which they are entrenched. My counsel to your seniors will then but faintly apply to you, when you rise to their grade. You will then have developed a taste for close investigation, a habit of tracing effects to causes, phenomena to determining principles, manifestations to underlying conditions, which will continue to serve you well, not only while you remain here, but after you engage in practice. You will then need no other stimulus than your own inclination to drive you to research and discovery, nor other mandate than that which will arise out of your own mental organization, to herald your conquest and glory.

And you, gentlemen, who to-day are on the threshold of your medical course, will already have gathered what I would have you do. Your eyes need not be closed, nor your ears stopped against the practical points that will continually present themselves. Let them stream in with perfect freedom. Lectures on surgery, practice and obstetrics, and clinical lectures are by no means objectionable; but you must not regard them as the main, or the essential features of your present year. These lie in your anatomy, chemistry, and physiology, and to these you must stand closely and steadfastly. They may grow tedious, and weariness of their methodical and didactic study may drive you to the other more tempting sections. And to recreations of such an exalted type there can be no opposition. But, remember, they are only diversions. Your serious attention, your faithful study, your hard work, your sturdy blows, belong here—here on the groundwork of the superstructure you propose to erect.

There must be no quicksand beneath the foundation wall; every stone must be properly laid and tied in its place; layer must rise on layer, and timbers must be framed and placed. But it were pure folly to attempt to fit in a beautiful piece of stained glass, or a delicately-carved panel, where yet no wall or framework had arisen to hold a casement. It is true, the wise and prudent builder, while the walls are rising, is buying and storing for future use the materials which are to be used in the finish and decoration of his house; but he is careful not to put them where they may impede the earlier processes, or where the integrity or fineness of their structure would be prejudiced while this rough but essential and important work is going on. So you, too, may, and should, glean, and handle, and sort, and polish what you must closely apply and fix at a later time, but always in the intervals of your routine duties, and in such a way that it will neither obtrude itself on your regular work, nor suffer injury or disintegration from the incongruity of its surroundings. You have, as yet, no breaches of neglect and oversight to repair. The less such you create as you proceed, the more reason will you have to rejoice at a later stage. Take the studies laid down in the roster, put there by such as have viewed your needs from the light of long and extensive experience; be sure that you acquire each and all thoroughly; and if, at the end of the year, you may perchance feel that you have not advanced one step towards becoming a practical physician, two years later you may find your opinion overthrown, and will not only be the peer, but the superior of your bright classmate, who has so often awed you by his recitals of his brilliant diagnoses, and begotten your

envy by enumerating his great list of patients. Be neither in too great a hurry to acquire or to apply practice; for rest assured the day will come when you would rather sit on the student's bench than in the professor's chair.

I believe I might, with perfect confidence, call on each individual amongst my colleagues in the Faculty to ratify this, my own personal feeling; and I furthermore believe that every one of them, like myself, would, if there were no secondary considerations, prefer first to sit with the students of anatomy, physiology, and chemistry.

And now, gentlemen, having more or less directly addressed each class, and attempted some general directions that might apply to your mental discipline, I might consider my task finished but for the feeling that, with all these most carefully followed, resulting in a vast amount of theoretical and practical knowledge, you might still be most unworthy of entrance into the profession. For admission here, you "are required to present to the Faculty satisfactory evidence of a good moral character." Still more forcible demands in this direction will be made on you when you present yourself for the confidence of your patients. It is in the very nature of the trust to be imposed upon you that it should not be given to the profligate or debauched. To do your duty properly, you must share the most sacred secrets of patients and families. You will be obliged to decide questions of the most delicate and perplexing nature. You will bear responsibilities demanding unremitting care, long-continued toil, and intense application. Your practice will demand the display of undaunted courage and willing sacrifice. You will find failure in the most scientific prescription and in the most dextrous operation; but never in the exercise of fine force of character. As teachers of medicine, we are not supposed to look specially after you in this way. Your moral discipline will rest on yourselves. Character, at the age which most of you have attained, has taken decided shape, but is still quite flexible. The importance of care in its moulding is therefore at this season particularly incumbent, and the strength of will generally sufficient, and the power of discrimination adequate. You may be reasonably turned over to your own mastery, and, if you do not exercise it, will have but little room to shift the responsibility.

Take high moral ground then; plant yourself firmly on it. Early manhood is a season in which the full responsibilities of life are opening. Our emotions are powerfully dominating; pleasure has a peculiar fascination; desire prompts us to investigate everything; the moral faculties are taxed to their utmost to regulate the conflict between the diversified influences. The battle is inevitable, and must be made when the enemy attacks. The victory is not easy, but can be gained by hard fighting. Stand nobly to your guns, and flinch not till you see the hostile camp routed.

"Let us with caution indulge the supposition that morality can be maintained without religion," was the utterance of no less a man than Washington. This is no sectarian school, and your religious faith will in no manner be submitted to question. You need not, however, be too ready to accept what seems to have become in a large measure a part of public opinion: that science and religion are antagonistic; that profound scientific attainments are procured only along with agnosticism and infidelity. There are still great leaders in the scientific world that have conserved a strong degree of religious faith. I would advise you at least to hold on for the time to what you have. There need be but little doubt that there are here to day men who, in the fullness of time, will pale the lustre of the fame of Darwin, Huxley, Tyndall, and Herbert Spencer; but, even to these, their religious belief need not be for the present a serious hindrance. To say the least, avowed disregard for established religion will come with better grace when their mastery of science has asserted itself; and even then can give them no precedence over such as do not attack it, or even boldly own their continued allegiance. Your Sundays are not occupied here. In a great city like this, many men of powerful intellect and high character freely expound the ground of their faith; to such you may give an hour a week, with no detriment to your educational progress, nor to your social standing. Most, if not all, of you have been objects of pious solicitude on the part of those associated with your early training, and even now there rest on some of you tears of mothers, hardly yet dried, that have welled up out of anxiety and fear for you in this direction. Be careful not rudely to shock such tender sentiment; for life has in it but little so rich and grateful.

But I have said enough; and if I may hope that I have rendered even the feeblest service in guiding your efforts at this important stage in your lives, I am content. I would only add an expression of my interest in you, of my faith in your sincerity, and your disposition to instruction, in extenuation of what might otherwise have seemed presumptive, and a pledge to such future help as your solicitation may call forth, or as may lie in my power to furnish—a pledge in which I faithfully believe all of these, my illustrious colleagues, ready to join.

The Polyclinic.

MEDICO-CHIRURGICAL COLLEGE.

DISEASES OF CHILDREN.

FOR ephemeral fevers, disturbing the child for one or two days, then disappearing, whether associated with teething or gastric trouble, the following combination is of great value:

℞.—Acetanilid . . . . . gr. xviij.
Hydrarg. chlor. mitis. . . . . gr. j.
Sodii bicarb. . . . . gr. xij.
Sacch. lact. . . . . gr. xv.
M.—Ft. chart. No. xii.
Sig. One every two hours until three are taken.

In conjunction with this, or as a preliminary treatment, if the bowels are much constipated, the following aperient should be given:

℞.—Sodii bicarb. . . . . gr. xvj.
Syr. rhei,
Aq. cinnamomi . . . . . āā f℥j.
M.—Sig. ℥j until the bowels are freely moved.
—*Hollopeter.*

℞.—Acidi nitro-muriat. . . . . gtt. xxiv.
Tr. cinch. comp. . . . . f℥j.
Syr. simp. . . . . ℥ij.
M.—Sig. ℥j ter in die.

The above is an excellent formula to use where clearing the skin and tongue and improving the appetite are required.—*Hollopeter.*

Phenacetine acts more as an hypnotic, and is slower in its effects than acetanilide.

Acetanilide always produces profuse diaphoresis in children.

Phenacetine will answer for opium, which children bear so poorly.—*Hollopeter.*

The following is an excellent fever mixture for a child one year old:

℞.—Antipyrine . . . . . gr. viij.
Aq. cinnamomi,
Syr. aurantii cort. . . . . āā fʒj.
M.—Sig. ʒj every two hours until fever subsides.

The antipyrine being soluble, goes into the circulation more rapidly than acetanilide, and so breaks the fever sooner.—*Hollopeter.*

For children whose digestion is greatly impaired, and subject to colic with a tendency to increase in severity, the following will be found valuable:

℞.—Chloroformi . . . . . ♏viij.
Syr. rhei. . . . . fʒj.
M.—Sig. Ten to fifteen drops up to ʒss in a little water.
—*Hollopeter.*

To break up a cold in children, a combination of phenacetine and sugar of milk will be found useful.
—*Hollopeter.*

For persistent vomiting in a child one year old, give the following:

℞.—Hydrarg. chlor. mit. . . . . gr. ss.
Bismuth subnit. . . . . ʒss.
Sacch. lact. . . . . gr. xv.
M.—Ft. chart. No. xii.
Sig. One powder every two hours.

If this fails, give:

℞.—Creasoti (English beechwood). . . gtt. j.
Sacch. lact. . . . . gr. x.
M.—Ft. chart. No. xii.
—*Hollopeter.*

For infantile colic, with alternate cold and hot spells:

℞.—Sodii bromidi,
Sodii bicarb.,
Chloral hydrat. . . . . āā ʒss.
Aq menth. pip. . . . . ʒj.
M.—Sig. Ten drops up to ʒj, every fifteen minutes or half hour until desired effect is obtained.
—*Hollopeter.*

A good combination of a tonic and an aperient is the following, serviceable in cases where there is evidence of a disordered nervous system, attended with atonicity of the intestines:

℞.—Acidi muriatici . . . . . ʒiij.
Strychninæ sulph. . . . . gr. ⅔.
Tr. belladonnæ . . . . . fʒj.
Syr. rhei . . . . . q. s. ad. fʒiij.
M.—Sig. ʒj thrice daily.

The tinct. belladonnæ will act as a "peristaltic persuader," and is well borne by children.
—*Hollopeter.*

FOR SCABIES.

℞.—Lac. sulphuris . . . . . ʒj.
Beta-naphtholi . . . . . gr. x.-ʒj.
Bals. Peru . . . . . ʒj.
Adipis benz. . . . . ʒj.
M.—S. Apply after a hot bath.
—*Gans.*

FOR ECZEMA ENCRUSTED.

℞.—Ol. olivæ,
Ungt. hydrarg. oleat. . . . . āā ʒj.
Ol. cadini . . . . . ʒj.—M.
—*Gans.*

Never give digitalis in heart disease when compensation is perfect, but endeavor to improve nutrition by attention to the *regime* of the case. When you hear a mitral murmur don't give digitalis until subjective symptoms are complained of—*Anders.*

FOR INFANTILE ECZEMA.

℞.—Hydrarg. chlor. mitis. . . . . gr. ij-x.
Acidi carbolici . . . . . gr. ij.
Pulv. marantæ. . . . . ʒj.
Ungt. aquæ rosæ,
Ungt. zinci oxid. benz. . . . . āā ʒss.—M.
—*Gans.*

CHRONIC CERVICAL ENDOMETRITIS.

In the treatment of chronic cervical endometritis, the application of caustic agents should not, as a rule, be employed, for the reason that they irritate and induce congestion of the parts, and, if persisted in, cause the formation of cicatricial tissue, which may in turn give rise to dysmenorrhœa, by diminishing the caliber of the cervical canal, or induce neuralgia by impinging upon nerve filaments. Especially is this the case in the non-parous subject. It is best to dilate the cervical canal with bladed dilators, unless marked sensitiveness of the parts contra-indicates such a procedure. Dilatation allows the free escape of the discharge, and renders applications more effective.

A constant irrigation of hot, medicated water, will add to the ease, effectiveness and safety of the operation.—*Godfrey.*

Remember that where you have consolidation and a consequent dullness upon percussion the pitch of the note is increased. This increase in pitch is often mistaken for increase in resonance.—*Anders.*

In an abscess of the mammary gland, in addition to the breast-pump, the following salve spread on a flannel and applied to the breast, will invariably hasten the drying up of the affected mamma:

℞.—Ext. belladonnæ,
Pulv. camphoræ, ... āā ʒij.
Ung. tabaci. . . . . ʒj.
Cerati simplicis . . . . . q. s.
—*Stewart.*

In introducing a bougie into the urethra disabuse your mind of the idea that the benefit to be gained is from distending the caliber of the urethra. That is not so. In introducing a bougie into the urethra we produce compression, in virtue of which the inflammatory products are resorbed. A bougie in the urethra acts as a compress-bandage does elsewhere.
—*Laplace.*

In the treatment of external aneurisms, Prof. Laplace takes a large cork, hollows it out, so as to fit perfectly upon the tumor. It is held in place by a figure 8 bandage placed upon the limb held in a semi-flexed position. The patient can regulate the pressure to suit himself, complete extension producing the greatest pressure upon the tumor. By this means the pressure is distributed equally around the tumor, the flow of blood is thereby not stopped, but the friction of the resisting walls gives rise to coagulation of the blood, which deposits in fibrinous layers on the walls of the aneurism, thus strengthening it and relieving the patient from the danger of a rupture. This method was suggested to him by observing how nature cured an aneurism of the arch of the aorta.

Tonics administered to persons leading sedentary lives, are worse than useless, unless you can combine with them a proper amount of exercise. Tonics stimulate tissues to greater activity, but of what avail is that if from a lack of oxygen the tissues are prevented from assimilating the food products ingested?
—*Waugh.*

THE STUDY OF LATIN.

THE fight against Latin is still being waged, and doubtless will be waged for centuries to come. It is continually cropping up when some strong, well-poised man, endowed with that directness of thought that comes of limited vision, endeavors to sweep away everything which does not bear straight upon the things that occupy him. Locke was such a man; limited in vision, in that he shut out all that came not directly and clearly into his focus; though his limits would have circumscribed the infinity of many men. Schiller possessed the same faculty; Tait is the best living example of it, though every specialist, pure and simple, shows it in some degree. So Locke thought that for the years spent in the acquisition of Latin by the old process of digging out, root by root, could be profitably substituted the use of translations, by which the student, with the same amount of study, could, in a short time, attain a thorough knowledge of the language. This may be so; but we cannot look upon the "interlinear" with the affectionate feeling with which we handle the old Delphinis, with their antique typography, and notes in Latin as difficult to construe as the text of the author. Far from regretting the time spent in unraveling the knotty clauses of Ovid and Sallust, Juvenal, Terence, Lucretius and Tacitus, we *know* the labor was most useful discipline; and believe that no modern scholar can equal those who took it.

To learn a thing quickly and easily is not the *summum bonum* in education, nor is the acquisition of knowledge its sole aim. The training of the mind, strengthening and disciplining its faculties, the development of those powers that will best aid its possessor in the coming struggle for existence, are the true objects of schooling, to which the acquisition of facts is but an incidental factor. The mastery of that tough old antagonist, "*Tigna bina sesquipedalia*," leaves a boy stronger and better for the struggle, although his rendering may not be as smooth as that of the youth who reads off glibly from his "pony." What possible influence can the latter method have in the development of manliness?

In the German gymnasia, students are thoroughly drilled in the classics, while these are omitted in the Real schools. Experience has shown that in the subsequent medical course the students from the latter could not compete with those from the gymnasia.

The demands of the day are not so much for a change in the character of the studies to be pursued, as in a lengthening of the course. In ancient times, very little was required of the youth who was to assume the dignity and bear the burdens of manhood. Simply killing another man was the only requirement among many nations. The age of fourteen marked the passage from childhood in some instances. As the world grows more learned, more crowded, more crafty, the age for the assumption of the virile toga is placed farther from infancy; and although the legal period is the twenty first year, many youths are not really independent of their parents and fairly established on a self-supporting basis for years later.

This is, assuredly, not for the lack of sufficient acquisition of facts. Were it so, there would be some truth in the suggestion that "we waste the best years of a boy's life in teaching him the dead languages, rather than those of modern Europe, which he will have occasion for in after life, or than some really useful subjects, such as modern history and the physical sciences." It is not the want of general information that keeps our boys at their fathers' side until they are twenty-five, but a lack of the wit to use their knowledge. In other words, they must develop their brain power until they can successfully cope with the facts that may be presented for their mental digestion, before they can leave the parental roof with safety.

As this truth becomes appreciated, the post-graduate courses of literary and of medical colleges will be better appreciated. By these there is a practical lengthening of the college courses, and in an admirable form, for they are limited to those who can profit by them, not being in any way obligatory.

MEDICAL ETHICS.

THE physician who refuses to attend a patient who cannot pay his fees is looked upon as mercenary; as not living up to the highest standard of the medical profession. But when we hear that a prominent Philadelphia physician, whose name is familiar to every resident in that city, after the close of a long and useful professional career, left an estate valued at seven dollars, we wonder whether the high standard is worth keeping up. The belief in another world, where his treasures are laid up, becomes a necessity to save the good doctor from the imputation of folly.

It is the wisest policy to speak nothing but good of our neighbors; first, last, and always; no matter how much their conduct justifies us in pursuing the contrary course. If a brother physician behaves ever so shabbily towards us, it is best to let him hear of nothing but kindly words from our lips. There may be in existence a man who can still go about vilifying one who speaks well of him, although we have never met such an one; but he is not at all

likely to find any one to believe him. On the contrary, if we detect our enemy in some glaring professional mistake, and lay bare his culpability to the light of day, sure as fate the time will come when he will have a chance to strike back at us. There was once a young fellow who, in his eagerness to get into practice, behaved very badly towards the writer. The young man had an aged mother to support, and was hard pressed; but we did not know it then. In fact his behavior was so very bad that we determined to pay him back in kind. The chance came. He had evidently been reading Sayre on phimosis, and saw all things through phimosis' glasses. He was called to treat a little boy in a family we attended regularly, found that he had phimosis, and rushed off for his circumcision tools. In vain the mother begged the doctor to look at the child's sore throat and ascertain the cause of the fetid breath. He had seen the phimosis, knew it was there, and was not that the cause, by reflex influence, of every earthly ill from stubbed toes to poverty? Then *we* were called in, and found the child suffering with malignant diphtheria. Nobody could ask a better opportunity; and we regret to say that we used it to the full extent. That young man did not practice extensively in that neighborhood for some time thereafter. But—in the fullness of time he was called in to see a patient of our own, who was suffering with typho-malarial fever, and had a sudden change for the worse. Our young friend had his innings, and used it quite as effectually as we had in the preceding case. We suffered much more, because we had more to lose.

No matter how great the provocation, it pays best in the long run to utter no word, give no hint, expressed or implied, that will go to the discredit of a brother physician; but rather to cover up his mistakes and protect his reputation. With competition as severe as now, and human nature in its present state of depravity, this requires a good deal of self-control to accomplish loyally, with brotherly zeal; but it is well worth the pains it cost. And when one lies down to rest, after the old Adam has been conquered, somehow the sleep is sweeter than if the enemy has been smitten hip and thigh.

Annotations.

DR. BENJAMIN WARD RICHARDSON, F.R.S., of London, England, has dedicated the Sixth Volume of his original work, "The Asclepiad," to Dr. Joseph Jones, of New Orleans, Louisiana, in the following words:

To Joseph Jones, M.D., Professor of Chemistry and Clinical Medicine in the Tulane University of Louisiana: A model student of medicine, always seeking, always finding, always imparting with unwearied industry, new and useful knowledge, to the great Republic of Medical Science and Art, this, the Sixth Volume of "The Asclepiad," is sincerely dedicated.

Dr. Richardson is the most eminent living British writer and authority in experimental therapeutics and practical hygiene. He has devoted his life to the elevation of the medical profession, by his extensive original remarks, and to the alleviation of the ills of humanity, by his works on insanity and hygiene.

DR. S. O. L. POTTER, in a letter to the *Pacific Medical Journal*, express his belief that the microbicide for the tubercle bacillus will be found among the volatile anæsthetics. This was suggested to him by his experience with chloroform vapor as a destroyer of micro-organisms in the antrum. He has found chloroform vapor most deadly to the germs of purulent catarrh in inaccessible cavities, of epidemic coryza, hay fever, and similar affections. He has also made some experiments, which lead him to the conviction that the tubercle bacillus may be destroyed and its victim saved, by the daily inhalation of chloroform, carried on in a way to obviate the danger of accident. Inhalations can be kept up for several hours daily, stopping short of general anæsthesia.

TUBERCULOSIS.

THERE is probably no important chronic disease in which our opinions are more frequently sought, more weighty, and more subject to present and future criticism than tuberculosis. The history and character of the disease especially indicate the necessity for early treatment, and this can only follow early diagnosis. Certain things in it also especially call for positiveness and certainty of diagnosis. In spite of the work of years, from Lænnec to Flint, there is no one sign and no group of signs and symptoms which are absolute. Some uncertainty, therefore, always remains, and in the early and therefore most important cases, we must always be, and often remain for some time, uncertain. These are the golden weeks and months. Now, however, doubt is removed, and in the great majority of even early cases we can know certainly what is present. The cases in which it is necessary to be in doubt for more than a week are few and far between, provided the means at command be used. This brings two great advantages: it permits early treatment, before the establishment of that vicious circle of disturbed nutrition which so interferes with success later; and second, what is of great importance, it places the physician at once in the position of "*I know.*" He becomes a dictator, knowing that he is correct, and that he has in his cabinet the indisputable evidence of it. If there is any disease which equals "female neurasthenia" in its need for such dictatorship, it is tuberculosis.

When the profession realizes more fully, and acts upon these things, more lives will be saved.—T. P.

Letters to the Editor.

THE THIRD PLAGUE OF EGYPT AS A DIURETIC.

A FEW days ago I was called to a patient who suffered for two days from retention of urine. I examined the case, found out the cause, and prescribed, as I thought, the appropriate remedy. I left the patient with a light heart, being sure that *après moi le deluge.*

I returned home later, and found an urgent call to come to that patient. I armed myself with hard and soft catheters, and, *à la courier*, hastened to the house of my patient, where I intended to show off my surgical skill.

I forgot to state that my patient is a Russian by birth, lately arrived in this country by third class (steerage), steamship Lord Gough.

Mounting the stairs, I met the mother of the patient, who informed me in an ecstasy of joy that "Blessed be the Lord, *it* came!" I understood the allusion in a moment, and I answered her salute with a broad smile of contentment and self-elation, which denoted as much as to say, "I knew my infusion of digitalis would do the work for me nobly."

Well, here begins my strange tale. I learned from the patient that an hour after the second dose "*it* did not come," and they sent for me, and "*I* did not come." So they tried a home remedy, and "*it* did come, blessed be the Lord." Of course, I was curious to know what kind of home remedy they used. They were reticent about the matter, and tried to evade my questions. My curiosity was so greatly excited that I insisted. The patient told me that they had inserted into the meatus an "unclean thing." Further information I could not elicit. My curiosity was at a high pitch. I commenced to persuade them on the ground of humanitarian principles—that they must reveal to me this nostrum whereby I might save many a human life, and that they would commit a sin by withholding from the world at large such a remedy, which must be both easily applied and cheaply obtained, as, "blessed be the Lord," unclean things in the city of Philadelphia, considering the state of some streets, can be procured without great effort. After a long series of argumentation, I was solemnly initiated into the mysteries of the Russian folk-cure. The remedy was neither organic nor mineral, not even instrumental; it is not to be found in any work of therapeutics; you may scan the works of surgery in vain. It was what is known in Latin as *pediculus corporis*, an exogenous animal, subject of the Russian Czar; a native of third-class (steerage), steamship Lord Gough; or, to put it in simple English, a *louse* was introduced into the meatus, which brought on the flow, as they tell me, in three minutes.

I was curious to learn whether there are any other remedies in their list of diuretics, and the old woman having become talkative, and seeing my earnestness, told me of many herbs used; and in little children, she informed me, they apply to the prepuce the thin film-like coat that envelopes each layer of the onion, which "brings *it* in torrents."

I was almost overcome by this discovery of the genius of folk-cure.

Reasoning logically, I expect that the rat must be used somewhere as an efficient purgative.

C. D. SPIVAK, M.D.

338 Spruce street, Philadelphia.

IRRITATIVE ACTION OF ZINC SULPHO-CARBOLATE.

AN editorial in THE TIMES AND REGISTER highly extols the sulpho-carbolate of zinc in the summer diarrhœas of children.

In malarial dysentery in an adult I made a trial of it; in four grain doses, dissolved in two ounces of water; but it caused vomiting, and my patient complained that it produced irritation of throat and stomach. Now, how do you give it?

In malarial dysentery I am giving one drop of fld. ext. of ipecac. every hour, until it causes vomiting, and then omit a few doses. The ipecac. treatment is fairly satisfactory.

I am much pleased with THE TIMES AND REGISTER. Perhaps more than with any other medical journal that I have ever taken.

A. M. PELTON, M.D.

ASHBY, TEXAS.

[On several occasions I have had the same irritant results from this salt. I believe it is due to the impurity of the drug. The best I have yet seen is Rosengarten's; and when given with bismuth, this has never given rise to irritation in my hands.—W. F. W.]

Book Notices.

DUST AND ITS DANGERS. By T. MITCHELL PRUDDEN, M.D. G. P. Putnam's Sons, New York and London, 1890. Cloth, 16mo, pp. 111; price, 75 cents.

"This little book has been written with the purpose of informing people, in simple language, what the real danger is of acquiring serious disease—especially consumption—by means of dust-laden air, and how this danger may be avoided."

An important object, and a useful book, which physicians should do their best to introduce into every family of sufficient intelligence to appreciate it.

PHYSICAL DIAGNOSIS AND PRACTICAL URINALYSIS. An Epitome of the Physical Signs of the Heart, Lung, Kidney and Spleen in Health and Disease. Edited by JOHN E. CLARK, M.D., Professor of General Chemistry and Physics in the Detroit College of Medicine. Forty-one Illustrations. Cloth, 12mo, 200 pages; price, postpaid, $1.00. Illustrated Medical Journal Co., Publishers, Detroit, Mich.

In this work the object has been to present a systematic and condensed course of Physical Diagnosis and Urinalysis. The portion on urinalysis consists of two parts, practical and reference. The editor believes there is a demand for a short, definite course of organic chemistry, touching on subjects of every-day interest, such as the analysis of urine, chemical and microscopical; the examination of sputa, bile, blood, bacteria, etc.; methods for the quantitative estimation of the more important urinary constituents, normal and abnormal, such as urea, chlorides, sugar, albumen, etc.

EPILEPSY: Its pathology and treatment. Being an essay to which was awarded a prize of four thousand francs by the Académie Royale de Médécine de Belgique, December 31, 1889. By HOBART AMORY HARE, M.D., etc. Philadelphia and London, F. A. Davis, Publisher, 1890. Cloth, pp. 228; price, $1.25.

Dr. Hare may be denominated the champion essayist of the day. He has great industry, good judgment in making selections, and an easy, graceful manner. The present essay is well planned and admirably executed. The author has devoted much and merited attention to recent investigations, while he does not neglect the classics. We have read the book with continuous interest and admiration, seeing scarcely anything to condemn. In fact, the only criticisms we can make are two very small ones; first, an occasional carelessness in proof-reading, as on page 201, line 21, where a sentence is cut in two by a period; second, a certain juvenility of manner, in the way of positive and inelegant expressions, as on page 202, when the author speaks of "curare, whose physiological action makes it about as fit for the treatment of this disease as so much sawdust." The clause "the drug influenced more favorably still petit mal," is not very well expressed for a prize essay.

AT the annual meeting of the Thirteenth and Fourteenth Ward Organized Charity Association, of Philadelphia, Drs. J. R. Partenheimer, Clara T. Dercum, P. N. K. Schwenk and N. H. Ritter, were elected directors.

The Medical Digest.

FRENCH NOTES.

By A. E. Roussel, M.D.

The Results of Castration in Women (M. Keppler, of Venice).—The author removed the ovaries in forty-six women. He obtained thirty nine complete cures, of which, in the greater number, the results were followed for a number of years. The following are the principal physiological conclusions arrived at:

1. After operations performed for a salpingitis or an inflammatory process, there has never followed a flow of blood from the uterus.

2. The conjugate diameter has become progressively shortened, and more especially so when the woman was young; this shortening may reach three centimeters.

3. The uterus has gradually diminished in volume (from eight centimeters to two in the course of years); the vagina is much shorter and more narrow; its mucous membrane has become more pale and the labia major more slender.

4. The breasts have become atrophied and resemble those of man.

5. The pigmentation of the nipples, of the perineum and of the anus, has disappeared, as well as the pathological pigmentation (chloasma). The skin has become of a remarkable whiteness.

6. The tendency to general *embonpoint* has not increased.

7. There has been no modification in either of the hairs, nor of the voice.

8. The sexual appetite has remained the same, and is, if anything, more marked in those cases where the operation has been performed near the appearance of the menses.

9. The operation is not an obstacle to marriage; three of his patients have married happily some years since.

10. Marriage with a castrated woman is the ideal Malthusian union; the only method of applying to the letter the doctrine of Malthus without placing in danger the health or happiness of those interested.

11. In those women operated during youth for inflammatory affections, we do not notice as a result those numerous troubles which we frequently find in women operated upon for uterine fibroids at a more advanced age.

12. Hemorrhages due to uterine fibroids are favorably influenced by castration, but the menopause never follows immediately afterwards.

13. Women operated upon for uterine fibroids when well advanced in life, completely lose their sexual appetite.

The Contagion of Puerperal Fever.—M. Irepant reports a case of puerperal fever which, according to him, was due to an accouchement in a room and in a bed in which another woman died from the same cause twenty months previously. No attempts at disinfection had been made; the following are the facts:

X., living in a village, married a healthy young woman, who became pregnant and went through a normal confinement. Three days afterwards this woman developed symptoms of the fever, and died seven days afterwards.

A few months afterwards X. married again, a strong healthy girl of twenty years. This woman made use of the same room and bed occupied by the first wife. Ten months after this marriage, and after a normal pregnancy, the woman was delivered by Dr. Moriensalle after an ordinary labor. The child was apparently healthy, but died six or eight days afterwards of an enteritis. On the fourth day the mother developed infectious metritis. Thanks to her strong constitution and the intelligent care of her physician, this woman resisted, fought for three months against this infection, passing through the most varied phenomena of the disease, and finally succumbed to the poison. The second wife had a different physician from the first, and this doctor had not seen a case of puerperal fever for a long time, nor did any exist in the neighborhood.

Digitalis in Diseases of Children.—Digitalis and its preparations alone should be employed in diseases of children to the exclusion of digitaline, which is too active.

1. *Infusion of Leaves of Digitalis.*—Infusion of 5 to 10 centigrammes of the leaves in 150 grammes of water.

2. *Extract of Digitalis.*—Under three years of age, 1 to 2 centigr.; from three to five years, 5 centigr.; five to eight years, 10 centigr.

3. *Syrup of Digitalis.*—One to two teaspoonfuls under two years of age; three to four spoonfuls from six to eight years.

Antiseptic Dentifrices.—Salol and resorcine have been recommended by M. Vigier. They may be prescribed in form of elixir or of powder.

1. *Antiseptic Elixir Dentifrice.*—This is a solution of salol or of resorcine in an elixir:

℞.—Resorcine, Salol	āā	2 grammes.
Elixir dentifrice	100	"

2. *Antiseptic Dentifrice Powder* is obtained by the mixture of the following:

℞.—Resorcine	2	grammes.
Salol	4	"
Pulverized oris	40	"
Pulv. carbonate of lime	8	"
Essence of mint	gtt.	x.

Or, we may use the following powder:

℞.—Pulverized charcoal	10	grammes.
Pulverized cinchonia (Grey), Magnesia	āā 5	"
Resorcine, Salol	āā 1	"
Essence of mint	gtt.	v.

Treatment of Infantile Eczema.—1. *Eczema Intertrigo:* Try and remove the cause—generally an acid diarrhœa—then apply fresh conpresses (solution of boric acid 5 per cent., and water equal parts); or, if there is much weeping of the surface use powder with chalk or oxide of zinc. Insist on great cleanliness.

2. *Eczema of the Head:* If the child is fat, modify its diet; if scrofulous, give cod liver oil with phosphorus, or an arsenical preparation—arsenious acid, 0.005 grammes. Boil with 40 grammes of distilled water. Dose: One teaspoonful each day. Suppress all external cause, then soften the crusts with an oily inunction, such as the following pomade:

℞.—Boric acid	1	gr. 50.
Oxide of zinc	5	grammes.
Vaseline	30	"

In eczema squamosum:

℞.—Calomel	1	gramme.
Balsam of Peru	5	"
Wilson's ointment	30	"

3. *Eczema of the Trunk and Members.*—In the squamous forms of eczema, with infiltration of the skin, rub the parts twice daily with a few drops of oil of cade, then powder with starch or apply vaseline. After from two to four days, bathe the parts with luke-warm, soapy water, and after twenty-four hours recommence the treatment with oil of cade.

Tar should not be employed in the eczema of infants.—*Le Bulletin Médical.*

ITALIAN TRANSLATIONS.

By William F. Hutchinson, M.D.

From *La Riforma Medica.*

Prof. Cantani, of Naples, whose authority as a clinician ranks with the highest, recently made some novel and startling statements regarding the origin and treatment of heat in fevers.

According to him, elevated temperature is not the cause of death, and not a dangerous manifestation in acute infectious diseases. Fever is the expression of organic reaction against microbes which invade the system, and, by the change which it causes in the tissues, renders their multiplication impossible. Moreover, increased combustion favors expulsion of deleterious products. Therefore, high temperature is not the symptom to be attacked, but rather the cause that produces this important reaction. So-called antipyretics have no influence on this cause, but, in decreasing thermogenesis, destroy an important factor in cure, frigorific action of tissues. They are nothing else than poisons. That fever is a powerful agent in destroying micro-organisms is shown by the fact that acute febrile infectious diseases are cured spontaneously, while those in which heat is not a chief symptom are not. Consequently, high fever in a strong patient is less dangerous than a lower degree of heat in a weaker person.

The best mode of using heat depressants is the cold bath or other suitable hydrotherapy, which, while increasing surface heat, increases internal thermogenesis at the same time, and, while refreshing, opposes a strong barrier to farther multiplication of bacteria, the true cause of the disease.

Local Application for Diphtheria.—

℞.—Camphor . . . . . ʒv.
Castor-oil . . . . . fʒiv.
Alcohol . . . . . fʒijss.
Carbolic acid (crystals). . . . . ℈iv.
Tartaric acid . . . . . gr. xvj.

M.—Sig. For local application.

—*La Tribune Médicale.*

Ammonium Mixture.—

℞.—Ammon. salicylat.,
Ammonii carb . . . . . āā gr. v.
Spts. ætheris nitrosi . . . . . ♏xv.
Extracti cocæ fluid. . . . . fʒj.
Glycerin . . . . . fʒj.
Liq. ammon. acetat. . . . q. s. ad. fʒss.

M.—Sig. Give every two to four hours, as indicated.

—*Pharmaceutical Era.*

For Acne, Eczema, Etc.—

℞.—Magnesii sulph. . . . . ʒiij.
Ferri sulph . . . . . gr. viij.
Acidi sulphurici arom. . . . . fʒj.
Aquæ menth. pip. . . . . fʒiv.

Sig. Tablespoonful in cup of water, p. r. n.

This is the famous Mistura ferri acidi, as used by Duhring for acne, eczema, etc., accompanied by constipation and anæmia.—*Medical Mirror.*

Hair Tonic for Scalp Diseases.—

℞.—Sodii sozoiodol 2.0
Aq. destillat. 300.0
Spir. Colonieus 20.0

S. Use as a wash for the hair and scalp.

—*Notes on New Remedies.*

Perspiration of the Feet.—The following is advised by Dr. A. Barrett:

℞.—Plumbi acet . . . . . ʒj.
Acet. destillat. . . . . ʒj.
Sp. vin. methyl. . . . . ʒij.
Aq. . . . . ad ʒxxj.

M. Fiat lotio.

Salve for Hemorrhoids.—The following is an excellent salve for hemorrhoids:

℞.—Cocainæ muriat. . . . . gr. xx.
Morphinæ sulph. . . . . gr. v.
Atropinæ sulph. . . . . gr. iv.
Pulv. tannin . . . . . gr. xx.
Vaseline . . . . . ʒj.
Ol. rosa, q. s.

M.—Sig. Apply after each evacuation of bowels. Of course contents of bowels should be kept in soluble condition.

—*Medical Mirror.*

For Pruritus.—The following formulæ will be found very useful as applications:

℞.—Chloral camph. . . . . ʒij.
Bismuth subnit. . . . . ʒij.
Aquæ rosæ . . . . . ad. ʒiv.

℞.—Acidi hydrocyanici dil.,
Tr. opii . . . . . āā ʒij.
Potassii carb. . . . . ʒij.
Aquæ rosæ . . . . . ad. ʒiv. M.

—Reynolds in *Weekly Med. Review.*

Paraldehyde Mixture.—Probably the best mixture for the administration of this remedy is the following:

℞.—Paraldehyde . . . . . fʒij.
Oil of sweet almond . . . . . fʒij.
Chloroform . . . . . ♏x.
Oil of cinnamon . . . . . ♏ij.

Sig. Mix and take undiluted.

We believe Dr. R. G. Eccles was the first to recommend this mixture.—*Pharmaceutical Era.*

Menthol in Pruritus.—This remedy is better than carbolic acid in itching complaints. Use a solution in alcohol, 3 to 6 per cent., say as follows:

℞.—Menthol . . . . . gr. xxiv.
Spt. vini rectif . . . . . fʒj.

M.—Sig. Apply as directed.

Or, as a lanolin salve:

℞.—Menthol . . . . . gr. xx—xxx.
Lanolin . . . . . ʒj.

M.—Ft. ungt. Sig. Apply.

—*Dixie Doctor.*

For Leucorrhœa.—

℞.—Creolin . . . . . gtt. xxx.
Fl. ext. hydrastis . . . . . fʒijss.

Sig. Two teaspoonfuls in a pint of warm water, to be used for one vaginal injection.

As a urethral injection, the following formula is used:

℞.—Fl. ext. hydrastis. . . . . gtt. xxx.
Creolin . . . . . gtt. x.
Aquæ . . . . . fʒviij.

Sig. Use undiluted, as a urethral injection.

—*Journ. de Méd. de Paris.*

PROF. KEEN gave this table to the Jefferson Medical College class, as of use in making the differential diagnosis of the following varieties of tumors:

ENCEPHALOID.	SCIRRHUS	SARCOMA.	ADENOMA.
1. Soft, elastic, not uniform.	1. Hard and inelastic.	1. May be soft and fluctuating, or hard.	1. Soft and elastic.
2. Rapid growth, large size, adhesions early.	2. Slow growth, small size, late adhesions.	2. Growth irregular, adhesions early.	2. Slow growth, no adhesions.
3. Pain slight and wandering; after ulceration severe and fixed.	3. Pain early, sharp fixed and lancinating.	3. Very little pain until ulceration takes place.	3. Pain very slight and neuralgic; menstrual if tumor affects the breast.
4. Veins enlarged.	4. Veins slightly enlarged.	4. Veins slightly enlarged.	4. Veins normal.
5. Ulcerations deep, foul, undermined and bleeding.	5. Ulceration deep, edges hard and abrupt.	5. Ulceration sooner or later quite deep.	5. No ulceration.
6. Glands involved early.	6. Glands involved late.	6. Rarely, if at all, involved.	6. Glands never involved.
7. Occurs at any age, usually before 45th year.	7. Usually occurs after 40th year.	7. Occurs in adult middle life, 20th to 40th year.	7. Occurs from 20th to 30th year, usually.
8. Occurs most frequently in the breast, testicle and uterus.	8. Breast, uterus, stomach.	8. Connective tissue anywhere.	8. In breast or other glands.
9. Death occurs in from 9 to 12 months.	9. Death in from 9, to 18, to 36 months.	9. Death occurs early or late, simply a matter of time.	9. Never kills.
10. If in breast there is no retraction of nipple.	10. There is retraction of nipple.	10. No retraction of the nipple.	10. No retraction of nipple.
11. Family history is bad.	11. Family history is bad.	11. Family history good.	11. Family history good.

—*Coll. and Clin. Record.*

A FEW months ago Dr. Arnold, of Zug, pointed out that compressed tablets of antipyrine, antifebrin, and other medicaments, sometimes passed the patient's digestive canal unchanged. Referring to his note, the *Schweizerische Wochenschrift für Pharmacie* points out that the drawback can be easily prevented by the manufacturer; it is sufficient to interpose a layer of powdered sugar or tragacanth between the layers of the tablets. The purchaser should always ascertain by experiment whether or not the tablets are soluble in water. If they are not so, they are, of course, useless.

MANSLAUGHTER BY A FAITH HEALER.—The practice of faith healing has received a severe check, if not its death blow, in the city of Toronto. A certain well-known citizen, who had for some time been the subject of diabetes, and had been dieted for it, thought he would give himself the benefit of the newest fashion, and accordingly placed himself in the hands of a Mrs. Stewart, one of the apostles of the new art. Being by her instruction freed from all dietetic restrictions, he speedily died of diabetic coma, and an inquest being held the jury found that "he came by his death through the gross ignorance of Mrs. Stewart, who undertook to cure him of his disease, in not advising him to continue the restricted diet prescribed by his former physician." Mrs. Stewart is consequently now awaiting her trial for manslaughter. We forbear to comment upon a case which is still *sub judice*.

USES OF COFFEE.—It is asserted by men of high professional ability that when the system needs a stimulant, nothing equals a cup of fresh coffee. Those who desire to rescue the drunkard from his cups will find no better substitute for spirits than strong new-made coffee, without milk or sugar. Two ounces of coffee to one pint of boiling water makes a first-class beverage, but the water must be boiling, not merely hot. Bitterness comes from boiling too long. If the coffee required for breakfast be put in a granitized kettle over night, and a pint of cold water be poured over it, it can be heated to just the boiling point, and then set back to prevent further ebullition, when it will be found that while the strength is extracted, its delicate aroma is preserved. As our country consumes nearly ten pounds of coffee per capita, it is a pity not to have it made in the best manner. It is asserted by those who have tried it that malaria and epidemics are avoided by those who drink a cup of hot coffee before venturing into the morning air. Burned on hot coals, it is a disinfectant for a sick-room. By some of our best physicians it is considered a specific in typhoid fever.—*The Epicure.*

NEW BLOOD CELLS.—The latest discovery is that of a new blood cell, by Dr. Alexander Edington, of Edinburgh, a surgeon and bacteriologist of considerable repute, who has devoted much time to the study of the morphology of the blood. This new cell, Dr. Edington calls an "albocyte." It is a spherical, colorless cell, of about one-third the diameter of the ordinary red blood corpuscle, of which it is an early form.

The whole of Dr. Edington's views regarding the blood cells may be summed up as follows:

Starting with white blood corpuscles, he finds that in their earlier life they contain one, or at most two nuclei, which number, after a certain period of development, is increased to four. The discharge of these nuclei from the cell results in the formation of "free," or "daughter" nuclei, of which some go in to the development of fresh white blood corpuscles, while others become multinucleated cells, also allied to white blood corpuscles, but having distinct functions to perform. To this cell the discoverer gives the name of matricyte, and it, after increasing in size, discharges its numerous nuclei, and then forms, what he calls, the new cell—the "albocyte." This gradually enlarges, takes up hæmoglobin, and eventually is transformed into the perfect red blood corpuscle. The arrangement, then, according to Dr. Edington, is: (*a*) The white blood corpuscle; (*b*) the daughter nuclei; (*c*) the matricyte; (*d*) the albocyte; (*e*) the red blood cell; (*f*) the granular bodies called hæmatoblasts.

These latter bodies were named by Hayem, and consist, according to him, of granular matter originating in the white cell. They are concerned, together with the white cell, in the formation of fibrin.

—*Canada Lancet.*

SARCOPHAGY IN SCOTLAND.—When Bruce, the African traveler, first published his anecdotes respecting the customs of the Abyssinian and Nubian tribes, they were listened to with incredulity, and were severely ridiculed by the Grub street writers of the day, and it is told that he had to resort to strong measures to convince a gentleman in Edinburgh that it was possible for a human being to eat raw meat; but no scepticism on that point can exist in Scotland at the present day, for George Muir actually died in the streets of Castle Douglas, on September 26, in consequence of his ravenous partiality for that particular viand. He went into the shop of Messrs. Ballard Brothers, butchers, and got a small piece of raw beef, which he put in his mouth. After leaving the shop he suddenly fell on the pavement, and a medical man who was summoned extracted the piece of raw beef, which weighed three ounces, from the back of his throat; too late, however, for it had choked him. The man seems to have labored under the belief that a hunch of raw meat is an agreeable and restorative titbit. Underdone steaks have often been regarded in the same light, but a semblance of cooking has always hitherto been insisted on.

—*Brit. Med. Jour.*

PRACTICAL ASEPSIS.—*Asepsis of the Hands.*—Frequent washing of the hands, with or without antiseptics, irritates the skin, producing redness and chapping. It is therefore advisable, after washing and drying the hands, to rub them with one of the following pomades, which are recommended by Prof. Liebreich:

1. ℞.—Lanoline	. . . . .	5	grm.
Vanilline	. . . . .	0.01	"
Essence of rose	. . . . .	1	gtt.
2. ℞.—Lanoline	. . . . .	100	grm.
Paraffine	. . . . .	25	"
Vanilline	. . . . .	0.01	"
Essence of rose	. . . . .	1	gtt.

Asepsis of the Sick Room.—Sevestre advises the use of the following solution, which may be sprayed or evaporated by boiling:

℞.—Thymic acid	. . . . .	5	grm.
Carbolic acid	. . . . .	10	"
Alcohol	. . . . .	100	"
Water	. . . . .	885	"

Asepsis of Utensils and Instruments.—It is sufficient to dip utensils and instruments in a boiling solution of carbonate of sodium (30 grm. per litre). The same solution may be used to disinfect sputa and to clean cuspidors and vessels.—*Pharmaceutical Era.*

PUERPERAL ECLAMPSIA.—A New Zealand physician, Henry Teevan, relates, in *The British Medical Journal*, the following cases of puerperal eclampsia, which occurred during the last twelve months:

"H. C., aged thirty-eight years, multipara, about seven months pregnant: convulsions. Treatment by subcutaneous injections of pilocarpin, gr. $\frac{1}{10}$. Inhalations of chloroform, venesection, with no amelioration. Death in nine hours. Premonitory symptom: diarrhœa. No œdema of the extremities. Albumen in urine during the convulsions.

"H. L., aged twenty-six years, primipara, also about seven months pregnant: convulsions. Treatment as above, with no beneficial result. Death in thirteen hours and a half. No premonitory symptoms. Neither of the patients was able to swallow, but a rectal injection of chloral and bromide was administered to the second one. As labor had set in, she was delivered with forceps of a dead fœtus. There was no œdema.

"Mrs. H., primipara, was confined at full time; labor normal. Immediately afterwards she complained of intense occipital pain. Convulsions came on about an hour and a half afterwards. I determined to give opium a trial, as my other cases had ended so badly. Injected her with morphine, gr. $\frac{1}{4}$, and atropine, gr. $\frac{1}{150}$, which had the effect of stopping the convulsions for half an hour. I had just given her a dose of chloral and bromide, gr. xx of each, when another convulsion set in, upon which I again gave a subcutaneous injection of morphine, gr. $\frac{1}{4}$, with the result that she had no further convulsion, and slept the whole day, being roused only to take the chloral and bromide mixture every four hours. Next day she had no recollection of anything after the birth of the child. I attribute the successful result more to the opium than to the mixture. She had premonitory symptoms of diarrhœa and œdema for weeks before the onset of labor."

BROMOLE.—As a surgical dressing after amputations bromole will be found superior to any antiseptic known to the profession. My experience with it is confined to the amputations of fingers and toes, but the results obtained by me were so flattering that I am satisfied it will meet all expectations in the larger operations. The form in which I use it is as follows:

℞.—Bromole	. . . . .	ʒij.
Ol. olivæ.	. . . . .	ʒviij. M.

Cotton-seed oil, or any other kind of fixed oil, may be substituted for the olive oil.

As a dressing for wounds, or foul and indolent ulcers, I generally use an ointment, as follows:

℞.—Bromole.	. . . . .	ʒj.
Ung't. simplicis	. . . . .	ʒj. M.

Or it may be sprinkled on the ulcer in the form of powder, with equally good results.

As a local application in diphtheria this compound produces excellent results when the glycerine solution is applied to the fauces. It immediately stops the foul odor in malignant forms of diphtheria, and destroys the exudation formed on the hardened glands. If the medicine is applied frequently, the indurated glands soften rapidly, and all further exudation of membrane is stopped. The same can be said of its local application in scarlet fever. I prefer this compound to nitrate of silver or any other medicine that I have used.

The formula I use is as follows:

℞.—Bromole.	. . . . .	gr. xx.
Glycerini	. . . . .	ʒj.

M. Sig.—Apply with a probang.

I have also used this compound successfully in croupous and tuberculous laryngitis by means of inhalation, for which I use an ordinary croup kettle; also in capillary bronchitis following measles. I generally put about ten grains of bromole in the kettle.

Internally I have used it in cholera infantum, typhoid fever, and abscess of the lung, the result of which I shall report in a future article. The dose given for internal administration was one-sixteenth to one-fourth of a grain.—*Amer. Pract. and News.*

AN institution has been founded in Paris which is likely to prove a blessing to foreigners who may become ill while sojourning in the gay capital. A Danish lady, Frokur Neilson, is the originator of this plan to supply for the sick trained nurses speaking the principal languages. These nurses will be sent to all parts of France and even to other contries when desired. In connection with the institution is a school for the training of the nurses.

DR. DAVID D. STEWART'S address is 1231 Walnut street, instead of 1310 Walnut street.

SEVEN Philadelphia dealers in oleomargarine have been sued for selling adulterated butter.

DR. W. P. SNYDER has been nominated for candidate for the Assembly for Chester county's Northern District.

RESIDENTS of Philadelphia's twenty-seventh ward complained to the Board of Health about the Mill Creek nuisance.

THE Medical Profession of Louisiana has again failed with the State legislature in the matter of a law to regulate practice.

SIXTEEN HUNDRED AND EIGHTY-FOUR students of pharmacy were enrolled in the four Italian schools during the past year.

DR. CHARLES L. HUBBELL died suddenly of heart disease on October 6 in his room at the Taconic Inn, Williamstown, Mass.

DR. WILLIAM BOYLE has been appointed Assistant Chief Surgeon, at Atchison, Kas., in the place of Dr. Holland, deceased.

PHYSICIANS do not often have the honor of upsetting thrones, but the doctors attending the King of Holland have just pronounced him unfit to reign.

DR. JAMES KERR was elected a member of the hospital staff of the Baltimore Emergency Hospital, and Mr. H. L. West a member of the Board of Trustees.

IOWA physicians are interested in a dropsical patient who has been tapped one hundred and forty-one times, and goes about the household duties notwithstanding.

PROFESSOR METSCHNIKOFF, of Odessa, the distinguished Russian bacteriologist, has been appointed head of the Pasteur Institute in Paris, under the general direction of M. Pasteur.

AT the opening of the regular session of the Medical Department of the University of the City of New York, September 30, Professor William H. Thomson delivered a lecture on the Medical Aspects of Mental Discipline.

MEDICAL CONGRESS IN RUSSIA.—The fourth congress of the Society of Russian Medical Practitioners will be held at Moscow, the day of meeting being fixed for January 3, 1891. The work is to be done in twelve sections.

DR. JUDSON DALAND read a paper on The Medico-Legal Aspects of Hypnotism at the fifty-first stated meeting of the Medical Jurisprudence Society of Philadelphia, at the hall of the College of Physicians, last Tuesday.

IT is reported that Dr. E. B. Sangree, of the Medico-Chirurgical College, is to be married to Miss Ella Russell, in December. Miss Russell is a step-daughter of Mr. L. H. Hall, a well known business man in New York and Philadelphia.

FAMILIARITY breeds contempt in the case of those whose official duties bring them in contact with lunatics; but the killing of Dr. Lloyd by an escaped patient serves to call attention anew to the folly of disregarding the threats of these persons.

DR. G. B. CLARK, Home Rule Member of Parliament for County Caithness, Scotland, arrived in New York last week. He comes as a representative of the Highland League to inquire into the condition of the crofters who emigrated from Scotland to Manitoba.

PHYSICIANS pay more attention to athletics since massage has demonstrated the curative value of exercise. Among the representatives of the Baltimore Athletic Club to the annual meeting of the Amateur Athletic Union we note the name of Dr. B. M. Hopkinson.

DR. WETHERILL still keeps at his good work of hunting out insane people who are improperly cared for and having them sent to asylums. The last trip revealed two sisters of one family and two brothers of another being kept, in an insane state, by their parents.

THE proceedings of the recent Berlin Congress, which include more than two hundred addresses and discussions, will be published in full in a large work, which will appear in separate parts. It is expected that the first part will be ready in the course of the autumn.

DURING September the Children's Aid Society, 127 South Twelfth street, found situations for forty-five mothers at service, each taking one child with her. There were also twenty-one children placed in private families to board, and eleven were placed in private families on trial.

PROFESSOR CHARLES RICHET states in the *Progrès Medical* that fifteen grains of sulphate of quinine, administered two hours, or four hours at the most, before embarking, will completely free even sensitive subjects from the horrors of sea-sickness. The experiment is well worth trying.

THE Kensington Hospital for Women, of Philadelphia, has purchased the property at 136 Diamond street, and will remove there shortly. When the alterations are completed the entire cost will be about $20,000. Double the present number of patients will be accommodated. Dr. Charles P. Noble was re-elected surgeon-in-chief.

DR. WALTER M. FLEMING, a prominent New York doctor, has been charged by Mrs. Stephani with extortion and grand larceny; in connection with her son's case. Dr. Fleming is one of the committee appointed to investigate the alleged insanity of the young murderer; and is said by Mrs. Stephani to have received over $5,000 for supposed expenses.

THE *Brooklyn Medical Journal* refers in very complimentary terms to Dr. Mattison's plan of treating drug-addiction. The Mattison method originated from clinical studies upon patients treated in his own home; it may be termed the only distinctively American method, and has great advantages over the more primitive methods of Levinstein and Erlenmayer.

At last week's meeting of the Board of City Trusts, Drs. Frank Fisher, Samuel D. Risley, and Edward Jackson were appointed physicians to the Wills Hospital. Some discussion was raised over the confirmation of all the physicians named, who were reported by the Committee on Minor Trusts, but the resolution of the committee was finally adopted.

To smooth out a wrinkled diploma, apply a coating of hot paraffin to the back, and before it is entirely cold smooth out the wrinkles with a common smoothing iron; place the diploma between two clean panes of glass larger than the diploma, and weight it down for several days before replacing in the frame.

—*Meyer Bros. Druggist.*

Medical examiners were on October 10 appointed in the Pension Office as follows: Moor S. Falls, of Louisiana; James B. Hungath, of Kansas; D. M. McPherson, of Arizona; Henry La Motte, of Pennsylvania; Jacob F. Raub, of Pennsylvania, and Henry O. Witman, of Pennsylvania. Dr. Falls is a son of A. J. Falls, of this city, and resides at 1200 Eighteenth street.

Relatives of Robert Hardie are said to doubt the truth of the account of his death, given by his brother-in-law, Dr. Francis L. Haynes. It will be remembered that Dr. Haynes narrowly escaped from the Indians at the time Hardie was killed. The latter's relatives now tell a story which indicates a desire to throw suspicion on Dr. Haynes. The tale sounds very much like an emanation from the addled brain of a devourer of very cheap fiction.

During September the work accomplished at the Women's Hospital comprised the following: Patients treated in wards, 96; discharged, 37; new patients treated in clinics, 487; gynecological, 179; medical, 81; surgical 42; eve, 69; ear, throat, and nose, 43; electrical, 57; dental, 16; visits to morning clinics, 2,019; births in the house, 7; births in out practice, 3; operations in house, 16; operations in morning clinic, 29, one of the latter laparotomy; prescriptions compounded, 2,538; nurses in hospital service, 48.

It is with pride that we notice the development of the silk industry in our State. The display at the State Fair was creditable and in every respect equal to the exhibit of States much older in this production. To Dr. L. A. Buck and his estimable wife belongs the credit of the progress of this institution. The plant is located at Peabody, Kas. In conversation with the doctor, he told us that Kansas silk in New York markets brought one dollar per pound more than any other silk in the market. We take off our hats to Kansas.—*Kansas Med. Journal.*

One physician of Buffalo has brought suit against another for twenty-five thousand dollars' damages for calling him a quack. The chief interest in the case lies in the fact that this much-used and often-abused word is now likely to be defined judicially. The plaintiff had called the defendant in consultation on a case of hernia, which he had treated by electricity. The relations between them became strained, for the plaintiff says that at a meeting of the County Medical and Surgical Society in the Iroquois Hotel on September 2, the defendant spoke of him thus: "The use of electricity is now practised by a notorious quack of Buffalo for the cure of hernia. This quack pronounced the patient cured of hernia after treating him, and a few days afterward the patient was taken with symptoms of strangulation."

—*Boston Med. and Surg. Journal.*

The Absorption of Fat.—Minkowski has found that after extirpation of the pancreas animals entirely lost the power of absorbing fat, except in the form of milk, though if pig's pancreas were mixed with the food the fat was digested and retained. He therefore concludes that the secretion of the pancreas is, if not the sole, at any rate an essential factor in the absorption of fat, reducing it to an emulsion, or a state of physical and mechanical division and suspension similar to that in which it exists in milk.

A charming little fair was held at the residence of Dr. E. E. Montgomery, 1818 Arch street, on Friday afternoon and evening of last week by the "Little Samaritans" for the benefit of the Medico-Chirurgical Hospital. This organization was started by four little girls, Mabel de Kinder, Susie Montgomery, Delia Stewart and Jean Plumly, and the officers at present are Charles Bush, *President;* Delia Stewart, *Vice-President;* Susie Montgomery, *Secretary;* and Mabel de Kinder, *Treasurer*. The fair was quite a success, and we wish the "Little Samaritans" all the success in the world. The fair netted over $200.

At last week's meeting of the Bureau of Charities and Correction, some very handsome needlework, done by the patients in the Insane Department of the Almshouse, was shown to the Board. The materials were sent to the Almshouse some time ago by Mr. John Wanamaker, and as the nurses report a beneficial effect on the patients, contributions of such articles would be of great use. Miss E. Summers was appointed head nurse in the Children's Department. The Almshouse at present contains 2,772 inmates. In the hospital there are 874 patients, and in the outwards 609 men and 405 women, a total of 1,013.

Dr. Rollin B. Gray, of Saratoga, gives, without fee, this prescription for escaping the hypnotizer:

"First, remove and remain out of the physical presence of the person who exerts the power to control. Then submit to the hypnotic influence of another hypnotizer, who should gain as complete suggestive control as possible, and then dismiss the subject—by his power restoring to the hypnotized his own personality and will-function. Thus the victim is slipped from under the control of one superior will (which, it is assumed, is understood) to that of another, who, in turn, restores to him his own personal sovereignty, and bolsters him up in it. But the subject must ever thereafter avoid the presence of the first hypnotizer." One might also hypnotize a too-familiar hypnotizer with a small club or something.

Is it Charity?—During the year 1889 it is stated that over one hundred thousand patients were treated at the Vanderbilt Dispensary. The total number of patients treated at all the dispensaries of this city, according to the official lists in the *Medical Register*, was, in 1889, about three hundred and fifty thousand, exclusive of those treated in the dispensary referred to. If the figures are correct, then within two years the medical paupers of the city have suddenly increased from three hundred and fifty thousand to nearly half a million. In other words, one out of every three or four inhabitants of the city receives medical advice gratis. Curiously enough, while the annual catalogue of the College of Physicians and Surgeons announces one hundred and two thousand patients treated in 1889 at the dispensary referred to, the *Medical Register* gives the number as twenty nine thousand seven hundred and twenty-three. The same authority credits the Eastern Dispensary with the largest number of

patients, viz., sixty-one thousand two hundred and twenty eight, and after this the New York Dispensary, forty-four thousand three hundred and thirty-one, and Bellevue, thirty-nine thousand eight hundred and eighty-nine. Whatever be the true figures, it is evident enough that our medical charities, so called, are growing apace.—*Med. Record.*

THE Board of Trustees of the Rush Hospital for the Treatment of Consumption met last week and elected the following officers: Hon. William M. Ashman, President; Mr. William C. Bullitt, Vice-President; Mr. Joseph De F. Junkin, Secretary; Mr. Nathaniel E. Janney, Treasurer. The following Medical Staff were also elected: Harrison Allen, M.D., Laryngologist; Edward Jackson, M.D., Ophthalmologist; R. Alexander Ramsdell, M.D., Otologist; Henry R. Wharton, M.D., Surgeon; John Guiteras, M.D., Pathologist. The following were elected Consulting Physicians: Alfred Stille, M.D., J. M. DaCosta, M.D., James Tyson, M.D., Roland G. Curtin, M.D.

It was determined, also, to at once begin active work, and a committee was appointed to procure a suitable site for the new hospital.

DR. ROTHROCK, of the University of Pennsylvania, has frequently conducted exploring expeditions of students, giving the latter valuable instruction as well as enjoyment, and this fall will make an expedition to the West Indies. His yacht Whitecap is to leave this city about the 15th of this month with stores and the appliances to be used in collecting objects of natural history. The party of naturalists will join the vessel at Fernandina, Florida, and sail thence for the West Indies about the first of next month, taking with them apparatus for deep sea dredging, as well as for collecting on land. The expedition is undertaken under the auspices of the University of Pennsylvania, and is expected to enrich the museum of that institution, besides leading to similar expeditions in succeeding years. Much original material has already been carried from this continent to European museums, and it is now proposed to systematically explore this continent for the benefit of our home institution, and in doing this exceptional opportunities will be afforded for study in the laboratory of nature, and for healthful recreation.

A SURGEON states that of 5,000 decrepit or aged soldiers that have been brought under his notice, fully 80 per cent. were suffering from heart disease, in one form or another, due to the forced physical exertion of the campaigns, and he predicts that as large a percentage of the athletes of to day will be found, twenty-five years from now, to be the victims of heart disease, engendered by the muscular strains that they force themselves to undergo. With regard to the effect of exercise on the prolongation of life, it may be said that there are more people living in France to-day who have passed the age of sixty than there are in England, the home of athletic sports; and there is probably no nation in Europe more averse to muscular cultivation for its own sake than is the French. Great athletes die young, and a mortality list of Oxford men who have rowed in the "varsity" races, published a few years ago, showed that a comparatively small percentage of them lived out the allotted time. A physician has compiled some very elaborate statistics to demonstrate that men of thought live, on an average, three years and a half longer than men in the ordinary vocations of life.—*Chicago News.*

FRANKLIN INSTITUTE LECTURES.—The Franklin Institute provides, every year, a course of lectures of marked value to young mechanics who desire to improve their minds and advance themselves in their profession. These lectures are given on Monday and Friday evenings of each week, from November 10 to February 27. The programme for the season of 1890 has just been issued, and embraces lectures by Prof. Persifor Frazer, Mr. C. J. Hexamer, Dr. H. Hensoldt, of Columbia College; Prof. Edward D. Cope, Dr. Bruno Terne, Commander F. M. Barber, U. S. N.; Prof. G. G. Groff, Dr. L. Webster Fox, Captain F. A. Mahan, Corps of Engineers, U. S. A.; Mr. J. C. Trautwine, Prof. William D. Marks, Mr. Fred. E. Ives, Dr. A. Victoria Scott, Mr. John Carbutt, Dr. Louis Bell, Prof. J. W. Richards, of Lehigh University; Prof. F. W. Clark, of Washington; Mr. C. J. H. Woodbury, of Boston; Prof. Elihu Thomson, Mr. F. Lynwood Garrison, Dr. E. C. Kirk, Mr. Park Benjamin, Mr. John Birkinbine, Mr. George F. Kunz, Mr. Oberlin Smith, Mr. Horace L. Piper, Dr. H. A. Slocum, and Mr. Walter C. Kerr. These gentlemen are nearly all experts on subjects they have selected, and the lectures, when they admit of it, will be illustrated by lantern views and experiments.

THE activity of Baltimore women in all good work may be judged by the list of societies participating in the conference at Levering Hall last Tuesday. The object of the meeting was the dissemination of information in regard to the work being done by women's societies and the charitable institutions managed by women. Among the societies and institutions represented were the King's Daughters, Young Woman's Christian Association, Female Christian Home, McAll Mission, Pundita Ramabai Circle, Female House of Refuge, Home for Fallen Women, Female City Mission, Aged Men's and Women's Home, Home for Confederate Widows, Home of the Friendless, Nursery and Child's Hospital, St. Vincent's Infant Asylum, Baltimore Or-

phan Asylum, Johns Hopkins Colored Orphan Asylum, Shelter for Colored Persons, Ladi s' Aid Society of Boys' Home, Woman's Work in the Free Summer Excursion Society, Woman's Exchange, Decorative Art Society, Association for the Advancement of Women, Hebrew Ladies' Aid Society, Home for Incurables, Charity Organization Society, Woman's Christian Temperance Union, Children's Country Home, Home for Mothers and Infants, Kindergarten Association, Girls' Friendly Society, Myrtle Assembly, K. of L., St. Joseph's House of Industry, Johns Hopkins Hospital School for Nurses, Woman's Fund for Medical School of Johns Hopkins University, Hospital Relief Association, and the Hospital for the Women of Maryland.

PATENTS, ETC., issued October 7, 1890:—

Back-support and shoulder-brace	M. E. Thomas	Batesville, Ark.
Inhaler	Dow & Warren	Wooster, O.
Liniment	W. Doppelmayer	Sherman, Tex.
Liniment	Snow & Johns.	Washington, D. C.
Liniment-pad	B. T. Jacobs	Stapleton, N. Y.
Head-protecting respirator	J C Jensen	Denmark, Kans.
Amputating-saw	C. H. Truax	Chicago, Ill.
Tonic beverage	R. Rambousek	St. Louis, Mo.
Truss	J. F. Newton	Bardstown, Ky.

TRADE-MARKS.

Liniment. (The representation of frogs playing leap. frog.)	Freure Bros.	Brooklyn, N. Y.
Medicine for private use. (The words "Pleasure-Friend.")	H. W. Faber	St. Louis, Mo.
Dental preparation. (The word "Obtundo.")	T. P. Morey	Bangor, Me.
Remedy for throat and lung diseases. (The word "Psychine.")	Whitcomb & Sayre	New York, N. Y.
Cod-liver oil. (The words "Oxygenized Pure Cod-Liver Oil" and the fac-simile signature of "T. A. Slocum.")	Whitcomb & Sayre	New York, N. Y.
Druggists' sundries, surgical goods, etc. (The representation of a United States shield having on it at the top the words "High Grade.")	Cleveland Rubber Co.	Cleveland, O.
Extracts, essences, etc. (The word "Cha lenge.")	E. R. Durkee & Co.	New York, N. Y.
Restorative preparation for diseased eyes. (The words "Veazie's Eye Restorer.")	Bassett & Brumaghim	Albany, N. Y.
Toilet-masks for the complexion. (The representation of a female head with a mask placed in position to the face and secured by elastic bands	J. E. Hetherington	New York, N. Y.
Remedy for the cure of blood diseases. (The portrait of Mrs. Elizabeth Simington.)	E. Simington	Dickens, Iowa.

LOCK BOX 76, WASHINGTON, D. C.

THE MEDICO-CHIRURGICAL NOTES.

THE seniors had a veritable love-feast at their class election, something unusual for a body of young men having arrived at that period of their college life when the supreme dignity of seniority inflates each with an egotistical estimate of self. The retiring president, Mr. Watt Foster, of Pittsburgh, Pa., conducted the proceedings with fairness and promptitude. The president-elect, Mr. Joseph Cramp, of Philadelphia, assumed the mantle of office with a few brief and well chosen remarks. The other officers elected were: Mr. Foster Quail, *Vice-President;* Mr. August Trapold, *Secretary;* Mr. Victor T. Roth, *Treasurer.* Let the other classes, in this respect, follow the example of the class of '91.

The class of '91 starts in on her third heat undeminished in size and vigor. In point of number, and excellence too, she will pass under the discriminating wire to be thrown across her path on the ides of March, unsurpassed by any former class.

The class of '93 is a set of handsome young fellows. What lies beneath their well fitting hats remains to be demonstrated. If it be true that "the apparel oft proclaims the man," and we don't doubt it, then the M. C. C. has reason to be proud of her latest born.

The juniors have returned bright as the morning dew. The gusto with which they give their college yell is worthy of a band of whooping Kickapoos.

Prof. Keyser's eye clinic, we venture to say, is certainly unsurpassed, if not unequaled, by any other clinic of its kind in the country. Rarely does he hold a clinic but what he has, in addition to a great number of various affections of the eye, one or more operations for cataract, removal of the ball or its contents.

Notwithstanding the inconvenience necessarily attending the rebuilding of our hospital, the college clinics are well sustained.

Dr. Shimwell is going to give to the seniors a very practical course in operative surgery. That the students may have an idea of the touch and conduct of living tissue before the scalpel, and of the effect of air upon the contents of air-tight cavities, such as the abdomen, he will have them do a few abdominal operations upon living animals. The frequency with which the surgeon is now required to enter the abdominal cavity for various causes, makes the giving of instruction and practice to the undergraduates in this class of operations as imperative as in amputations upon the cadaver. Though a few dogs perish, the skill and knowledge acquired by the student may enable him as a surgeon to save many a human life.

It is to be hoped that Prof. Anders will carry out his intention of taking sections of the senior class through the wards of the various hospitals with which he is connected. The Professor is extensively read, and is a most intelligent clinical observer. We are eager to follow so able an instructor to pick up the grains of practical truth he would disseminate for all at the bedside of the sick.

A PIPE AND A DICTIONARY.

THIS is the weed nicotian.

This is the pipe with stem of reed
Which held the stuff that's called the "weed."

This is the match with phosphor end
Which lighted the tube with graceful bend,
Packed with the shrub Virginian.

This is the man bereft of hair,
Whose sulphurous fumes defiled the air,
As he started his meerschaum brown, flavescent,
Filled with Raleigh's gift herbescent.

This is the smoke that rose from the clay
In the lips of the fiend who puffed away,
While the flame on the end of the wooden splint
Ignited the powder which gave the tint
To the bowl of the instrument fuliginous,
Stuffed with America's plant indigenous.

This is the salivary stain,
Produced by the glands of the beast inane,
Whose work pulmonic made fumes carbonic
Which rose with those of the fusee bright,
Whose fiery tip had served to light
The capsule charged with poisonous drug,
Known by the name of "navy plug."

This is the stone which tells the fate
Of him whose death expectorate
Was caused by the herb of powers asthenic,
Consumed in a process oxygenic,
Begun by the spark of stick pyrogenous,
Applied to a briar-wood pipe exogenous,
Of which the smoke is poison slow,
Whose name it takes from Jean Nicot.

—James F. Babcock, in the *Boston Transcript.*

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Changes in the Medical Corps of the U. S. Navy for the week ending October 11, 1890.

BRAISTED, WM. C., Detroit, Mich. Appointed an Assistant-Surgeon in the United States Navy.

WALES, P. S., Medical Director. Detached from temporary duty as member of Medical Examining Board.

AMES, H. E., Passed Assistant-Surgeon. Detached from temporary duty as member of Medical Examining Board.

HERNDON, C. G., Surgeon. Ordered to Naval Hospital, New York.

PERSONS, R. C., Surgeon. Detached from Naval Hospital, New York, and wait orders.

SCOTT, H. B., Passed Assistant-Surgeon. Ordered before the Retiring Board.

PRICE, A. F., Surgeon. Detached from Naval Dispensary, Washington, D. C.

ANDERSON, FRANK, Passed Assistant-Surgeon. Ordered to Naval Dispensary, Washington, D. C.

WHITE, C. H., Medical Inspector. Ordered to hold himself in readiness for duty to U. S. S. "San Francisco."

BRAISTED, W. C., Assistant-Surgeon. Ordered to Army and Naval Hospital, Hot Springs.

SPRATTLING, L. W., Assistant-Surgeon. Ordered to hold himself in readiness for orders to the U.S.S. "San Francisco."

SIEGFRIED, C. A., Surgeon. Ordered to the U. S. Trainingship "New Hampshire."

BLACKWOOD, N. P., Assistant-Surgeon. Detached from duty in the Bureau of Medicine and Surgery, and granted leave of absence.

STONE, L. H., Assistant-Surgeon. Detached from the U. S. S. "New Hampshire," and wait orders.

EDGAR, JOHN M., Passed Assistant-Surgeon. Ordered to hold himself in readiness for duty on the U. S. S. "San Francisco."

GARDNER, J. E., Passed Assistant-Surgeon. Detached from the "Albatross," and wait orders.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service from September 8, 1890, to October 4, 1890.

HUTTON, W. H. H., Surgeon. Detailed as chairman, Board of Examiners, October 2, 1890.

LONG, W. H., Surgeon. Detailed as member, Board of Examiners, October 2, 1890.

PURVIANCE, GEO., Surgeon. Granted leave of absence for thirty days, September 10, 1890.

GODFREY, JOHN, Surgeon. Detailed as recorder, Board of Examiners, October 2, 1890.

WHEELER, W. A., Passed Assistant-Surgeon. To proceed to New Orleans, La., for temporary duty, October 3, 1890.

BANKS, C. E., Passed Assistant-Surgeon. Granted leave of absence for twenty days, October 3, 1890.

AMES, R. P. M., Passed Assistant-Surgeon. To proceed to New Orleans, La., for duty, September 13, 1890.

PETTUS, W. J., Passed Assistant-Surgeon. To proceed to Vineyard Haven, Mass., for temporary duty, October 1, 1890.

HUSSEY, S. H., Assistant-Surgeon. To proceed to New Orleans, La., for temporary duty, September 19, 1890. To proceed to Norfolk, Va., for temporary duty, October 3, 1890.

WERTENBAKER, C. P., Assistant-Surgeon. Granted leave of absence for twenty days, September 12, 1890.

PERRY, J. C., Assistant-Surgeon. Upon expiration of leave, to rejoin station at Mobile, Ala., September 29, 1890.

YOUNG, G. B., Assistant-Surgeon. To proceed to Memphis, Tenn., for temporary duty, September 13, 1890. To rejoin station, St. Louis, Mo., when relieved at Memphis, Tenn., October 3, 1890.

PHYSICIANS' FAVORITE PHAETON,

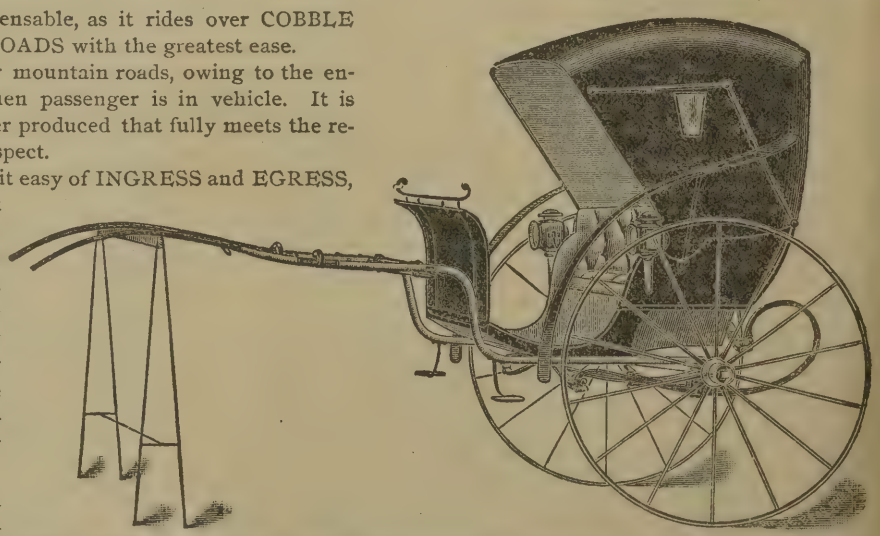
Guaranteed to be Absolutely Free from Horse Motion or Weight on Animal.

THE CHADWICK TWO WHEELER.

For Physicians' use it is indispensable, as it rides over COBBLE PAVEMENTS or FROZEN RUT ROADS with the greatest ease.

It is especially adapted to hilly or mountain roads, owing to the entire absence of weight on animal when passenger is in vehicle. It is entirely new and the only vehicle ever produced that fully meets the requirements of a physician in every respect.

The low hang of the body renders it easy of INGRESS and EGRESS, thus overcoming one of the most monotonous parts of the physicians' practice. In the upholstery of the seat and back, it affords the greatest luxury. Has regular Physician's Close Top, with large side lights, stationary storm apron on dash, large drawer under seat for instruments or medicine case, and is furnished with large serviceable French Cylinder, oil burning reflector lamps when desired.



Most Perfect, Stylish, and Easiest Riding Physicians' Cart Ever Built.

Built with pole for team, instead of shafts when desired, as in the absence of weight on animal, it is the only two wheeler to which a pole can be successfully used. Making it of greater ease and of lighter draught for animal to handle, than any two or four wheeled vehicle ever produced.

Send for Illustrated Catalogue and Price List. Correspondence Solicited.

Clinical Lecture.

ANGINA PECTORIS. MIXED PNEUMONIA COMPLICATING A DOUBLE HEART LESION.

TRAUMATIC CERVICAL MENINGITIS. TYPHOID FEVER COMPLICATED WITH CROUPOUS PNEUMONIA. RESULT OF HYDRO-THERAPEUTICS,[1]

BY SOLOMON SOLIS-COHEN, M.D.,

Professor of Clinical Medicine and Applied Therapeutics in the Philadelphia Polyclinic, Visiting Physician to the Philadelphia Hospital.

GENTLEMEN: I show you to-day a number of convalescents to demonstrate the results of treatment. First, we have here a case which some of you may remember as having been shown to the class in the early portion of the winter. It is a case of angina pectoris, the man having suffered from very severe, very prolonged and frequently repeated attacks of cardiac pain, associated with severe dyspnœa, and sometimes with syncope. The peculiar interest of the case lay in the large doses of nitro-glycerine we were compelled to administer. We failed to get the desired effect from its internal use, and so we resorted to hypodermic injections, giving from ten to fifteen minims of the centesimal, or 1 per cent. solution in alcohol, at a dose. In addition he was, later, given the nitrite of sodium internally, in doses eventually increased to five grains, three times a day. Thus at one time he was taking forty minims of a 1 per cent. solution of nitro-glycerine—very nearly one-half minim of pure nitro-glycerine hypodermically — and fifteen grains of sodium nitrite by the stomach, in the twenty-four hours. Even this proved inefficient at one time, and we supplemented it by morphine with atropine hypodermically. Thus far we have had very good results, since he has had no attack since April 16, about eight weeks. As a matter of course his stomach has not been allowed to be overfilled, and his bowels have been kept open. After his attacks were somewhat controlled, and we had therefore considerably diminished the quantity of medicaments administered, we noticed a hysterical element in the case, in addition to the organic trouble. This led us to give hypodermic injections of aqua destillata, and internally, pills of althea, the patient remaining under the impression that the nitrites were still being used. The hypodermic injections have now been discontinued and he is getting only the pills; as no further attack has been noticed in four weeks of this treatment, it may serve to illustrate the triumph of mind over matter. It must however be distinctly borne in mind that in the beginning, psychical influences would have been totally unavailing, to control even the morbid fear of attacks which aggravated their severity and perhaps increased their frequency. The decided physical effect produced by the drugs employed was the curative agency; the treatment by suggestion, merely served to prolong its good results, and overcome the element of fear still persisting.

This case was also before the class early in the course. The man, at that time, was recovering from an attack of influenza manifesting itself as a mixed pneumonia, neither exclusively croupous nor exclusively catarrhal, but sharing the clinical characteristics of both. Recovery has taken place notwithstanding very serious heart lesions of long duration, ten years or more; mitral incompetence and aortic stenosis, with some accompanying aortic incompetence. You may remember that during the acute attack his respirations had been at times greater in number than his pulse-beats. When the respirations reached sixty per minute, and often when they were not more than fifty, they exceeded his pulse. The interest in the case was chiefly therapeutic; namely: the absence in the treatment of all antipyretic drugs —which would certainly have caused his heart to cease beating forever—and the employment of atropine and strychnine in combination for the heart difficulty, instead of drugs like digitalis or strophanthus, which might, perhaps, have been deemed at first sight to be indicated. The nitrites were also employed from time to time, with advantage. The patient has gained in weight and strength since convalescence set in, and can now walk about quite comfortably. His shortness of breath is not marked, except after climbing two flights of stairs; his pulse to-day is 72, and respirations 20. His heart lesion remains, but we are fairly compensating it by the use of drugs. He is advised to keep comparatively quiet, but is allowed to go about a little for fresh air.

At the beginning of March this next patient, while

[1] Delivered at the Philadelphia Hospital.

intoxicated, fell from his chair in such a way as to bend his head under his chest. He remained unconscious for about an hour, but on recovering seemed perfectly well, and for two days attended to his work. On the afternoon of the second day he experienced pain in the back of his neck, dull and throbbing in character. Later, this pain extended into the shoulder upon the line of the spine of the scapula, and in the infra-clavicular region. He now took to his bed, where he remained for four weeks. His pain was now better, now worse, and at times he was unable to raise his head from his pillow. He then was admitted to the hospital. There was no swelling of the joints, and no pain in his limbs. He was unable to lie upon his left side because of the pain in his left shoulder, and on sitting up his head inclined markedly downward, forward, and to the right. There was pain on pressure over the fourth, fifth and sixth cervical vertebræ; especially marked in the interval between the fifth and sixth spinous processes. He could not lift his head, nor move it from side to side, and could nod but to a very limited degree. There was no spasmodic contraction of muscles however, as in ordinary torticollis. He could not abduct or lift the arm, though the fore-arm moved freely. Here we have a condition often erroneously called rheumatism; pain in the shoulder and head, stiffness of the neck, and inability to raise the head and arm. There is no heart lesion, no fever, and the trouble can be traced to a fall while in a state of intoxication, although immediately after the fall he was able to attend to his work. The conclusion was reached that we had to deal with a slow superficial meningitis, confined to a restricted area in the neck. Possibly there had been some involvement of the nerve roots, which would account for the pain in his shoulder and hand, and the slight paretic element present. Mild cases of this nature do not come to autopsy, so that an element of doubt is involved in the diagnosis; but to my mind the explanation given is the most probable.

The treatment has consisted in blistering six inches over the cervical spine and along the crest of the shoulder. He has been given increasing doses of potassium iodide, in saturated solution so that one minim of the solution contains nearly one grain of the salt. We began with fifteen minims three times a day, and ran up to thirty minims, stopping there because we had produced iodism. The improvement has been very rapid; he now has no pain and can move his head freely in all directions, and lift the arm at the shoulder. The bowels have been kept open by sulphate of magnesium, and all the secretions regulated.

Here is a patient who is convalescing from typhoid fever. He is aged eighteen years. He came into the house on the first of May, with a temperature at 3 P. M., of 102.6°; at 7.15 P. M., the same day, it had risen to 105.6°. The rose spots and the other symptoms indicated that the patient was in the second week of his fever, probably at the ninth or tenth day. He had not previously been treated, and had been walking about. The resident physician, Dr. Sothern, who saw the patient on admission, following the standing instructions in my ward, immediately instituted the cold water treatment, and at 8.15 P. M., after cold sponging, the temperature had fallen to 102.2°. No antipyrin, antifebrin, or other dangerous explosive had been administered. I would have preferred cold bathing to sponging, but unfortunately the former is not as yet practicable in these wards. We begin sponging with tepid water, and during fifteen minutes gradually reduce the temperature to about 50° F. A little alcohol is added to promote evaporation. As a matter of course the patient's temperature rose again, and at 10 P. M. it was 104.2°. Again he was sponged, and it fell to 101.8°, and so it has run throughout the course of the disease; the period of comparatively low temperature, however, gradually lengthening, while it has not risen above 103.5° since the first day after admission. The difference between the morning and evening temperature, usually so marked in enteric fever, is almost obliterated here by the cold water treatment, as is shown by this chart.

An interesting feature of this case is that this man had pneumonia with his typhoid fever, a rare complication. A great portion of the so-called typhoid pneumonias are pneumonias of a low type, having no enteric complications whatever; others are simply hypostatic congestions associated with bronchial catarrh in cases of enteric fever—still others are cases of mixed bronchial and intestinal influenza or catarrhal fever—but this man had, so far as physical diagnosis could inform us—and happily the confirmation by section is lacking—a genuine lobar pneumonia of the right base, complicating his typhoid fever. The treatment, in addition to cold sponging and the internal administration of salol, five grains four times daily, as an intestinal disinfectant, with calomel as required, to keep the bowel clean; was an ammonium mixture for his pneumonia, and counter-irritation, in the form of turpentine stupes following a mustard plaster, over the base of the right lung. Under this treatment he has recovered. I do not say he was cured, you will notice. The tendency of this disease is to recovery, barring accident, and all the physican can do is to bar the accident. This, I think, we have here accomplished. His diet, of course, was strictly regulated. The formula of the ammonium mixture which I prefer in cases like this, is as follows:

℞.—Ammonii salicylat.,
Ammonii carb . . . . . āā gr. v.
Spt. ætheris nit. . . . . ♏xv.
Ext. cocæ fld.,
Glycerini . . . . . āā f℥j.
Liq. ammonii acetat. . . . q. s. ad f℥ss.

The erythroxylon coca is used to disguise the taste of the ammonium salts, and to act as a cardiac stimulant and tonic; the "nitre" is a mild diuretic, diaphoretic, and cardiac stimulant. A small quantity usually increases the efficacy of more active preparations of a similar class. This dose is given every two, three, or four hours, according to indications. The dose of the ammonium salts may be altered according to circumstances. I do not think that the value of the salicylic salt is appreciated generally to its full deserts. The amount of whiskey given was not very great. Towards the close of typhoid fever is the time to increase the amount of alcohol. We began with three ounces per diem, and increased to six ounces per diem towards the close. He is now on the compound tincture of cinchona. At one time in the disease we gave turpentine to meet special indications. When the tongue is dry and glazed and brown, and there is marked tympany or a tendency to heart failure or intestinal hemorrhage, turpentine is beneficial. It may be given in emulsion, five or ten minims every two to four hours as required. Sometimes it may have to be intermitted or even withdrawn altogether because of suppression of urine, strangury or even hæmaturia. I have seen similar ill-effects from terebene and from terpine hydrate. In what is technically known as the "cold water" or "Brand" treatment of enteric fever, no medicine is given. Systematic cold bathing is faithfully carried out. It is the best method of treatment of which I have knowledge.

Original Articles.

A CLINICAL STUDY OF SULPHO-CARBOLATE OF ZINC.[1]

By WILLIAM BLAIR STEWART, A.M., M.D.

FOR many years diseases of the gastro-intestinal canal, as well as those of other organs, were treated empirically; but, at the present day, with our knowledge of bacteria as an etiological factor, we are enabled to strike directly at the seat of the trouble, in many cases, and treat on scientific principles. It is not my intention, in this article, to review the whole field of antiseptics, nor to enter into a discussion of the intestinal antiseptics in general, but I wish to direct the attention of the profession to some of the results that have been obtained from the use of sulpho-carbolate of zinc. My attention was first directed to this drug in the fall of 1887, and, since that time, I have had an opportunity of studying its action in the treatment of affections of the gastro-intestinal tract and other organs.

WHAT THEN IS SULPHO-CARBOLATE OF ZINC?

Sulpho-carbolate of zinc is a new unofficial salt, prepared by the action of a concentracted solution of barium sulpho-carbolate on zinc carbonate, by which sulpho-carbolate of zinc is formed.—Remington.

Properties.—It is a crystalline, transparent salt which is permanent in air. It is neutral in reaction, and has no smell. It has a taste somewhat bitter and cooling as well as astringent. It is soluble in water and alcohol and gives a perfectly clear solution. When heated moderately, the water of crystallization is thrown off and a white powder remains. When a higher degree of heat is applied, inflammable fumes are given off, which emit the odor of carbolic acid, and a white tasteless residue remains. With this brief reference to the drug, its preparation and properties, I will pass to a consideration of its therapeutic effects without entering into further details as to its chemical and pharmaceutical history.

Under the head of summer diarrhœa we find a class of maladies that often prove to be intractible and fatal under the ordinary forms of treatment, but now much can be done to effect speedy recoveries in many cases, and to diminish the mortality by the intelligent use of this valuable remedy—sulpho-carbolate of zinc.

Investigation has shown that most forms of summer diarrhœa are due to the irritation caused in the alimentary tract by certain disease germs, and their ptomaines which are developed in undigested and fermenting food. Bearing this in mind, many cases can frequently be relieved by a dose of aromatic syrup of rhubarb, or a dose of oil to stimulate the intestines to throw off the offending material. The main principle to be considered is that of *elimination*, for, so long as the poisonous matter remains in the bowels, we have a focus from which the trouble will spread, and no amount of antiseptic medicine will render it inert. However, it is not to these mild cases that I refer, but to those in which the ordinary cathartic will not bring relief.

Given, a typical case in which a child is vomiting; has pain in the stomach and bowels, with a high fever; what is the condition, and what are the indications for treatment? The whole trouble is traceable directly to the intestinal canal which is swarming with microörganisms and, what is worse, their ptomaines. These germs, by their action, are a source of irritation to the intestinal mucous membrane, and also cause a fermentation and decomposition of the food or fluids which, with the ptomaines and secretions, cause the fetid discharge. What then happens? The absorbents take up the septic matter and ptomaines and throw it into the circulation, and, by this, we can account for the fever and constitutional symptoms.

Purgation has been sufficiently free, and the child is so sick that nothing in the nature of a strong dose could be retained on the stomach and, again, it is necessary to stop the violent drain on the system as soon as possible. The line of treatment is now evident, and what is wanted is a remedy that will be carried to the intestinal canal and kill the germs, neutralize the ptomaines and stop fermentation. The cause once removed, the constitutional symptoms will subside. It is almost impossible to find a remedy that can be administered in quantities sufficient to accomplish this result without endangering the life of the patient, but there is one remedy that can be given in efficacious doses, and that is the sulpho-carbolate of zinc.[1] To a child, two years old, I would give ℞.—Zinc sulpho-carbolate, gr. 1-4; bismuth subnit., gr. 1, every two hours, increasing the sulpho-carbolate at every dose, if necessary, until two grains would be given at one dose. As the symptoms subside, lengthen the interval for administering the medicine. If the first dose is vomited, persist every fifteen minutes or longer until a powder can be retained. If administered in this way, the first change noticed is in the vomiting, which is almost immediately checked after the first dose. The fermentation of the food is checked and the pain subsides as a consequence. After a few doses have been taken the fever and constitutional symptoms subside, the stools lose their odor, become less frequent and assume a normal condition. Sometimes the diarrhœa and fever do not subside under this treatment because the ptomaines and germs are active in the lower bowel and cannot be reached by the mouth. In this case, make a solution of five or ten grains of the sulpho-carbolate to the pint of hot water, and use freely at regular intervals as an injection. Do not be afraid to fill the bowel full of the solution or you may not obtain the desired result. In addition to this treatment, as in treatment of all other diseases, it is necessary to regulate hygiene and diet, and meet the other complications, as they arise, with the appropriate remedies. Good nursing is half of the battle.

There are those who advocate the use of other remedies, and, in some cases, undoubtedly obtain good results; but, many times, when we come to consider the rationale of their treatment we meet with great obstacles. Undoubtedly good results have been obtained from the use of other combinations, and I have found it so in my own hands, but it is well to have a variety of remedies from which to select, and this one is worthy of a high place in the catalogue.

A germ is a germ, whether in a man or a child, and it will take as much medicine to kill it in the one as in the other, except that we find a proportionately larger surface of mucous membrane in the adult. Bichloride of mercury has its advocates; but it is found that a dose sufficient to render the intestinal canal aseptic would kill or seriously endanger the

[1] Read before the Atlantic County, New Jersey, Medical Society, September 3, 1890.

[1] I do not wish to be quoted as saying that the intestinal canal can be rendered entirely aseptic, but the sulpho-carbolate will come as near producing this condition as any other remedy.

life of an adult. Again, it forms albumenate of mercury, which is not antiseptic. How much less would this remedy be applicable in children? "Hydronaphthol has been used by an English physician as an intestinal antiseptic; but a limit of tolerance was reached before it rendered the intestines aseptic." (Waugh). Others claim that this salt is innocuous. (*Therap. Gazette*, Aug. 15, 1890, p. 544). It, as well as beta-naphthol, is not efficient or suitable in children. Salicylic acid and the salicylates are too irritant to the mucous membrane of the bowels, and are unpleasant remedies in children. Salol is a valuable remedy, and most excellent results are reported from its use.

As to the merits of the sulpho-carbolate of zinc: It has been given in fifteen-grain doses to an adult without causing any symptoms of irritation or unpleasantness, and one case is quoted by Dr. W. F. Waugh, of Philadelphia, where sixty grains in one day gave no unpleasant or toxic symptoms. Why, then, is the zinc salt preferable to the officinal sulpho-carbolate of soda or sulpho-carbolic acid? Phillips, in his work on Materia Medica, in speaking of the sulpho-carbolates, says: "The administration of these salts, however, offers an indirect method of giving carbolic acid. . . . These alkaline compounds, however, have less local irritant action, and up to the present time have not caused poisonous symptoms." (Page 866). Dr. Cerna (*Medical Times*, Vol. X, p. 209) sums up his article on the sulpho-carbolates as follows: "1. The sulpho-carbolates possess toxical properties for cold-blooded animals. 2. In warm-blooded animals these salts are innocuous." The zinc salt is more or less astringent, and has a better action on the mucous membrane of the bowel, and is a nerve stimulant, while the sodium lacks this virtue. The zinc salt also acts more like small doses of arsenic and copper, the virtues of which have been well established.

Again, Potter (Therapeutics, page 396) says of the zinc salts: "They manifest a much less tendency to accumulate in the system than the other metallic salts, and are excreted much more rapidly. Elimination takes place chiefly by the liver and intestinal glands." Zinc acts also as a nerve tonic. The general supposition was that the zinc sulpho-carbolate was not fit for internal administration, and for this reason it has been slighted by our authorities in its consideration; little space and attention being given to it. The pure sulpho-carbolic acid could not be given on account of its obnoxious smell and taste, as the little ones would rebel against it.

In the administration of germicides, the first principle to be observed is to give enough to destroy the germ without endangering the life of your patient. During the past two summers it has been my privilege to treat a great number of cases of summer diarrhœa and cholera infantum without the loss of one case, and my mainstay has been the sulpho-carbolate of zinc. I will mention two cases from my clinical record.

CASE I.—Martha J., aged ten months, was seized with violent vomiting and greenish diarrhœa. Nothing would remain on her stomach, and she was unable to retain any nourishment. There was some fever; pulse was high, and the child was very restless. It was bottle-fed. The above prescription was ordered and instructions in regard to diet were given.

℞.—Zinci sulpho-carb..... gr. 2½
Lacto-peptine..... gr. 12
Bismuth subnit..... gr. 18

M. Ft. chart No. 12.

Sig.—One every two hours until relieved; then increase the interval, and give as necessary to control the bowels.

From the first dose the child began to improve, and in two days had completely recovered. The zinc salt acted as an antiseptic, antispasmodic, and astringent; the pepsin as a digestant, and the bismuth as a sedative and astringent. During the remainder of the summer the child had several severe attacks, but was promptly relieved by the same treatment.

CASE II.—Mr. James G., a laborer, was seized with violent vomiting, cramps and fetid diarrhœa. I found him in bed, very weak, nervous, and restless, and still inclined to vomit everything he attempted to swallow. He was given a powder containing two grains of the sulpho-carbolate and two grains of bismuth, to be repeated every two hours. He improved from the first dose. Nausea ceased, pains disappeared, and after the fourth or fifth powder the diarrhœa ceased. He slept soundly all that night, and was put on a tonic, and in a few days was able to resume his duties in full.

I could cite many cases of similar character that have come under my care, and in every case the same uniform good results have been obtained.

I wish next to call your attention to another property of this agent, viz., its employment in combination with purgatives and other irritants (local) of the alimentary canal for its sedative effects. The griping produced by cathartics may often be measurably overcome by combination with the sulpho-carbolate of zinc. I have found it of especial value where a slight astringent action is desired in connection with cathartics, to prevent too free and active purgation. Ordinarily it acts very nicely in this combination, and is worthy of your attention. It answers very nicely to take the place of the opiates which are so frequently used with purgatives. A short letter received from Dr. T. S. Blair, of Chambersburg, Pa., will give a good idea of its use in this connection. He writes:

"In reference to the use of sulpho-carbolate of zinc, I would say that, aside from its usual purposes, I have employed it in acute summer diarrhœa and as a corrigent in various cathartic preparations in general use. For the common bilious attacks of adults I usually write as follows:

℞.—Hydg. chl. mit..... gr. 4
Podophyllin..... gr. ½
Zinci sulpho-carb..... gr. 1½

M. et ft. chart No. 3.

Sig.—One at six P. M., one on retiring, and, if necessary, the third powder in the morning.

"The above is very efficient in severe cases, and the zinc prevents largely the griping and nausea produced by the podophyllin. Owing to its astringent and antiseptic qualities, the salt is especially applicable in summer diarrhœa, and I usually exhibit it in a combination, as follows:

℞.—Hydg. chl. mit..... gr. 5
Pulv. rhei..... gr. 15
Zinci sulpho-carb..... gr. 3

M. et ft. chart No. 3.

Sig.—Take, in rice-paper wafer, same as in last ℞.

"This is for an adult. I find this mixture an admirable purge for general purposes, and have particularly noted its power of rapidly reducing fever due to indigestion or congestion of the bowels. I have used it a score of times in cases where a good purge was necessary and the patient could not leave his business. It produces the minimum of nausea and yet proper efficiency. In many cases I reduce

the quantity of Hg. For children I usually prescribe the proper quantity of blue mass or mercury and chalk, in place of calomel; but a slight increase over the ordinary dose is required, owing to the astringent quality of the sulpho-carbolate." * * * *

Dr. Boardman Reed, of Atlantic City, N. J., kindly contributes a few lines in relation to his experience in the use of this remedy: "A delicate child was brought here from a Western city in the early part of the present summer, suffering with chronic intestinal catarrh, which seemed to be a sequela of la grippe. It was a baby of about a year old, and though it was having only three or four slimy stools a day, was already considerably emaciated. After trials with various other remedies, the child was placed on the sulpho-carbolate of zinc, one-quarter-grain doses, combined with one grain of lacto-peptine after each feeding. Half a teaspoonful of castor oil was administered once in two or three days, to clear out the bowels, and cod-liver oil was rubbed into the skin every day. The result was quite satisfactory. The stools gradually became fewer in number and of better quality. In the course of a month after this treatment was instituted, the mucus had almost entirely disappeared from the stools, and the latter were beginning to be formed.

"I have used this drug in numerous other less stubborn cases of intestinal flux, and nearly always with satisfactory results. It combines the properties of a mild, but apparently active germicide with those of an efficient astringent."

All modern investigation and research point to the fact that typhoid fever is due to a distinct germ, which finds its habitation in the intestinal canal—confining its attacks to the mesenteric glands and the patches of Peyer. Prior to the discovery of the bacterial origin of this disease treatment was symptomatic, and the best and most successful remedies, that were then used empirically, were those that we now know to act as germicides. In addition to the actual use of antiseptics, we must also bear in mind the fact that there are remedies that can arm the body against the invasion of disease germs by rendering the body an unsuitable soil for their growth and development.

Without entering into a discussion of the merits and demerits of the old and well-tried methods of treating typhoid, I wish to present the clinical results of the use of the sulpho carbolate of zinc in this disease. I am one of the firm believers that typhoid, in its first stages, is a localized disease manifested by constitutional symptoms due to the presence of micro-örganisms that are inhaled or ingested with food or drink. These germs flourish and grow, and, at first, are confined to the stomach, when in an unhealthy condition, and upper bowel; later the lower bowels are attacked, and so great becomes the action of these germs that the system can no longer withstand them, and, as a consequence, their ptomaines are absorbed; great depression supervenes and frequently death. With this brief review of the etiology of typhoid, the rationale of the use of the sulpho-carbolate becomes apparent, as in the cases of diarrhœa.

I have seen many cases that presented the typical symptoms of incipient typhoid, which were aborted by the administration of two-grain doses of the sulpho-carbolate of zinc every three or four hours, for the first few doses, and then lengthening the interval. Dr. W. F. Waugh reported thirty-four cases of typhoid fever, which he treated with the sulpho-carbolate of zinc, and did not have a case in which perforation, hemorrhage or grave nervous symptoms ensued during the use of this drug, as was the case with other remedies. Every case recovered. He gave three grains every two or three hours in a little water and noted that the stools soon became normal and lost their odor; diarrhœa was checked; tympanites subsided; the stomach became quiet; the temperature became one or one and one-half degrees lower, and the delirium and stupor subsided. No antipyretics were needed; but, in some few cases, where the heart was weak, stimulants were necessary. Bovinine, thickened with the white of an egg, constituted the best diet.

The great secret in the use of this, as well as all other antiseptic remedies, is to begin its use early in the course of the disease, and to use it persistently and in doses sufficient to render the alimentary tract as nearly aseptic as possible.

I have received a very interesting letter from Dr. W. G. Stewart in relation to the use of this drug, and it is worthy of a passing glance. It reads as follows:

"In December, 1888 and 1889, I treated seven cases of typhoid fever in one family, all well-marked and nicely defined cases of that disease. The general and leading symptoms were confined principally to the bowels—most of the cases having swollen and tender abdomens, with some hemorrhage. Temperature ranged from normal to 105° F. I treated these cases with the sulpho-carbolate of zinc, pepsin and opium. I gave the zinc in one-half to three-grain doses every two, three, or four hours, as indicated and according to age. Every one of the family recovered promptly, with no unpleasant sequela. The zinc salt is an invaluable remedy in all well-defined cases of typhoid fever, and should be given in all stages of the disease for its antiseptic properties, and as a guard against hemorrhage.

"In 1889, I treated about seventy cases of infantile diarrhœa and cholera infantum with the sulpho-carbolate of zinc, pepsin, bismuth and opium. The zinc was given in one-quarter to one grain doses every three or four hours, and with a uniform good result in every case.

"In August, 1889, a man of about forty-five years, called to see me who was suffering with the regular 'bloody flux.' I gave him three grains of the sulpho-carbolate of zinc, with one-half grain of opium every three hours. In twenty-four hours he was entirely relieved and resumed his regular duties on his farm.

"In January, 1890, was called to see a man of seventy-two, with hemorrhage from the stomach, vomiting blood in large quantities, and was in a very weak and reduced condition. I at once gave him five grains of the sulpho-carbolate of zinc in a wine-glass full of water, which stopped the vomiting and all hemorrhage. The zinc was continued in three-grain doses every four hours, and my patient has now entirely recovered, and has had no symptoms of any return of the hemorrhage.

"So far, in the summer of 1890, I have used this salt in about forty-five cases of diarrhœa and cholera infantum, and have obtained the same results as before. I am fully satisfied that in the sulpho-carbolate of zinc we have a valuable remedy; one on which we can rely with confidence. In all, I have treated over one-hundred and fifty cases with this drug, and in *no case have I regretted the selection of the remedy.*"

Dr. George Grove, of Big Spring, Pa., a physician who has practised medicine for more than fifty years, writes that: "From the first dose of sulpho-carbolate of zinc, with bismuth and opium combined, in two cases of typhoid fever in the third week, the irritability of the stomach was relieved, and the stools lost

their fetid odor in twenty-four hours' time. I then gave cinchonidia every four hours, and in eleven days my cases needed no more attendance. These were cases of typhoid abdominalis. Regarding the diarrhœa of children, I think it is the *rem tendere* (or the thing intended.)"

Every drug will be used in some cases where it will not accomplish the desired result, and so with this one. A case just now comes to my mind where a physician used the sulpho-carbolate of zinc in a bad case of typhoid fever. The case was that of a young man, aged twenty-two years. He had a high temperature, and blood-stained stools. The sulpho-carbolate was given; but, in spite of all treatment, perforation and profuse hemorrhage supervened, and the patient died. Now it is altogether possible that the sulpho-carbolate was not used early enough in this case, and not in sufficient doses to accomplish the desired result. When typhoid, like all other diseases, has assumed a malignant form, in which the blood is disintegrated and the whole system depressed, it cannot be expected that this, or any other remedy, can repair the damage which has been done; death alone can end the scene.

I am unable to learn of any authentic cases of Asiatic cholera or yellow fever in which this remedy has been given a fair test; but I believe that it is well worth a trial in these affections. Owing to its astringent, anti-spasmodic and antiseptic properties, it seems to me that if the remedy were given boldly and in large doses (five to fifteen grains) every few hours, at the outset of these troubles, the disease might be checked, or greatly mitigated in its severity. This drug does not possess the same astringency as that found in the sulphate of zinc, but it will act much better locally in many cases; and, having in addition the antiseptic properities, is preferable.

By using from two to four grains of the salt to the ounce of water we have a very good injection for gonorrhœa, leucorrhœa, or gleet. In an article written by Dr. J. William White for the *Medical News* (June 14, 1890), he refers to the use of a combination of corrosive sublimate and boric acid in the treatment of recent anterior urethritis. He then says: "I felt, however, the additional need of an astringent, and for a long time employed the sulphate of zinc, for which I have recently substituted the sulpho-carbolate (two to ten grains to the ounce of the mixture). By using a ten to fifteen per cent. solution of peroxide of hydrogen as a menstruum, I then found that I had a formula which, both clinically and experimentally, showed excellent antiseptic qualities. In exceptional cases of profuse catarrhal secretion the addition of bismuth salicylate was also of advantage."

It is also very valuable as a lotion in discharging wounds and mucus surfaces. It has been used in balanitis with success. In the London Throat Hospital ("Wood's Medical Formulary," page 382) it is "used tropically as a stimulant and antiseptic. R.—Zinci sulpho-carbolate, gr. 5; distilled water, ℥i. M.—Used by means of spray apparatus. Used in secondary syphilis of the larynx and pharynx."

Phillips (Therapeutics, page 866) speaks of its use in scarlet fever. "In twenty-nine cases, some extremely severe with suppression of rash and convulsions, all recovered except one (a syphilitic baby). Convalescence was most complete in seven to fourteen days. No topical treatment was practised, and Dr. Sansom fairly concludes that by the sulpho-carbolates the duration of the attack was shortened, the pyrexia lessened, and the throat symptoms especially benefited." Sulpho-carbolate of zinc is also used with benefit, in the vomiting of pregnancy, with small doses of calomel.

Thus far, in my consideration of the sulpho-carbolate of zinc, it has been used in combination with bismuth, and the question that naturally presents itself is: Whether the action is obtained from the bismuth or the sulpho-carbolate? I have used it alone in treating diarrhœa, and have obtained very satisfactory results. It has been used by other practitioners, and at present some of our leading pharmacists are putting up the drug in the form of a tablet containg from one-half to two grains. It has been found, by my experience at least, that the sulpho-carbolate will act better in bowel complaints if combined with bismuth or pepsin. Any one of these drugs will act nicely alone in many cases, but, by their combination, we have a much more reliable and active prescription.

This constitutes the main portion of the literature now extant in relation to the use of sulpho-carbolate of zinc, and, in summing up the whole subject, entirely from a clinical standpoint—not a theoretical one—I am more than ever convinced of its usefulness and value in summer complaints and septic fevers.

I am very forcibly impressed with the saying, "Never be the first by whom the new is tried, nor yet the last the old to lay aside." It is the duty of every practitioner in medicine to seek and search for those remedies that will afford prompt and permanent relief, all "pathy" being laid aside; but it is not well to take up every new remedy that may be recommended by this, that, and the other man, unless a scientific and practical reason can be given for its use. *Clinical experience* in the use of drugs is the best way to decide their usefulness, and, no matter how plausible the theory may be, we must be guided by it in their use. The medicinal value of the sulpho-carbolate of zinc and the sulpho-carbolates has been sufficiently demonstrated at the bed-side and in the clinics to firmly ingraft them among the stable remedies at the hand of every practitioner.

FOOD AND TUBERCLE.[1]

BY EPHRAIM CUTTER, M.D., LL.D., A.M.,

Hon. F. S. Sc., London, and President American branch of same. Author of Boylston Prize Essay, 1857, on Under What Circumstances do the Usual Signs Furnished by Auscultation and Percussion Prove Fallacious. Inventor of several forms of the Clinical Microscope; first to Photograph the Morphologies of Diseased and Healthy Blood, 1876, with Tolles' one-fiftieth and seventy-fifth-inch objectives, etc., etc.

INTRODUCTION.

THE great aim of the physician should be to cure, if possible. Efforts, however praiseworthy, famous, and popular, that stop short of this, are not rounded out to full completeness and perfection. Those who advance our knowledge of causes of disease are entitled to honor and remembrance, but those who advance the cure are entitled to at least the same credit, if not more. If any one knows, or thinks he knows, the way to cure a disease deemed

[1] Being part of the discussion on tubercle, pathogeny and pathological anatomy, section of pathology—Tenth International Medical Congress.

incurable, it is his duty to make known the facts, and give opinions based on those facts; and, so long as he observes the rules of good breeding, he is entitled to a respectful hearing.

Controversy must be waged on *facts*, not individuals. Science is based on facts. Uniformity of opinion is impossible. Witness the want of agreement as to ether and chloroform, though used freely by all schools of medicine since their discovery.

The medical world holds a congress. Its members are expected to contribute to the common stock of knowledge, as when a congregation takes up a collection for a benevolent object. Each one gives as he has means, gold, silver, or nickel. He gives of his own. Now here, in place of money, we give ideas and histories. So I give my nickels. If, by this act, any one is treated better in consumption the contributor shall be satisfied.

CONSUMPTION IS CURABLE.

Fact 1. Docent Dr. Heitler, of the Pathological Institute of Vienna, in 1880 published an account of his having met with about sixteen thousand autopsies of persons of all ages, sex and condition, dying from all causes, in which he noted that nearly five per cent. had had consumption of the lungs which had got well, or the case had died from consumption developed in other parts of the body.

Remarks.—If this statement is incorrect, please correct it.

Fact 2. In a work on disease of the chest, published by the late Dr. W. W. Gerhard, of Philadelphia, about 1850, he speaks of the curability of consumption by Red Sulphur Springs Water.

Fact 3. About 1860 a maternal uncle of mine died, aged 66, of Bright's disease. At the autopsy were found five stellate cicatrices in the upper lobe of the left lung of old cavities. In his youth he had cough, hemoptyses, lost flesh and strength, and was said to have been consumptive. I think it was so.

Fact 4. Dr. H. I. Bowditch, son of the eminent mathematician, Nathaniel Bowditch, of Boston, well known as the author of "Bowditch's Navigator," in June, 1889, called me to his house to hear him read an account of his father's case of consumption, cured by taking a six-weeks' carriage journey. This report has been read before the American Climatological Association, and published.

Fact 5. In the appendix of this paper is published one hundred cases of consumption; twenty-one non-arrests, thirty-nine temporary arrests, and forty permanent arrests of the disease.

Remarks.—These facts convince me, and for one I cannot, in face of them, tell my patients in consumption their cases are absolutely hopeless; if I did so, these facts would contradict me.

WHAT FOOD HAS TO DO WITH CONSUMPTION.

1. The one hundred cases alluded to were all treated on food basis. Without the diet they could not have had the history reported.

2. Food causes tubercle.

(*a*) In 1858 (see "The Relation of Alimentation and Disease," by J. H. Salisbury, M.D., LL.D.: J. H. Vail, New York, publisher), six hundred swine were fed on good sweet maize. None died.

(*b*) Close to them one thousand and twenty-six hogs were fed on sour swill from a distillery. In the course of eight weeks two hundred and fifty-six died. Of these, one hundred and four were autopsied, and seventy-nine were found to have tubercle in lungs.

Remarks.—Some would say these facts are not so. Tubercle was not found. Other scientists do not report such results. All right. Just so the results of the East India commission as to ether and chloroform have been rebutted by the results of the late work of Philadelphia experts. Again, it makes a ground of difference as to what one looks for in an examination. Before our late war, 1861, emery came only from the island of Naxos, I am told. For a long time mineralogists knew of a source of a peculiar form of magnetic iron ore near Lee, Mass. After our war began, and there was a great demand for emery, some practical expert examined this magnetic iron ore locality with a view *to find* emery of better quality than the Naxos, and the discovery of it was of the greatest importance to America. So it seems the savans did not look at the subject in the right light. Would that the profession would repeat these experiments on swine, with a view to the production of tubercle, and report their results. They might not agree any better than the etherists or chloroformists, but some good would come from the work. To my mind these experiments and cases are enough to satisfy me of the causal relations of *food* in acetic acid fermentation to cause tubercle.

BUT WHAT WILL YOU DO WITH THE BACILLUS OF KOCH?

Reply.—It is found in sour fermenting food, and I photographed it in 1876 with the one-fiftieth-inch objective of Tolles. I can throw this photograph on the screen. The illustrations that accompany this paper are but a few photogravures of microphotographs that I have made; their number runs far beyond one hundred. I have the text of an essay on the pretubercular state, to be illustrated by a large number of microphotographs. This work will be published whenever the profession demands it.

This bacillus, from thirty to forty years, has been recognized by cryptogramic botanists. Some were of the opinion that it was present as an accident; others that it was a baby form of the acetic acid fermentation vegetation. It is to the honor of Dr. Koch to have settled this question as to being a baby form capable of reproduction in the baby stage. He, however, has not told us where it comes from, and has tied us up by coining bacteriology, which covers but a small portion of the micrological world. Again, his power to reproduce the disease by inoculations is due to the animalization of this innocent bacillus into a deadly power. I do not agree that tubercle is contagious. It certainly is not like small-pox, scarlet fever, diphtheria, or measles.

To my mind the whole life history of the bacillus includes the mycoderma aceti and saccharomyces cerevisiæ. To leave them out seems to me as reasonable as for me to give an account of the people I meet in this country by writing about the German babies and give no reference to the German boys and girls, men and women. Usually oak trees make more impression and do more good than acorns, though acorns should not be omitted in treating of oaks. But in this case the treatment is reversed in the writings of the bacteriological schools. Please remember this is writ—not controversially, but contributionally—as part and parcel of my own personal, practical experience, which, as a lesser light, only reflects the author quoted above. Those who will kindly peruse the appendix will see the details of treatment; those who consider these cases as idle tales—if they live long enough—may change their minds; but they cannot blame me for not having told what I knew in my time, and backing it up with original microphotography, which includes the work of the highest

power objectives ever used by man, to wit, the seventy-fifth- and the one-fiftieth-inch objectives of Tolles, and solar projection of living specimens, when circumstances permit.

ONE HUNDRED CASES.—RÉSUMÉ.

SERIES I.—*Non-arrests, 21 cases.*

(*a*) Cases that were not improved, 9.

(*b*) Cases that were on partial diet, or were too irresolute, or had bad surroundings—financial, climatic, etc., 12.

SERIES II.—*Partial arrests, 39 cases.*

(*a*) Cases that followed the treatment faithfully, 19.

(*b*) Cases that did not follow the treatment faithfully, 9.

(*c*) Cases that had bad surroundings, that died of pneumonia, etc., 11.

SERIES III.—*Permanent arrests, 40 cases.*

(*a*) Tuberculosis, 32 cases.

(*b*) Pretuberculosis, 8 cases.

NOTE.—The details of these one hundred cases have to be left out. They are made up of probably as severe a series of one hundred cases as is commonly found. Some of the permanent arrests are of twenty-five years' standing.

RATIONALE.

1. Tuberculosis is a systemic and not a local disease primarily.

2. Tuberculosis is a diseased condition or state due to the presence of a yeast in the blood with its fermentative products.

3. The yeast is introduced into the blood, through the alimentary canal, from starch and sugar in excess, and in a state of fermentation.

4. The physical micrographical conditions found in the blood of tubercular cases constitute the peculiar morphology so often alluded to. The main features are as follows:

(*a*) Spores of vinegar yeast.

(*b*) Spore collects.

(*c*) Fibrin filaments unusually large and prominent.

(*d*) Enlarged massal white corpuscles. This enlargement proceeding from the white corpuscles being unusually fertile niduses of the vegetation, called entophytal, similar examples of which abound in algæ.

(*e*) Deprivation of the red disks of their coating of neurine, thus rendering them sticky, adhesive, and singularly inclined to aggregate themselves in confused masses. At the same time they lose their color, their clean-cut outlines and are diminished in number, relatively and absolutely.

(*f*) Thrombi formed of the fibrin filaments, of the massal corpuscles, of the spore collects.

(*g*) All of the foregoing have been photographed with Tolles' objectives, from the one-fourth to his one-seventy-fifth.

5. The vegetations may exist in a latent state.

6. It may be transmitted from parent to child in the milk, but the greater point of interest is in the tuberculous diathesis, produced by the same feeding in families for generations.

7. The morphology of the blood is commonly present some time during one year before organic disease. In other words, there is a new physical sign of the pretubercular state. The senior writer has a monograph on that subject alone, illustrated with many microphotographs.

8. Food, then, is the agent of tremendous power that causes tuberculosis.

9. The treatment is based on the idea of removing the cause by ridding the blood of the presence of the yeast and its fermentative products by a process of starvation.

10. Tubercle is a secondary product—a result from embolism caused by the minute thrombi of fibrin filaments—of the massal corpuscles and of the spore collects, and also from mechanical and chemical effects of the embolism on the nutrition.

11. The breaking down of the tissues comes from a necrosis, caused by this overloading them with the products of fermentation.

12. The yeast is also found in the alimentary canal, on the skin, in the sputum, etc.

13. Flour has been raised into bread by the dejecta of third-stage consumptives.

14. The progress of the case is best watched and studied in the morphology of the blood. The spores are diminished, the filaments removed, the enlarged massal white corpuscles are reduced in size to normal proportions; the red discs acquire their normal color covering and clean-cut outlines; the fibrin filaments, are hardly visible. Thus the red discs dispose themselves in the normal manner, the more perfectly as the cure proceeds. Any deviation in the regimen is indicated by the increase of the abnormal morphological elements in the blood. As the blood improves, usually the general symptoms improve, pari passu. We have often witnessed, under treatment, the disappearance of rales of all kinds, night sweats, emaciation; the reduction of the heart to normal size and frequency of beats, simply because of taking away the load it had to carry, when the blood was filled with thrombi, and was ropy and sticky.

15. This diagnosis by blood examinations does not exclude ordinary physical explorations; it supplements them; we find that the ordinary idea of this diagnosis in the profession is that sanguinology is like urinology, and all that is necessary is to take specimens of blood, just as we do urine in other diseases, and base all our diagnosis of tuberculosis on such examinations. The very suggestion of this demonstrates how far the proposer is from having a true idea of the subject; the evidence must be collected with the least possible interval of time between the removal of the blood from its stream to the stage of the microscope; the capillary circulation is to be used; not the venous or the arterial; take blood from the radial or ulnar side of the forearm, by slight puncture with scarificator or scalpel; do not prick the finger; the student must study the morphology of the skin as well as that of the blood.

16. There are other diseases in which normal blood morphology is changed, to wit: Rheumatism, cystinæmia, syphilis, ague, etc.

17. This rationale explains the cough, where it is not due to local irritation in the air-passages, such as hyperæmiæ, ulcers, infiltrations, reflex irritations, to the presence of carbonic acid gas in excess; sometimes it is wonderful how diminishing the fermentation does away with the cough.

18. This rationale explains hemorrhages as the result of local action of vegetation on the glue tissues, the connective tissues being softened, disintegrated and broken down by the products of fermentative changes.

19. It explains the night sweats as due to the interstitial necrosis of tissues, thus throwing more work on the skin; hence the injunction to take good care of the skin and help the lungs while they are being healed.

20. The emaciation and loss of flesh and strength are only the results of the great tissue destruction going on.

21. The sputum must be studied for lung fibers, for the various crystals that are found in asthmatic conditions, and also the gravel, granular and encysted.

22. Old fashioned or fibrous consumption is due to holding of the yeast products in the stomach, to the gradual paralysis of the lungs by carbonic acid gas, with the consequent hyperplasia of the connective tissues, and to the deposit of gravel in this hyperplasia of the fibrous tissues; in this condition the blood morphology is not so much altered; the diagnosis must be made on more general grounds; the treatment is practically the same, however.

23. The condition of the liver and kidneys can be determined by watching the urine; it should be tested at least twice a week, and kept at a specific gravity of 1,015 to 1,020, free from bile, odor or deposit.

24. Physiologists say that man cannot live on beef alone; the chemist says (Gamgee) that beef contains all of the elements found in the tissues of the human body. We say, that in cases of consumption, Bright's disease, uterine fibroids, where the special case has indicated a rigid diet of beef, such a dietary has been ordered and some patients have lived on it for four years; thus the dictum of the physiologist is upset.

25. It has been sneeringly said that all that was needed if the ideas here given as to consumption are true, that a man prescribe beef and hot water; yet the contributor had his son study the general sciences four years, medicine four more, and special cases three more years, before he was willing to leave his practice in his care; the art of treating chronic diseases, even by positive food plans and judicious medication, is an extremely hard one to acquire.

26. Air is food. Yet consumptives have been cured in the rawest and dampest of climates, and so many times that we must go behind the old idea that climate was the only cause of consumption; granted that bad climate helps to cause the disease, and so also will worry, trouble, grief, assist towards death; the sending of patients away from home comforts to die elsewhere, is not the thing to be advised. If home comforts, good air and the proper food can be combined, by all means use them. This is written with the knowledge that pulmonary disease has been arrested by climate. But our aim is to cure the cases wherever they are, because many cannot afford to change their climate or to live the remainder of their lives in the Adirondacks or Colorado.

27. Remove from the atmosphere of the patients, all doubters, sneerers and those that argue, but never cure; agnostics and nihilists, not content with helping no one, they will endeavor to pull down your work.

More permanent arrests could have been secured of these one hundred cases if the patients had been left alone.

28. While encouraging the patient at all times and in all emergencies, give him to understand what he is fighting; that he must not waste his nerve forces by needless thought or worry, but to hold on persistently and wait for nature to do the work. Each case is a law unto itself. This can be seen by the study of the cases herein recorded. We are finite; death is certain. No man will ever cure one hundred per cent. of his cases—may we say of any disease?

29. If all will take hold firmly, at least fifty per cent. of tubercular cases can be cured, judging from our own clinical experience. Now that consumption is called a curable disease, the great load is lifted off, and much more will be accomplished.

30. All cases of pretuberculosis ought to be cured; because here is a condition where there has been no destruction of tissue. This is where the exception to Section 28 comes in, if the practitioners will diagnosticate the condition, treat scientifically, and the patient obey orders.

31. Of all physicians who say these plans are foolishness, and who treat their cases by morphine, maltine and whiskey, we ask for publications of cases and the percentage of cures.

32. The ability to diagnosticate pretuberculosis by blood examination, often negatively points out the seat of trouble to be in the heart or uterus, or perhaps some other organ; also, cases of uterine disease complicated with tuberculosis should not be allowed to go untreated; but, in making examination, the physician must go over the whole field, and find out all of the disease. Some of the cases in this series, years ago, would have been benefited if their uterine disease had been treated, granted the cause is systemic, for bad food is an etiological factor of uterine diseases; while treating systemically, use all of the modern means to attack the local pelvic troubles.

33. If men complain, and say this dietary is too rigid, we will only reply that the cases have demanded it, and will be very thankful when consumption can be cured by more pleasant means than we have employed.

TREATMENT.

Never prescribe raw beef.

Preparation of broiled chopped beef.—Take beef from middle of the top of the round of well-fed cattle, who were not overdriven just before death. In the handling of these chronic cases too much care may not be observed in the selection of beef; life often hangs on the smallest detail.

Cut beef into cubes one inch by one inch by two or three inches. Free from fat and connective tissue by running it through the Enterprise chopper three times, each time cleaning the fibrous tissue from the plate at the distal end of machine; or use American chopper, which is noisy, but is *the best.* Touch with the hands the muscle pulp as little as possible, as the human animal heat changes the character of the meat. Mould into cakes one inch thick, and as many inches wide as needed. Broil over bed of live coals, charcoal the best; oil or gas can be used. The beef when done should be of a very dark color outside, and when opened present a reddish, but not raw, appearance. If the beef is rightly prepared it will be pleasant to the taste. The preparation must be done by a conscientious, intelligent, and humble individual: humble, because most cooks think they know everything about cooking, when commonly they know nothing; and the one who has the work of getting ready this beef and cooking it has a position whose influence for good or bad cannot be overestimated.

Serve on hot water plate, and season with pepper, salt, lemon juice, Worcestershire sauce, and in some cases butter.

Drinks.—Drink one pint of spring or distilled water, that has been raised to the boiling point, one hour before each meal and on retiring. Cool the water to a comfortable temperature, and drink slowly. Rest till meal time; also after meals. The amount of water may be increased or diminished, as the urinometer indicates. The urine must be at 1,015 to 1,020 specific gravity, free from odor, phosphates, bile, or deposit. Drink clear tea or coffee at meals.

Baths.—Take ammonia sponge bath, one drachm to a pint of water, night or morning; or nitric acid

baths, same proportion; or aromatic sulphuric acid baths, same proportion. Quinine and salicin may be given in bath per skin. The acid baths, and especially with alkaloids, are indicated in sweats.

Exercise.—Passive, by massage, so as to confer force; also passive by riding in carriage; also by riding on a walking horse. Do not wear people out with too much walking. Sick ones need their nerve forces for something else.

Drugs.—The rule may be laid down, *that the fewer drugs given by the stomach the better.* Yet cases come where there has to be the most careful exhibition of medicines. And at times these same cases will, after taking a great deal of medicine, improve almost immediately on stopping all drugs per stomach. The integrity of the stomach must be kept at all hazards. Treating these cases one learns how to wait.

Tonics.—Salicin, strychnia, pyrophosphate of iron, cinchona, and mixtures of the mild vegetable fluid extracts. English iodide of potash in small doses in asthmatic and rheumatic complications, and in syphilis. Biniodide of mercury 1-16 gr., an admirable cholagogue. Exsiccated sulphate of soda for constipation. Boneset, etc., etc. *Each case is a law unto itself.*

In consumption, tumor, and cancer, the closer patients adhere to a rigid diet of the chopped broiled beef the better they will do. Sometimes the stomach rebels; this it does when the beef is not right, despite the protestations of the butcher to the contrary. On finally pressing the point you will disclose that the beef has been kept too long.

Again, the stomach needs firm discipline; there is a hysterical element in some cases (the word hysteria has been poorly used), which must not be catered to, but at times roughly handled. Prof. Wm. Goodell tells of how he stopped a patient vomiting by giving her a most cruel scolding. The rule is this, that the closer the lines are drawn the better will the patient do. No man need expect to succeed treating chronic disease if he has to argue with his patients on the right or wrong of this procedure.

When the urine becomes normal, the blood in good order, the physician may bring in gradually some vegetable food, as toasted bread, boiled rice. It has been said we are too rigid; but, gentlemen, each case is a law unto itself, and you must feed accordingly.

THE ARISTON, Broadway and Fifty-fifth street, New York.

THE WEST INDIES AS A SANITARIUM.

By WILLIAM F. HUTCHINSON, M.D.

I HAD intended, in closing my last chapter, to have spoken a few words upon the subject of clothing to be worn in the tropics and the amount of baggage to be taken.

In the first place, voyagers may place themselves entirely at ease in respect to custom-house authorities. All manner of courtesy is shown to tourists, and trunks or bags of any kind are rarely opened, officers going through the formula of chalking with the utmost rapidity and a pleasant smile.

In fact, at Martinique, the time occupied in passing my two trunks and two cameras was inside of sixty seconds; none of the packages were opened, and, with a courteous smile, the inspector said: "We never trouble the baggage of tourists, for there is no danger of their bringing anything here to cheat customs." And, the same being the case at all the other islands, there is no possible need to abstain from carrying as many trunks as one wishes. On board ship they are swung down into the hold, no extra charge is made for their transportation, and, arriving at one or the other central points aimed at, a depot may be readily established, and small baggage taken thence in any direction.

It is difficult to estimate the value of one's own clothes when away from home. There is a sentiment of placid content in the mind of the traveler who has all the changes that he wants that goes far to make him happy, while the one who has come away with a couple of suits only, soon finds that he has made a mistake.

It is not here as in Europe, where every pound of baggage must be paid for extra, at a rate that speedily makes one's necessaries cost more to transport than himself.

All due deference is paid to luggage in the British islands, and it is expected of the transportation lines that they should carry everything free.

It is a common thing to see a great boat-load of trunks going off on board a steamer of the Royal Mail, and to be told that these belong to a single passenger, when a casual observation would have convinced a looker-on that they were the entire baggage supply from a hotel. It is totally unnecessary to economize in this direction.

Under no circumstances, and I take the liberty to repeat this admonition, should anything but woolen underclothing be worn next the skin, and, bearing in mind the fact that West India washerwomen laundry their clothes by laying them on one rock and hammering them with another, it is as well to carry a supply sufficient for the trip, as I always do, or to purchase garments upon arriving, and to present them in fee simple to the laundress who comes to collect soiled linen.

The same rule holds good with gentlemen's flannels. There is no place in the West Indies where they can be cleansed as at home, and for this reason fancy tennis and yachting flannels are rarely seen among the natives, who content themselves with plain suits of blue or gray. Garments of white linen are rarely worn. It is a mistake to suppose that they are cooler. The expense of washing and repairing would be something enormous, they are quickly soiled, and not easily replaced.

Ladies in this climate rarely wear white, except at evening parties, or for morning wraps.

One begins by being surprised at the heavy clothing people wear down here, and end by putting on something of the same kind with exceeding joy, after an attack of lumbago caught by exposure to currents of air.

Serviceable flannel dresses for the day, cashmere gowns for breakfast, woolen or silk dresses for dinner, are what is needed. These, it is true, may be procured at a very reasonable price from native modistes, but they will rarely be satisfactory to the wearer anywhere away from the town where they are bought. It is better to take all that sort of thing along.

The same with shoes. The feet of the women of these countries are larger, on an average, than those of our own, and the ladies of my party found it a practical impossibility to reshoe themselves when their own boots had given out. Carry therefore plenty of boots.

In the French islands there are milliners who get up astonishing head-gear, some of the efforts made in Martinique being, as I was assured by a fair dame of our party, equal to anything she had seen in New York.

Do not take the trouble to bring umbrellas or sunshades. They may be purchased here in infinite variety, and at a price far below those at home. Everybody carries an umbrella, either for sun or rain, and no one is disappointed in not finding a use for them.

With this dissertation on the clothes that one has to wear and needs to carry, we will fancy the long and tedious voyage at an end, and the islands of Saba and St. Eustatius in sight.

Over Little Saba, often called "Napoleon's Cocked Hat," from its singular resemblance to that article of apparel, hung soft fleecy clouds, which presently saluted us with sharp rain gusts and in a moment shone out bright again.

No one seemed to know much about these islands, and I was glad, a little later, to get hold of a book about them, and meet a gentleman who had recently been there.

Saba's little colony of two thousand or more poor negroes live like sea birds in an eyrie, away upon the volcanic peak that climbs a thousand feet farther towards the sky. There they spend their idle lives, raising a few vegetables, and occasionally building a boat for fishing purposes.

Once in a way, there is diversion afforded them, for their mountain home has a habit of occasionally exploding; the last eruption, in 1869, having been severe enough to shake up the people of St. Thomas, fifty miles away, in an energetic manner, but without making any particular impression upon their own minds.

I heard also that this gentleman had been exported from Holland to Saba to get well of chronic bronchitis, and that he preferred the bronchitis to the cure.

As there is neither an hotel nor a boarding-house, nor much of anything else on the island, there is little to buy, and it is useless for tourists' purposes.

Only a little way, however, across a sea of absolutely tranquil blue, the mountain peaks of St. Kitts assume form against the sky. Above the rugged cliffs of Mount Misery dark clouds of smoke hung thick, with here and there a vision of flame, as the crater below talked to us.

From beneath the clouds to the very water's edge stretched down the fields of sugar-cane in softest, sweetest tints of living green, divided into fields by mere difference of color. Of all rapid thorough cures for sea-sickness commend me to pictures like these. Not one of the growlers who had been so troublesome all the way out, remained; every one was joyful, well and happy, and exclamations of delight were heard on every hand, with expressions of thankfulness that they had come.

Along the sloping hill-side, excellent roads shone white among the green. Here and there tall chimneys marked sugar estates, and deep gulleys in mountain sides told of furious floods in rainy times.

At last we came in sight of Basseterre, chief town and capital of the island, whose population is some thirty thousand souls, the island, not the city. Like all tropical towns, it is prettiest from the sea, if I except the well-kept public square and the garden around the church, which are singularly attractive to eyes dimmed to out-door beauties by long northern winters.

There, in February, Marechal Niel and Jacqueminot roses were blooming in open air in serene unconsciousness of frost and snow that was good to see, and in the park avenues, tall palms with graceful waving fronds of deepest green, and long lines of mango-trees, just then in full bloom, gave no hint of winter near.

The temperature was simply perfect; neither too hot nor too cold. It was a fitting environment to the natural graces of the beautiful island we were on.

The most thorough searcher for curios failed to find anything to buy, with the exception of a few specimens of tropical fruits, and the shops, to people who had just left Broadway, were scarcely worth mentioning; but to our sea-weary passengers it was Eden, and their ecstasies over the beautiful flowers and trees recalled some early experiences of my own when the tropics were new to me too.

Hotels there are none worthy of mention; but the government has made an offer of seven thousand pounds sterling to build one, and will purchase a suitable tract of land within a short time. The report from the present place that they call a hotel, of a gentleman who stayed there a week, is anything but encouraging. He says that the proprietor has a den opening out of the dining-room, in the door of which he makes his appearance in an inebriated condition at meal-time and berates the boarders; and they have tough chicken and fish, and nothing else, for twenty-one meals a week. They do seem to need a new hotel at St. Kitts.

Dr. Wm. J. Branch, who is the chief medical officer of St. Kitts, was courteous enough to give me the following information:

Average barometer range, thirty degrees, with low tide at 4 P.M.

During the hurricane months, which are August, September, and October, there is always more or less danger of cyclones, of which, in his experience of twenty-five years, there have been but two.

Average yearly temperature is 80° F., the hottest being in September, when the range of the month is 92°, and the coldest in January, when in the morning it averages 69°.

The average rainfall is sixty-two inches, being largely confined to the rainy season, which comprises the three months before mentioned. During this time the trade winds cease to blow, and rain falls, not continuously, but in frequent sharp showers. This is also the sickly season, prevalent diseases being diarrhœa and dysentery.

In all, to a population of thirty thousand, there are seven medical men, all of whom must have British qualifications; but, while it is essential that these qualifications should be held by any one before he can receive a government appointment, there would be no objection to any person holding a really good American degree practising in the island, as he would be backed up by the profession.

It should be borne in mind, in calculating the ratio of doctors to the people, that by far the greater number of the latter are poor blacks, who can afford to pay little or nothing, and it is therefore almost necessary that government appointments should be held, in order that the practitioner may live.

Fees are one dollar, each visit, within a mile, with a dollar mileage.

For obstetric cases, twenty-five dollars, including one month's attendance.

Surgical operations will vary as elsewhere, excepting that operative midwifery is fifty dollars. For surgery ether is almost always used, having taken the place of chloroform of late years.

There are no suits for malpractice. In the list of births and deaths, we find among the former for the quarter ending September 30, 1889, a total of births of three hundred and twenty-four, of which one hundred and seventy-five were illegitimate. It would not be fair, however, to permit this immense proportion

of illegitimate births to go out without some explanation. The fact is that, among a population with so large a proportion of blacks, the standard of morality is invariably low, and when, in the official report to his government, the chief medical officer finds it necessary to say, as he did on the 15th of March, 1884, that the polyandrous and polygamous system prevails almost universally amongst the peasantry at these islands, active prostitution is largely carried on in Basseterre, and the system of free love circulates among the peasantry, there can be, I think, no more striking commentary upon the condition of sexual matters made, and no further reason needed.

There is an excellent hospital, named for a former governor, Cunningham. It has one hundred and thirty beds, of which fifty are surgical, with well-ventilated, cleanly wards, furnished with neat iron bedsteads, and there is every evidence in and about it of careful and attentive supervision and skilful medical service.

One great drawback to the Cunningham Hospital is the mixed character of the institution. It is both a poor-house and a hospital, and this unfortunate mixture runs the death-rate up beyond its normal height. Again, it is a building for the reception of lepers, of whom I saw several therein; and these certainly deter other people who need hospital attention from going there. I trust that the time will soon come when throughout the West Indian islands sufferers from this loathsome disease will be isolated, and kept so. At present, among the most unpleasant sights are the ghastly apparitions of misery that meet one's eye, so full are the streets of sufferers from this awful malady.

There can be no doubt that the government—by which I mean the English Colonial Office—ought to provide such accommodations for its wretched subjects as will prevent any danger of the spread of this disease.

While I am upon this subject, leprosy, I feel inclined to ventilate modern opinions for and against the contagiousness of this disease.

I have before me an official inquiry made by the government of Trinidad into the condition of that island as affected by the disease, which presents features of the greatest interest. There is no doubt as to the fact that leprosy is increasing in the islands and decreasing in Norway, where simple precautions of isolation have procured a diminution of one-half the number of lepers in thirty-three years. On the other hand, it is about the same number of years ago that the first case was introduced into the Sandwich Islands, and on a single one of them are crowded together nearly forty thousand sufferers.

Contagion or non-contagion of leprosy has been long a well fought subject, and there are strong arguments upon both sides; but the crowning fact that seems to end the matter is that, where segregation is practised, its victims steadily become fewer, all other things being equal, and, without it, as steadily increase.

Let us go back a little in our steps, and with just a few words we will take leave of St. Kitts. It has the honor of being the mother colony of the British West Indies, having been settled by Sir Thomas Warner in 1623.

Excellent water is brought from the hills five miles away, and there is plenty of it. There are beautiful drives, and equally attractive rides, the most popular being the drive and climb up Monkey Hill, a sharp elevation on the south end of the island, where was once a strong fortification, whose ruins now are held by a garrison of apes.

Nevis goes fairly with St. Kitts, from which it is separated by a narrow arm of the sea, scarcely a mile wide. One should not leave St. Kitts without a visit to Nevis; for, beside the most wonderful hot spring and bath in the Windward Islands, there are the ruins of a once magnificent hotel, the birthplace of Alexander Hamilton, and a quaint old church in which I found the following record: "Married, March 17, 1783, Horatio Nelson, Esq., Captain of His Majesty's Ship 'Boreas,' and Frances Nesbitt, widow."

Besides all this, the visiting American, if he is as fortunate as I was, will meet cordial hospitality from Dr. Huggins and his charming Yankee wife.

So Nevis should by no means be neglected.

ST. KITTS, MARCH, 1890.

Society Notes.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, September 24, 1890.

THE VICE-PRESIDENT, JOHN B. ROBERTS, M.D., IN THE CHAIR.

RIB-FRACTURE FROM MUSCULAR ACTION, WITH FORTY COLLECTED CASES.

DR. JOSEPH P. TUNIS read a paper with the above title.

As fractured ribs form no inconsiderable part of those fractures which physicians are called upon to treat, some remarks on their rarer etiology may not be out of place. It is the object of this paper to report two recent cases where ribs were fractured, apparently from muscular action alone, and to collect together those which have already been published.

Different views have been expressed on the question whether a fracture can be caused, by muscular action alone, in bones not previously diseased. Some have positively denied such a possibility, as Richerand,[1] Vidal (de Cassis),[2] and Hornidge.[3] Others maintain a non-committal silence, as Petit,[4] Duverney,[5] Monteggia,[6] Desault,[7] and Bryant.[8] But the majority of surgical writers admit the possibility of such fracture, as Samuel Cooper,[9] Nélaton,[10] Malgaigne,[11] Purch,[12] Gurlt,[13] Follin,[14] Marchaud,[15] Erich-

sen,[1] Agnew,[2] Ashhurst,[3] Hamilton,[4] Gross,[5] Packard,[6] Stimson,[7] and others. We have the best authority, therefore, for believing that bones have been and will be fractured by muscular action alone, even in persons of good constitution. The elder Gross writes: "A diseased state of the bone is not at all necessary to the production of this accident."[8] Gurlt,[9] having collected a large number of the so-called "spontaneous fractures," confirms this view. Simon Paul,[10] also, and Professor Stimson in a recent *Treatise on Fractures.*

Moreover, in certain[11] instances where an autopsy was possible from some extraneous cause, a careful examination of the bones has demonstrated their healthy condition.

Of the one hundred and thirty-three cases collected by Gurlt, the majority had some condition present which rendered them more easily broken. Any condition which lowers the normal consistency and resistance of the bone structure must predispose to fracture, as osteomalacia,[12] rickets,[12] cancer,[12] syphilis,[12] scrofula,[12] advanced age (*i. e.*, over fifty),[13] or atrophy from continuous confinement,[14] etc. "In short, all diseases dependent upon cachexia more or less predispose to the occurrence of fracture," says Hamilton.[15] When some such cause is present the existence of a fracture from muscular action can be more readily accounted for. There are, however, numerous cases on record where such accidents have occurred in healthy individuals, the determining cause of fracture being muscular action, and the mechanism varying with the anatomy of the bone affected. If these conditions are true for other bones, why may they not be equally true for the ribs?

The ribs offer three factors favorable to fracture: *First*, by their shape, being long, thin bones; *second*, by their position, firmly attached at the vertebral, and more or less free to move at the sternal end, and *third*, by reason of the powerful muscles attached to their bodies. They are "elastic arches,"[16] it is true, and capable of considerable movement. But their elasticity has its limit, and their movement is dependent entirely upon the muscles attached to them. Of these muscles the diaphragm appears to be the most favorably situated to produce rib-fracture. Centrally attached by its crura and ligaments to the vertebral column, it is connected at its circumference "on either side, to the inner surface of the cartilages and bony portions of the *six or seven inferior ribs* interdigitating with the transversalis."[17] Take, for example, the ninth rib. If the diaphragm should contract it would draw the anterior third of this bone toward the vertebral column, the other two-thirds being held more or less firmly *in situ* by the serratus magnus, attached posteriorly, the internal oblique, the transversalis, and the intercostals. This contraction of the diaphragm continuing, if sufficiently powerful, would fracture the bone like a bent bow at the point of least resistance. Where the attachment of the serratus magnus left off, would seem a favorable seat for such a fracture. Has the diaphragm sufficient force to accomplish this? It has sufficient force to free the throat or bronchi of irritating material, almost approximating the sternum and the vertebral column in dyspnœa, often demonstrating clearly its power in membranous croup. It can eject forcibly the contents of the stomach on occcasion, or cause great distress, and even death, from obstinate hiccough. Well supplied with blood, exercised day and night, its actions uncontrolled, we may with some reason believe that, suddenly exerting all its force on three or four ribs, one or more may fracture. Certain it is that the ribs to which the diaphragm is attached are most frequently fractured (almost the only ones), and the circumstances which excite the action of that muscle are most often given as the exciting cause of the accident.

Above the sixth rib, other muscles enter into the mechanism of fracture. In the case which Dr. C. B. Nancrede[1] has reported, and in Dr. Bird's case,[2] where the second rib yielded under unusual muscular strain, the pectoralis minor seems to have been the most probable determining cause, as this muscle[3] is attached to the third, fourth, and fifth ribs, often to the second, and is inserted into the coracoid process of the scapula. If the scapula were firmly held in place by the powerful muscles attached to it, the pectoralis minor would be in a position to act with the advantage of leverage. This muscle, or the serratus magnus,[4] would draw the anterior third of the bone away from the vertebral column, directly opposite to the movement of the lower ribs under the action of the diaphragm. Thus the mechanism in the large majority of these cases may be reached. Some still remain which require a special explanation from the facts of the case.

Malgaigne[5] was the first to call attention to the possibility of rib-fracture from muscular action. He had collected eight examples (Nos. 1, 13, 14, 15, 34, 35, 36, and 37), of which he wrote: "I think it very probable that in all these cases the ribs had undergone more or less of the atrophic thinning of which I have before spoken; and that the fracture was induced by muscular action, which, in coughing, approximates the sternum and the spinal column, just as exterior pressure does." Paulet,[6] in his article "Ribs," of the Encyclopædia, gave six more examples (Nos. 2, 3, 4, 5, 17, and 18), and mentions five cases where the *costal cartilages* were ruptured by muscular violence.[7] Théophile Mazeille, in 1882, brought together twenty-four cases in tabular form.[8] Since then, so many additional cases have been reported that they number now at least forty.

The two recent cases here given have not been previously reported:

Mrs. D., fifty-two years old, in March, 1890, came to the Episcopal Hospital Dispensary, seeking relief

CASE II.—DISEASED BONES.

No. of cases.	Reporter.	Year.	Reference.	Sex	Age	Predisposing causes; physical conditions.	General condition.	Exciting cause.	Position of patient.	Diagnosis, side, rib, and site.
13	Nankevill,	1835	London Med. Gazette, vol xvi, July.	F.	63	Advanced age, malnutrition, and chronic bronchitis.	Weak and emaciated.	Coughing.	Lying in bed.	Left; fifth and sixth; anterior third.
14	Nankevill,	1835	Ibid; or Am. Journ. Med. Sci., vol. xvii,-xvii, p. 520.	F.	59	Advanced age, malnutrition,	Much emaciated.	Coughing.	Unrecorded	Left; tenth and middle third.
15	Berard,	1841	Lancette Francaise, 1841, No. 16.	F.	54	Suspected of syphilis, advanced age, and bad living.	Weak and emaciated.	Coughing.	Unrecorded	Left: ninth, tenth, and eleventh; anterior third.
16	Maingault,	1852	E. L. Beylard, Du Rachitis, etc. Paris, 1852, p. 76-83.	F.	35	Osteomalacia or rickets and malhygiene.	Anæmic.	Coughing.	Unrecorded	Three ribs.
17	Denonvilliers,	1853	L'Union Médicale, tome vii, No. 65, p. 258.	M.	55	Advanced age, pulmonary emphysema.	Emaciated.	Turning in bed.	Lying at full length.	Left; ninth; middle third.
18	F. Castella,	1861	Gaz. des Hôpitaux, No. 150, p. 599.	M.	39	Hereditary scrofula.	Strong looking.	Sneezing.	Seated at a bar.	Left; ninth; middle third.
19	Philip Miall	1871	British Med. Journ., Jan. 1871, p. 8.	F.	53	Tuberculosis, advanced age, pregnancy (primipara).	Anæmic.	Coughing.	Unrecorded	——; tenth; middle third.
20	Alexander,	1871	Ibid., p. 61.	F.	55	Advanced age, malnutrition, chronic bronchitis.	Weak.	Coughing.	Sitting at the fireside.	Left; eleventh; middle third.
21	Gillette,	1876	L'Union Médicale, No. 75, p. 1017.	M.	56	Tuberculosis and advanced age.	Third stage of phthisis.	Coughing.	Unrecorded	Left; eleventh; middle third.
22	Despres,	1882	Gazette des Hôpitaux, 1882, No. 25.	F.	53	Advanced age, chronic bronchitis.	Fairly good	Severe cough	Lying in bed.	Left; eleventh; anterior third.
23	Doit,	1882	L'Union Médicale, Paris, 1882, xxxiii, 676.	M.	59	Advanced age, tuberculosis, and syphilis.	Good.	Violent cough.	Sitting at his tailoring	Left; sixth; anterior third.
24	T. E. Underhill,	1884	London Lancet, 1884, vol. i, p. 1162.	M.	54	Great muscular development, advanced age.	Excellent.	Violent muscular action.	Erect, wielding a pick.	Left; sixth, seventh, and eighth; middle third.
25	H. C. Wyman,	1885	Journal American Med. Assoc., Chicago, No. 5, p. 512.	M.	72	Advanced age, bronchitis.	Good.	Sneezing.	Standing upright.	Right; eighth; near angle.
26	M. Desnos,	1885	Bull. et. Mém. de la Soc. Médicale des Hôp. de Paris, ii, 310-317.	M.	66	Advanced age.	Chronic bronchitis.	Violent cough.	Sitting on a bench.	Left; eighth; middle third.
27	Antony,	1886	Bull. et Mém. Soc. des. Hôp. de Paris, vol. iii, p. 247.	F.	63	Advanced age.	Chronic bronchitis.	Violet coughing.	Unrecorded	Right; ninth; middle third.
28	Ladroitte,	1886	La France Médicale, No. 95, vol. ii, p. 1133-1135.	M.	56	Advanced age.	Excellent.	Unusual muscular action.	Standing.	Right; fifth, middle third.
29	C. Tisne,	1886	Ann. Méd. Chir. Franc. et Etrang., Paris, ii, 286-293.	M.	68	Advanced age.	Chronic bronchitis.	Coughing.	Unrecorded	Eighth; at junction of middle and posterior third.
30	A. Kunos,	1886	Ann. Soc. de Méd. d'Anvers, xlvii, 383-386.	F.	66	Advanced age, small bones and large muscles.	Excellent.	Unusual muscular action.	Lying in bed.	Eighth or ninth; at junction of posterior and middle third.
31	S. A. Fisk,	1888	Boston Med. and Surg. Journ., No. 119, p. 325 (and a letter).	M.	32	Tuberculosis, diabetes insipidus, inflammatory rheumatism.	Vigorous looking.	Violent cough.	Seated sideways on a chair.	Right; tenth; middle third.
32	E. C. Masser	1890	British Med. Journ., London, vol i, p. 953.	M.	54	Advanced age, Bright's disease, bronchitis.	Feeble looking.	Coughing.	Unrecorded	Left; eighth; middle third.
33	Tunis,	1890	Unpublished.	F.	52	Suspected congenital syphilis, advanced age.	Emaciated, underfed, and overworked.	Coughing.	Lying on a sofa on her right side.	Left; tenth; middle third.

for a hacking cough and severe pain in the left side. Her emaciated figure, gaunt features, and parchment-like pock-marked skin, gave evidence of long-continued, mal-hygiene and mal-nutrition. Her family and personal history were negative, but her broad, flat nose, with deep triangular markings running off from it, made us suspect inherited syphilis. For the last three years she had suffered from rheumatism, but could remember no other sickness. Three out of her four children died in childhood. She stated that eleven days previous to her coming to the hospital, while lying on her *right* side on a lounge, she was suddenly seized with a violent fit of coughing. While coughing she felt a severe knife-life pain in her *left* side, and at the same instant something snapped "like a little stick." Not thinking it possible that she could have fractured a rib in such a manner, a sedative cough mixture was prescribed, and she was directed how to apply a turpentine stupe.

She returned the next day unimproved, and complaining bitterly of the pain in her side. A thorough examination of the chest then showed positive signs of fracture, of the tenth rib on the left side, about its middle. Dr. H. C. Simes, Dr. George Boyd, Dr. W. R. Lincoln, Dr. F. Rudderow, and Dr. L. H. Adler, Jr., afterward confirmed the diagnosis. There was no evidence of any direct violence in this case, and the patient gave a very clear account of the accident. Her cough was due to an attack of bronchitis. Strapping the affected side brought immediate relief, and she was discharged cured in six weeks.

Dr. Edwin Martin has kindly furnished me with the particulars of the following case, which was treated recently at the University Hospital Dispensary:

Fracture of Rib from Muscular Contraction.—James C. H., aged twenty-eight (about), a slender-built, muscular man, of healthy parentage, by occupation a laborer. By lifting a heavy beam, together with several workmen, the weight was suddenly thrown entirely upon himself. He was stooping slightly forward at the time, with his fingers grasping the bottom of one end of a beam; he was subjected to a sudden, violent strain. He heard a distinct crack, and felt an acute pain in the left side, as though a knife had been thrust in. The pain was greatly aggravated by breathing or coughing, and he distinctly perceived a sense of grating on motion. On examination, the sixth rib was found fractured at its sternal angle. There was no deformity, no ecchymosis. The patient was strapped, and made an uninterrupted recovery. There was no history of unusual brittleness in the bones of himself or in any member of his family.

For convenience, the collected cases, forty in all, have been divided into three classes.

CLASS III.—CASES WITH INCOMPLETE RECORDS.

CASE. 34.—Benjamin Gooch (*Medical and Chirurgical Observations;* Appendix. London, 1767. p. 53) reports: A young man at the hospital at Port Mahon, suffered from necrosis of a rib, caused by a kick. When nearly recovered he fractured a rib on the opposite side, during a paroxysm of coughing. He was much emaciated. Four surgeons diagnosed a complete fracture.

CASE 35.—M. C. Broussais (*Jour. Hebdomad.*, October, 1835, p. 107), at the examination at Val-de-Grace, of a patient suffering from chronic pneumonia and hypertrophy of the heart, found on the fourth rib a tumor of the size of a pigeon's egg, not painful. A fracture was diagnosed.

CASE 36.—M. Christy, senior surgeon of the hospital at Port Mahon, assured Malgaigne that he knew a gentleman who had fractured a rib in a violent effort at coughing (*vide* B. Gooch), (or *Archiv Générales*, Paris, 1838, vol. ii., 3d series, p. 272).

CASE 37.—Monteggia (*Institutioni Chirurgicale:* "Fracture," par. 17 and 23, 1802) saw a man about fifty, who had fractured a rib while coughing. The sound produced at the moment of fracture was heard by all in the room.

CASE 38.—Hilton (*Lancet*, London, 1852, i. p. 143) mentions a man who fractured a rib by muscular contraction while mounting a spirited horse. He was treated for pleurisy at first without relief.

CASE 39.—T. Mazielle in his thesis quotes a case supplied him by Th. Angers: A hat seller, forty-one years old, was admitted to Hospital Tenon with fracture of two ribs, apparently from muscular effort. The patient fell forward while walking, and only his head and one hand touched the ground. Signs of fracture in posterior portion of middle of thorax. No marks of direct violence.

CASE 40.—F. D. Bird (*Australian Medical Jour.*, May, 1889, p. 195) reports a married woman, with negative history, who fractured her second rib on the left side, about one and a half inches from the costal cartilage, while lifting one side of a heavy chest.

Deductions.—1. Forty cases having been reported, we may reasonably expect to hear of others, perhaps see them ourselves.

2. Of these accidents, more than one-fourth have occurred in individuals of apparently sound constitutions.

3. The left side has been most often affected, and either the middle or anterior third of the rib the usual position of the fracture. Of forty-nine fractures only five have occurred about the sixth rib. The great majority have been among the lower six (omitting the twelfth).

Rib Affected.

Second rib	2	Eighth rib	7
Fourth "	1	Ninth "	7
Fifth "	2	Tenth "	6
Sixth "	5	Eleventh rib	7
Seventh"	3	Unrecorded	9

Side Affected.

Right side	10
Left "	19
Unrecorded	11
Total	40

4. The exciting causes have been; Coughing (twenty-five), muscular effort (eleven), sneezing (three), and vomiting (one). The determining cause has been the action of the muscles, unless thirty-four observers have been deceived by the testimony of patients who could gain nothing by such deceptions.

5. Herard reports the youngest example (Case 2) of this accident, a woman, twenty-two years old. No case has been published younger than this—no doubt on account of the great elasticity of the ribs in youth.

6. Of these forty cases, two died of some intercurrent affection. The remaining thirty-eight made a complete recovery in the usual time.

7. More men (twenty-two) have suffered than women (seventeen), and the average age has been forty-eight years.

The difficulty and doubts which have attended the diagnosis of many of these cases ought to disappear, as more and more examples of this accident are re-

ported. Already, by the consent of the majority of surgeons, and by the evidence of accumulated cases, the possibility of rib fracture from muscular action, even in persons of sound constitution, seems sufficiently proven.

Discussion.—Dr. O. H. Allis: I have been both interested and instructed in the paper. I am interested in the fact that so many fractures of the ribs produced by muscular action have been reported by the speaker. I think there are no long bones, where fractures from muscular action are so infrequent. I think that fractures of the humerus from muscular action occur in the proportion of at least ten to one as compared with fracture of the rib. The reason of this is, I think, because the ribs are so greatly protected. I think that the reason the diaphragm does not fracture the ribs more frequently is because its fibres are all short. There is a central tendon which divides the muscle. If it arose at the back and extended to the front, fractures of the ribs would probably be more frequent.

The subject of muscular laceration would also be a good subject to investigate. We so often find an abscess; it may be in the abdominal walls, due to laceration of one of the abdominal muscles. We see the same thing in various parts of the body. The fact that all these fractures are low down would seem to indicate that the diaphragm had a great deal to do with them, and, possibly, that the abdominal muscles also acted with it.

RAILWAY SURGEONS' ASSOCIATION.

The Pennsylvania Co. Railway Surgeons' Association held its annual meeting in the parlors of the Seventh Avenue Hotel, at Pittsburgh, Pa., on Tuesday, the 14th day of October, with a good attendance.

Dr. J. J. Buchanan read a valuable paper on

WHEN TO AMPUTATE,

in which he limited his subject-matter solely to injuries (not disease), requiring amputation. He said that it is better to wait until shock subsides. That in case of fragments of limb below point of crushing, and still adhering, they should be immediately *removed at seat* of injury; ligate all bleeding vessels, and then wait until shock subsides before proceeding to amputate.

Drs. Murdock, Ridenour, and others doubted the propriety of this.

Drs. Ridenour, Larkin, Mosael, and others favored immediate amputation, provided patient was not in a state of collapse, as in cases where a large joint—such as the knee—is involved in the injury, the shock will naturally become deeper the longer you wait.

S. S. Thorn, M.D., of Toledo, reported a case of cerebral surgery, wherein a patient's life was saved by a resort to trephine, after weeks of suffering following a slight injury to head.

The retiring President, Dr. J. B. Murdock, of Pittsburgh, Pa., delivered a fine valedictory on the benefits resulting to the railway surgeon from these meetings of the Association. He made the excellent point that each and every railroad surgeon should attend these meetings; that those who did not, belong either to that *dangerous* class who know too much, or else to the *sloth* and sluggard—both not good for their position.

The following officers were elected for the ensuing year: *President*, S. S. Thorn, M.D., of Toledo, O.; *Vice-President*, Dr. Milo, of Newcastle, Pa.; *Secretary and Treasurer*, S. P. Post, of Canton, O.; *Executive Committee*, Dr. Larkin, of South Chicago, Ill.; Dr. A. W. Ridenour, of Massillon, O.; Dr. J. B. Murdock, of Pittsburgh, Pa.

Society adjourned to meet in Chicago in the third week in October, 1891.

Treatment of Chronic Bright's Disease.—In the Section for Internal Medicine, at the International Medical Congress of Berlin, the subject of the treatment of chronic Bright's disease was brought forward for discussion. Dr. Lépine, of Lyons, opened the discussion. The danger of a chronic nephritis being the insufficiency of the renal secretion, the principal indication is to overcome this insufficiency. But in favoring increased secretion of urine care must be taken not to put too much work on the already diseased kidneys. On the other hand, it is necessary to keep up the nutrition. We must nourish the patient and stimulate the secretion of urine without irritating the kidneys—two indications which seem to be opposed, but which can yet both be satisfied. In the matter of food, we must diminish the amount of albuminoids relatively to the hydrocarbons and fat, since the waste products of the latter are not excreted by the kidneys. Although it is theoretically somewhat too rich in albuminoids, nevertheless milk is the best food for the patient with kidney disease. It contains no waste materials, and all the nitrogenous substances are utilized in the economy; it is rich in fats, contains nothing which can irritate the renal epithelium, and finally is diuretic. But it is usually impossible to keep the patient on a pure milk diet, and it will be found necessary to supplement it with digestible vegetables, bread, farinaceous foods, etc. It is, above all, important to attend to the condition of the digestive functions, since when the digestion is poor many toxic principles are formed which will serve only to irritate the kidneys. Although albuminuria is a symptom of transudation and apparently independent of the amount of secretion, yet we do not know what the relation between the two is, and it is therefore prudent to restrict the patient in the use of eggs, and sometimes of fish, if these appear to increase the amount of albumin excreted. To favor diuresis we may have recourse to slightly alkaline mineral waters, which sometimes are sufficient for the purpose. But when the diminished secretion is accompanied by signs of cardiac weakness we must employ heart stimulants. In the first rank of these remedies the author placed crystallized digitalin. This should, however, be given with great caution, and only every other day or even at longer intervals, in order to insure its complete elimination. Caffeine, in doses of at least fifteen grains hypodermically, was sometimes of service. Strophanthus should not be given, since it had a tendency to irritate the kidneys. Iodide of potassium, which is a diuretic, is chiefly indicated when there is arterio-sclerosis. The author was opposed to the employment of vapor-baths in cases of dropsy, fearing uræmia, but he always advised rest in bed, by means of which an even temperature of the skin could be maintained. Of course it was necessary to avoid all exposure to cold and wet. Uræmia was what every patient with chronic Bright's disease had most to fear.—*Med. Record.*

Dr. B. H. Diehl, of 2151 Park avenue, Philadelphia, died October 17. He was a graduate of the Medico-Chirurgical College, and had been in practice but little more than a year.

DR. BARTHOLOW'S RETIREMENT.

MUCH surprise was occasioned last week by the announcement that Dr. Roberts Bartholow had been requested by his colleagues to resign the chair of Materia Medica and Therapeutics in Jefferson Medical College. The reason for this step, it is intimated rather than distinctly stated, lies in a degree of mental aberration which is alleged to render Dr. Bartholow unfit for the position he occupies. This is indignantly denied by him, and the resolutions adopted at a meeting of the students affirm that his teaching is fully up to the standard of his previous efforts.

If it be true that Dr. Bartholow is failing, it is a kindness to retire him while there is still a chance that rest and quiet may restore him to health; and this is no less a kindness if the object is unconscious of the need for such treatment. But if, as Dr. Bartholow avers, this is simply an excuse to get rid of an undesirable associate, a great wrong has been done to him.

Under the present wretched system of organization, the teachers in unendowed medical colleges must be prepared each to "hold up his end,"—*i. e.*, to sustain his share of the common burdens in the competition with rival institutions. If a lecturer grows old-fashioned, uninteresting, or cranky, so that students desert his class-rooms for those of more popular teachers, the stern law of the survival of the fittest demands that he give place to a better. By means of this dropping out of the least desirable member, the personnel of a faculty is sometimes completely changed in a few years. Individually it may be a hardship; but the world has no use for drones or weaklings, and the interests of the institution and of its students are best considered by this plan. Nobody rests contentedly on the laurels he has won, but a fresh competitor steps into his place. Young Absalom is always eager to push old David from his throne.

But if these are the reasons for a man's retirement, it is better that they should be stated, in justice to the man displaced. For a man may cease to be popular as a teacher, and yet be still very desirable as a practitioner; while nobody cares to entrust his life to a man who is demented.

Dr. Bartholow has for many years filled a large place in the public eye. In Cincinnati he made warm friends and bitter enemies. His book on Therapeutics gave him the reputation that brought him to Philadelphia. In this work he did a great service to the profession. Coming out at a time when therapeutic nihilism was prevalent, his confidence in his methods of treatment and the emphatic language in which he couched his assertions won a hearing for him at once. Here was a man who believed in drugs, who could utter and print an emphatic "will," instead of Flint's "perhaps." There was a vigor about his therapy that "took." He used knock-down arguments in combating disease, and his forty-grain doses of quinine sometimes won the battle, where a temporizing policy would have lost. To him disease was an entity, a personal enemy, and he had full faith in his own powers. He confidently promised "cures" of all sorts of ailments, and even in the most hopeless he found remedies of "great value" in their treatment. Pity that such bright anticipations were not always realized; but we have no doubt that the percentage of recoveries for a physician imbued with such faith is far greater than for one equally skilful whose views are pessimistic. Then, too, his views were helped wonderfully by his introduction to the profession of many drugs previously used only in irregular or domestic practice. Before deciding that his views were too sanguine, it was necessary to ascertain by trial the properties of the new agents he recommended. In this Dr. Bartholow conferred a great boon upon the profession. While but little of his work will find a permanent place in the field of practice, he has exerted the most powerful and the most beneficial influence upon therapeutics of any writer of this generation.

As successor to Dr. Bartholow, it is said that the choice has fallen upon Dr. Hobart Amory Hare. Dr. Hare is a young man in medicine, his diploma bearing the date of 1884. He has repeatedly distinguished himself as an essayist, winning honorable prizes in competition with writers from all parts of the world. His selection by the Leas to fill the place of Dr. Hays as editor of the *Medical News* showed the estimation in which he was held by that influential publishing house. Dr. Hare has just issued a work on Therapeutics, which is now in the hands of a reviewer of our staff. Whether he will be able to "hold up his end" in competition with his master, Dr. H. C. Wood, remains to be seen.

And this brings on another question, more important than that of the change in a faculty chair: How is Jefferson College, with a faculty of seven active men, going to organize a three years' graded course with over five hundred students? The University finds a corps three times as large necessary. The Medico-Chirurgical College, with only one hundred and twenty-five students and a faculty of sixteen, and a thoroughly capable and efficient corps of assistants, finds it a task of such difficulty that their energies are taxed to the utmost. Either Jefferson

must open her faculty by creating new chairs and thus dividing the work, or her professors are men of gigantic mental and physical strength.

Annotations.

MATTERS sometimes turn out quite differently from what the planner expects, as has been noted by many observers before and after Burns. India has been held up as the earthly paradise of female doctors; the sex and religion of males excluding them from the zenana. But now we are told that in the Lucknow hospital the female patients turn up their small noses at physicians of their own sex, and prefer to enter the wards presided over by men. It is true that these patients are usually of the lower castes; but human nature is the same in every station; and it is quite likely that the Ranee or Sultana will also prefer a male medical adviser, and find a way to secure his services, spite of caste or Koran.

THE *Inquirer* proposes that in view of the certainty with which typhoid fever can be prevented from spreading, by disinfecting the excreta of typhoid patients, an association of citizens shall be formed to look after the disinfection of cases occurring along the Schuylkill river. By this means all danger of infection from that source could be obviated.

The idea is a good one, and could easily be carried out at an expense that would be trifling beside that of constructing an aqueduct from Trenton. But would it not be well to begin by enforcing such a system within the city, and thus prevent infection of our sewers? It is almost certain that typhoid fever could be stamped out by such disinfection, as certainly as small-pox is by vaccination. The scientific demonstration of this fact has now become sufficiently positive to warrant legislative action which would render the disinfection of typhoid excreta compulsory.

IN the *Journal of Dermatology* Dr. Luff describes some experiments made with a view of ascertaining the absorption of drugs from ointments made with vaseline, lard and lanoline as bases. The ointments were placed in sheep's bladders and suspended in distilled water, kept at a temperature of 98° F. The result showed that exosmosis of potassium iodide began most quickly from the vaseline, and not at all from lanoline. The same result ensued with carbolic acid. The wholly unwarranted conclusion is drawn that when absorption is desired, ointments should be made up with vaseline.

This is opposed to the results obtained by a series of trials at the Medico-Chirurgical Hospital. Ointments of atropine were prepared with lanoline, oleated lard, pure lard, vaseline and mollin. These were rubbed upon the skin of patients selected with a view to uniformity as to age, quantity of ointment used, etc. The trial showed that the lanoline ointment was most quickly followed by the symptoms of atropine—the dry throat and dilated pupil. Next came the oleated lard, while vaseline and mollin came last.

THE "KREUTZER SONATA" AND RUSSIAN MORALITY.

A GOOD deal of the disgust excited by Tolstoi's "Kreutzer Sonata" would, no doubt, have been saved were the readers familiar with the state of affairs in Russia. It is a fair inference that the author could not have written such a book unless the conditions in which he lived were very different from anything to be found in America. A writer in the *Fortnightly Review*[1] gives a glimpse of Russian life which goes far towards explaining the *raison d'etre* of Tolstoi's book. We are forcibly reminded that the Slav is as yet an undeveloped member of the Aryan family; and the degree of truth in this statement may be estimated by tracing back the history of any sister race until the same condition is found. Indeed, the limits of history will be reached, in some cases, before such a degree of brutish sensuality is found to prevail. It has been said that in the middle ages a condition of universal priapism existed; but we have even here the evidences of a contrary sentiment prevailing, in the rise of chivalry, which carried the idea of personal purity to a height rarely equaled in modern times. The fierce viking shut out women altogether from his cities. The Syro-Greek, in the groves of Antioch, invested his sensuality with a poetic grace that still survives in history. Chastity characterized the German on his first appearance upon the world's stage. The debauchery of the Roman Empire was unparalleled; but what magnificent achievements of that race preceded and led up to it! The race that built up the most stupendous political fabric the world has ever seen was as terrible in its excesses as in its battles. Celtic immorality is a modern development; and among the Gaelic population of Scotland, Ireland and Wales, chastity is the rule, with rare exceptions. But to-day, in Russia, Pachmann says that "the district courts do not look upon adultery as a serious violation of conjugal rights." Lanin speaks of the "abyss that separates Russian notions of morality and decency from those that prevail in the West." A parish priest, writing in *Graschdanin*, says: "All their social relations are permeated with coarse, cruel, brutal egoism." So that Tolstoi's book, necessarily a sharpened dart, hurled with full strength, may serve to pierce the tough Russian cuticle and arouse the sensation of conscious guilt.

RAILWAY SURGERY.

THE relations of the railway surgeon to the traveling public are considered in a paper presented to the Association of Railway Surgeons by A. W. Ridenour, of Massillon, Ohio. In case of injury by accident, the author states that patients may be transported by rail, for considerable distances, as soon as the preliminary dressings have been made. The motion of the car acts as a stimulant to patients in shock; though the time of transportation should not exceed two hours, as fatigue is then manifested. He earnestly warns against the practice of unlimited stimulation. A little whiskey may be beneficial if carefully administered. Besides this, hot water or beef tea, externally or internally, will do more good.

All trainmen should receive instruction in "first aid to the injured." Amputations should receive the sanction of the patient and his friends. In case of injury to any part of the nervous system, the physician should be discreet in expressing any opinion. The results of such injury may be far-reaching, and slow to develop. Real injury will inevitably be followed by demonstrable tissue alterations. These cases should be watched for one or two years. He ridicules the idea of bacteria clinging to the furniture

[1] Literary Digest, October 18, 1890.

of a sleeping-car. All bedding is thoroughly cleansed and disinfected at the end of each trip. Some improvement could be made in the closets, which are generally open and expose the persons using them to drafts. In case of menstruating women, in winter, this might cause trouble; but by a simple improvement this could be obviated.

Without great care, filthy and undesirable persons may avail themselves of the privileges of the sleeping-car; but the officers generally prevent this. If not, thorough cleaning is universally enforced at the earliest possible moment. But one bed should be made up in a section, if possible; the ventilation should be above and below; the temperature should be maintained at 65° F., instead of 98°, as is the porter's preference; and the bed should be arranged with the feet towards the engine.

Dr. Ridenour's paper shows that he has given his subject much study; and the suggestions made could be adopted with benefit. There is no doubt that both health and comfort would be much enhanced were the upper berth to be done away with; but a serious objection would be found in the increased cost, as the car would then accommodate but half the present number. This, however, would be more apparent than real, as a sleeper is rarely more than half full; the swaying of the top berth being too much for any but a seasoned traveler. Sleeping-car officials, however, insist on making up the top berths, even when not occupied, unless the occupant of the lower berth pays for the section.

Letters to the Editor.

CARDIAC OSSIFICATION.

I WAS recently called to see the body of a man who had been found dead. From the appearance of the body I concluded that he had been dead about an hour, or possibly two hours. Being ordered by Coroner Franklin to make an autopsy I proceeded to do so, and found the contents of the abdominal cavity normal. On opening the chest I found numerous old pleuritic adhesions, and the heart was very much enlarged, of a yellowish color, and full of fluid blood. On removing the heart, and laying open its cavities, I found the left auricle encircled on the inner surface by a ring of ossification, three-fourths of an inch wide, and extending almost the entire distance around it. How the heart continued to function so long is a mystery. The cause of the cardiac hypertrophy was evidently aortic stenosis.

WOODBURY, N. J.

Book Notices.

ESSENTIALS OF PRACTICE OF MEDICINE. By HENRY MORRIS, M.D.; with an Appendix, on the Examination of Urine, by LAWRENCE WOLFF, M.D. Philadelphia: W. B. Saunders, 913 Walnut street, 1890. Cloth, pp. 368 and 66. Price, $2.00.

A quiz compend, like all the rest on practice, about ten years behind the times. If a fair specimen is to be found in the chapter on muscular rheumatism, the teaching is neither sufficient nor correct.

SAUNDERS' POCKET MEDICAL LEXICON. By JOHN M. KEATING, M.D., and HENRY HAMILTON. Philadelphia: W. B. Saunders, 913 Walnut street, 1890. Cloth, pp. 280.

A really good, little, vest pocket lexicon, in much larger type than usual; but the paucity of words necessitated is largely made up by the good judgment shown in their selection.

Pamphlets.

A Criticism of Willett's Operation for Talipes Calcaneus. By A. B. Judson, M.D. Reprinted from the *New York Medical Journal* for August 23, 1890.

Clinical Observations on Salpingitis. By Thomas A. Ashby, M.D., of Baltimore. Reprinted from the *Maryland Medical Journal*.

I. The Prevention of the Short Leg of Hip Disease. II. The After-Treatment of Hip Disease. By A. B. Judson, M.D., New York. Reprinted from the Transactions of the American Orthopedic Association, September, 1889.

The Medical Digest.

NOMA FOLLOWING TYPHOID.—In the *Lehigh Valley Medical Magazine* Keim describes a fatal case of gangrene of the cheek following typhoid fever, in a boy aged nine years. This rare affection has been most frequently noticed as a sequel of measles.

FOR CIRRHOSIS OF LIVER.—

℞.—Hydrargyri bichlorid	gr. j.
Ammonii muriat	ʒij.
Syr. aurantii	℥j.
Aquæ	q. s. ad ʒiij.

M.—S. ʒj thrice daily.

—Satterthwaite, *Southern Med. Record.*

TRAUMATIC TETANUS.—Tancil (*Jour. Am. Med. Asso.*) reports the case of a boy with tetanus, following a wound of the foot. Recovery ensued under the use of quinine, bromidia and gelsemium. The physicians in attendance credited the cure largely to the bromidia, which was given in doses of a teaspoonful every one, two or more hours, as needed to control the paroxysms.

FOR DIABETIC GINGIVITIS.—

℞.—Acid. borici	25 grammes.
Acid. carbolici	1 gramme.
Thymolis	0.25 "
Aquæ	1 liter.
Misce, et adde :	
Sp. anisi	10 grammes.
Sp. menthæ pip.	10 gtt.
Alcohol	100 grammes.
Cocci cacti	q. s. ad colorando.

S. To be diluted with an equal bulk of water and used to rinse the mouth after meals.

—Dujardin-Beaumetz, *Therap. Gaz.*

ITCHING.—Bronson (*Med. Record*) thus summarizes a paper on the sensation of itching:

1. That there is a sense of contact independent of the sense of pselaphesia.

2. That this sense of contact is the sense disturbed in pruritus.

3. That it concerns primarily, simple cutaneous nerves or nerve-endings, situated superficially and probably in the epidermis.

4. That the disturbance in pruritus is of the nature of a dysæsthesia due to accumulated or obstructed nerve excitation with imperfect conduction of the generated force into correlated forms of nervous energy.

5. That scratching relieves itching by directing the excitation into freer channels of sensation, sometimes, especially when severe, substituting for the pruritus either painful or voluptuous sensations.

6. That the voluptuous sensations that may attend pruritus are a manifestation of a generalized aphrodisiac sense, representing a phase of common sensation that has its source in the sense of contact.

OVARIOTOMY FOR THE CURE OF INSANITY.—Pfaff (*Weekly Medical Review*) describes a case in which he removed the appendages, which were diseased, from a woman who was at the time in acute mania, caused, it was thought, by the ovarian disease. The results are given as follows: "Since this time, a period of four months, she has continued to discharge the ordinary duties of housewife, without any symptoms, so far as can be ascertained, of her former mental derangement; and I have just this week seen her family physician, who assures me that his patient has been entirely cured by the operation, and that her mental faculties are as bright, apparently, as they ever were."

FOR DIABETES.—

℞.—Fel. bovis inspis.
Quininæ sulph. .....āā gr. xl.
Ext. nucis vomicæ ..... gr. vj.
M.—et in capsul. No. xx divide.
S. One before each meal.

℞.—Ext. hyoscyami fl. ..... ℥iij.
Ext. damianæ fl..... ℥vj.
Potassi bicarb. ..... gr. xl.
Mucilaginis..... ℥ss.
Aquæ..... ℥iij.
M.—S. ℥j every three hours.

Restriction of the quantity of food is more essential than of its quality.

—Porter, *Southern Med. Record.*

ADMINISTRATION OF CHLORALAMID.—Much depends upon the proper administration of the new hypnotic, chloralamid, to obtain the full effect and satisfactory and beneficial results. The dose is from 15 to 60 grains, with an average dose of 30 grains. Chloralamid is soluble in about 20 parts of cold water, and in 1½ parts of alcohol.

An additional caution is necessary: *Never dissolve or dispense chloralamid in hot water or warm solutions*, as the heated preparation decomposes.

The best modes of administration are:

1. In a tablespoonful of whiskey or brandy.
2. In properly proportioned solutions with wine, spirits, or spirituous compounds.
3. In a small cup of cold water or cold tea.
4. In powder form, in wafers or cachets washed down with cold water.

TOXIC EFFECT OF CALOMEL IN THE PRESENCE OF CHLORIDES OF THE ALKALIES.—Adam (*Nouveaux Remèdes*) confirms the statements of such authorities as Moll, Hervé, Guibourt, Larocque, Jolly, and others to the effect that within the body calomel does not, to any appreciable extent, go into solution as sublimate. M. Mialhe's assertion that it does, and that the agent in effecting this is sodium chloride, is still current doctrine. Dr. Adam's experiments were made both in the absence and presence of organic matter; in either case only traces of mercury went into solution provided that there was not free access of air. In the presence of air a considerable quantity of mercury was dissolved. The author claims that within the body the access of air is practically *nil*. Besides experiments outside the body, others were made on the living animal which confirmed the above negative statement.—*Brit. Med. Journ.*

SPINAL CONCUSSION.—Dr. Watson intelligently discusses many of the problems which this series of experiments presents. We deem his conclusions of sufficient importance to present them in outline as follows:

1. Concussive accidents never produce pathological changes in the cord unless great force has been applied to the spine. These cases are generally complicated with vertebral fracture or dislocation, rupture or stretching of vertebral ligaments, or distant injuries so severe as to quickly prove fatal.
2. The symptoms develop immediately, and are rarely intensified by morbid changes in the cord; exceptions, fractures, dislocations, and slowly developing hemorrhage causing pressure on the cord.
3. It is very difficult to demonstrate stretching of vertebral ligaments on living subjects. The lesion is frequently overlooked on autopsy.
4. Injuries of the cord, with visceral injuries in addition, develop symptoms dependent on the existing complication. The termination of the case rests on the character of the traumatism.
5. Concussive force, though remotely applied, frequently results in the production of severe and even fatal traumatisms in various organs within the three trunk cavities.—*Med. Record.*

BACILLARY PARTNERSHIPS.—In the course of some experimental investigations on the relationship of micro-organisms with diseased conditions, Drs. Cornil and Babès have discovered that a certain affinity exists between particular species. In other words, the development of special varieties may be facilitated, or the reverse, by the presence or pre-existence of certain other varieties. In this way the occasional complication of an existing infectious disease by a second is not the result of mere chance, but is governed by some still undefined conditions of environment. In other instances this association of two or more species of micro-organisms is necessary to the evolution of the malady. This association is the rule in the infectious diseases of human beings, and it is often the secondary infection that determines the fatal issue. This partnership arrangement may take place between microbes belonging to more or less nearly related species, as in the case with the organisms of pneumonia and typhoid fever. Or there may be streptococci and bacilli together, as in diphtheria, or several varieties of streptococci, as in the infection of wounds. In fact, there is a large selection of these associations, some invariable, others frequent and a third category, in which the secondary infection is accidental. These facts may possibly throw some light on the rhythm and sequence of the symptoms in the infectious diseases.—*Med. Press.*

CHLOROFORM.—I will conclude by giving a series of "practical conclusions," derived from studies of the subject by experiment upon animals, which do agree with observations upon the human subject. And I consider it a matter of no slight congratulation that they were presented at the late International Congress by one of our countrymen, Professor H. C. Wood, in his address on anæsthesia. They have been lately published in nearly all the journals, but they will bear repeating. The closest examination fails to detect any flaw in them, or to find any point which is not supported and which cannot be substantiated by clinical records:

1. The use of any anæsthetic is attended with an appreciable risk, and no care will prevent an occasional loss of life.
2. Chloroform acts much more promptly and much more powerfully than ether, both upon the respiratory centres and upon the heart.
3. The action of chloroform is much more persistent and permanent than that of ether.

4. Chloroform is capable of causing death either by primarily arresting the respiration, or by primarily stopping the heart, but commonly (sometimes) both respiratory and cardiac functions are abolished at or about the same time.

5. Ether usually acts very much more powerfully upon the respiration than upon the circulation, but occasionally, and especially when the heart is feeble, ether is capable of acting as a cardiac paralyzant, and may produce death at a time when the respirations are fully maintained.

6. Chloroform kills, as near as can be made out, proportionately four or five times as frequently as does ether.—Reeve, *Medical News.*

Examination of the Sputum for Tubercle Bacilli.—Kühne, of Wiesbaden (*Centralbl. fur Bakt. und Parasitenk.*), after referring to the fallacies and difficulties with which the search for tubercle bacilli in sputum from phthisical patients is surrounded, describes a new method of staining the bacilli. When it is difficult to spread out the sputum on a cover glass he uses a concentrated solution of borax, to which at least an equal quantity of sputum is added. The mixture is shaken up in a suitable glass or is worked up in a mortar, after which it is easily spread in a thin layer over the cover glass. Nummular sputa from cavities may be broken down by a watery solution of carbonate of ammonia; this has the advantage that it is partially volatilized as soon as the cover glass is heated, and what remains is broken up by the action of the acid. An equable layer on the cover glass being obtained, the albumen is coagulated by careful heating over a flame, after which the specimen is stained in Ziehl's fuchsin solution for five minutes, the color is completely removed with a 30 per cent., solution of nitric or sulphuric acid, and the specimens are washed in water and dried. In order to obtain a contrast stain, two or three drops of a concentrated solution of picric acid in aniline oil may be added to a watch glass containing pure aniline oil; a drop of this, placed on the slide before the cover glass is lowered into position, gives a sufficient yellow contrast stain to cause the red tubercle bacilli to stand out very prominently. They may be examined with a magnifying power of × 60 to × 100, and where they are in great number, as is the rule in "cavernous" sputa, they appear under still weaker magnifying power as particles of red dust on a yellow ground. To make a permanent preparation, Kühne recommends that the aniline oil be driven off by means of his hand blower, and that the specimen be mounted in Canada balsam. By this method the tubercle bacilli only are stained.

—*British Med. Journal.*

Pancreatic Digestion in Marasmus.—Gillet has examined the activity of the pancreas removed during cold weather, shortly after death, from seven children. His results, as reported in the *Annals de la Policlinique de Paris*, are worthy of note, though his cases are too few to allow any conclusion to be drawn.

1 and 2. Two of the children were twenty-four days old when they died of "congenital debility;" in both the action of the pancreatic extract on starch was very slight; and in the one case in which the emulsifying and proteolytic action was tested, both were very imperfect.

3. In a child, aged fifty-three days, who died of athrepsia and bilious diarrhœa, starch and casein were very slowly acted on, but oil was emulsified.

4. In a child, aged three months, who died of lienteric diarrhœa, there was no action on starch, casein, or oil.

5. In a child, aged eight months and a half, whose death was due to congenital debility, starch was reduced in ten minutes.

6. In a boy, aged twenty-two months and a half, who died of pulmonary tuberculosis, albumen was rapidly dissolved, but the action on starch was delayed and on oil was imperfect.

7. In a boy, aged three years and a half, who died of measles and diphtheria, starch was reduced in twenty minutes.

M. Gillet, as is right, refrains from stating any definite conclusions, but considers that these results tend to support previous observations as to the inactivity of the pancreas during the first months of life, and to show that in lienteric, and perhaps also in bilious diarrhœa, it loses its power of acting on starch and albumen, while this power is retained in such severe diseases as "tuberculosis, measles, and diphtheria." His experiments were carefully performed, and precautions were taken to render the fluids aseptic.

—*Brit. Med. Jour.*

Intestinal Obstruction.—Jessett (*Med. Press and Circular*) thus sums up a valuable article:

1. Obstruction of the intestines the result of constricting bands or volvulus are always met with either in the small intestine or the sigmoid flexure.

2. The most common cause of bands are old peritonitis, local or general, Meckel's or other diverticula may be the cause of constriction of the bowel by snaring or twisting.

3. The predisposing cause of volvulus consists in elongation of certain segments of the intestine, abnormal length of the mesentery, adhesions, or unequal peristaltic action.

4. The higher in the intestine the obstruction the more severe usually are the symptoms.

5. All cases of obstruction should be treated by early abdominal section, and if possible reduction of the constricted portion of the intestine by dividing of constricting bands or untwisting a volvulus, that is if the gentle insufflation of hydrogen gas fails to effect reduction.

6. In all cases where the intestine is very distended, it should be freely incised and its contents evacuated.

7. In all cases in which the constriction is irreducible lateral anastomosis by approximation discs should be practised so as to exclude permanently the seat of obstruction from active fæcal circulation.

8. In cases where gangrene has taken place in the loop of constricted intestine, it should be excised, and the portion of intestine above and below the seat of constriction should be united by lateral anastomoses by approximative plates; the divided ends being invaginated into themselves.

9. All bands and diverticula should be removed when practicable at the time of the operation; in the case of volvulus, if the mesentery is abnormally long it should be shortened.

10. That enterostomy, or the formation of an artificial anus, should never be performed unless it is found to be absolutely impracticable to re-establish the continuity of the intestinal canal by dividing the constricting bands by enterorrhaphy or by means of lateral apposition as described.

Celluloid has proved a failure as a material for artificial eyes.

Medical News and Miscellany.

SCARLET fever is on the increase in London.

ALEPPO reports fifty deaths daily from cholera.

DIPHTHERIA is prevalent in Chester county, Pa.

DR. MCGONIGAL, of New York, gets twelve years' sentence.

TYPHOID fever has broken out at Oley, Berks county, Pa.

DR. CLINTON COOK, of Chicago, has mysteriously disappeared.

THE Dunning Insane Asylum, Illinois, is to be lighted by electricity.

SOME unknown disease is said to be killing the oysters in the Chesapeake.

LASSAR, the Secretary of the Tenth Congress, is said to have become insane.

DR. PAVY has built and furnished a gymnasium for the use of the students of Guy's Hospital.

DR. PALMER M. KERN, formerly of Bath, more recently of Denver, Col., has settled in Easton.

THE Miners' Hospital at Hazleton has not passed out of the hands of the Building Committee as yet.

DR. HENRY ECROYD, of Philadelphia, is to be married to Miss Ashbridge, October 30, at Downingtown.

THE opposition to the extension of the Insane Department, Philadelphia Hospital, appears to have evaporated.

THE new Hahnemann hospital in Philadelphia was dedicated October 21. It has accommodations for 125 patients.

THE Norristown Insane Asylum has now in its wards over 1,800 patients, whereas it is designed to accommodate 1,300.

AN English justice has gotten into trouble by sentencing a man to five days' imprisonment for meningitis, of which he died in prison.

THE Trustees of Jefferson Medical College have requested Professor Bartholow to take a six months' vacation for the benefit of his health.

DR. J. W. PARKER, of Denver, shot Dr. Dameron, a dentist, on October 16, and slightly injured him. Should have loaded his gun with pills.

DR. F. H. WINES, of the Illinois State Board of Charities, is in Chicago, and will investigate the insane asylum and infirmary, which badly need it.

A NEW eclectic college has been organized at Indianapolis by members of that school who do not harmonize with the management of the old college.

DR. S. SOLIS COHEN has returned to Philadelphia from Dartmouth Medical College, where he has been giving a course of lectures upon therapeutics.

A NIGHT SCHOOL, which is free except for the charges, opened October 21 at the Central Christian Church, Twelfth street above Wallace, Philadelphia.

DR. BROWN-SÉQUARD has left the consideration of the elixir question long enough to recur to his query: "Does man have two brains or one?" The scientist resolutely ignores a certain order of individuals who belong to neither of these two classes, but are regrettably common in certain sections of the country.—*Chicago News.*

TENNESSEE has now in force an Examining Board, modeled on that of New York, containing regulars, homœopathists, and eclectics, Hydropaths, vitapaths, physio-medicals, and faith curists are not represented.

THAT wily man, Wile, is about to perpetrate on a long-suffering public a new medical journal, denominated *The Prescription*, and composed entirely of favorite formulas.

IT is said that the Marine Hospital Department contemplates having medical men attached to all United States Consulates, who will examine all persons desiring to emigrate to America, and ascertain their physical fitness.

IN San Francisco, Dr. Connelly has caused a young lady's arrest for "disturbing the peace." She lives on the floor above his office, and the ground of her offending is that, while she is an inveterate piano player, the physician denies that she is a musician.

CITY ELECTRICIAN BARRETT, of Chicago, has invented a means of working a draw-bridge by electricity. The main difficulty in the practical working of his plan is that as yet dynamos are not allowed to vote, while the owskis and offs can be depended upon in the primaries.

A REMARKABLE feat is recorded in the *Chicago Daily News* in the way of safe-opening. The burglar cut one of his nails down until the sensitive pulp was exposed. This he pressed against the knob, and turned until he could feel the tumblers drop into their places. After an hour's experimenting the safe doors swung open, and the ingenious rascal was nabbed by waiting detectives.

A DEATH occurred at Plymouth, England, during the administration of methylene. The lungs were found much congested; ventricles dilated; cardiac tissues soft and pale; kidneys large and congested; liver contracted. Methylene is administered in the Plymouth hospital about four hundred times annually, and it has been five years since a death under anæsthesia occurred.

AT the Philadelphia County Medical Society, on Wednesday, October 22, 1890, by invitation of the Board of Directors, Dr. J. B. Mattison, of Brooklyn, N. Y., read a paper entitled The Penal Status of Opium Habitués. Dr. John Aulde exhibited instruments and appliances for the administration of oxygen; Dr. Wm. Williams exhibited apparatus for sterilizing instrument and dressings.

ORGANIZED CHARITY.—The regular montly meeting of the Superintendents of the Society for Organizing Charity was held October 20, at 1705 Chestnut street, Dr. James W. Walk presiding. In the non-resident department sixty-four cases were disposed of; forty of these were sent to wayfarers lodges; eighteen did not report at lodges; six declined assistance offered; seven were referred to the St. George's Society, and two were granted transportation.

"LIQUID CRYSTALS."—A very remarkable paper has appeared in a recent number of Wiedemann's *Annalen*, on the subject of "Liquid Crystals." An industrious German chemist has, it appears, discovered some most curious organic liquids, drops of which, when examined in the microscope by polarized light, show definite axes of elasticity, just like crystals. That a liquid should possess an internal structure of this kind is one of the most remarkable of recent discoveries in the domain of molecular physics.—*Electrical Review.*

THE Governor of Sierra Leone is said to have reported that a number of American missionaries had died of tropical fever because, out of belief in the faith cure, they refused to avail themselves of medical treatment. The Governor further declared that "the climate of that country is not suited to those who trust to faith-healing and ignore the means placed at their disposal by Providence for the relief of suffering humanity."

The report is probably untrue; but, if verified, it should be made a serious question by those whose funds support the foreign missions, whether any good is to be expected from sending abroad as missionaries men who are devoid of common sense.

BLUE-GRASS ENDURANCE.—Professor N. Shaler, in his ethnographic researches, sought the record of a body of troops whose ancestors had been for many generations upon American soil, and he found it in the First Brigade of Kentucky troops (Confederate). In *Scribner's* for November he says: "On May 7, 1864, this brigade, then in the army of General Joseph Johnston, marched out of Dalton 1,140 strong, at the beginning of the great retreat upon Atlanta before the army of Sherman. In the subsequent hundred days, or until September 1, the brigade was almost continuously in action or on the march. In this period the men of the command received 1,860 death or hospital wounds, the dead counted as wounds, and but one wound being counted for each visitation of the hospital. At the end of this time there were less than 50 men who had not been wounded during the hundred days. There were 240 men left for duty, and less than ten men deserted. A search into the history of war-like exploits has failed to show me any endurance of the worst trials of war surpassing this."

INTERMENTS in Philadelphia, from October 11–18, 1890:

SOME time ago, when the *Index* gave the circulation of a number of prominent medical journals, the weekly TIMES AND REGISTER was quoted from Geo. P. Rowell & Co.'s newspaper directory as having more than 2,000 subscribers. The editor of the journal feels that an injustice has been done; and inasmuch as, at the time of consolidation of the periodicals constituting the now TIMES AND REGISTER the *Polyclinic* had about 2,000, the *Medical Times* 1,500, the *Medical Register* 2,500, and the *American Medical Digest* 3,000, the circulation of the present publication must be somewhere in the neighborhood of 9,000, instead of the 2,000 given—for which mistake the *Index* craves pardon, although it seems as if the error lies at the door of the publishers of the TIMES AND REGISTER. If a certified statement of the actual circulation of that periodical had been sent to Messrs. Geo. P. Rowell & Co., in response to the letter asking it, there is no doubt but proper circulation rating would have been given in the American Newspaper Directory. The inference that the publishers of the Directory would not give a satisfactory rating because the REGISTER failed to take advertising space is not a just one.—*Med. Index.*

[This is quite probably correct. The reflection on Messrs. Rowell & Co. was made hastily, and should not have been printed.]

SINCE the opening of the New York Pasteur Institute, on February 18, 1890, up to October 15, 610 persons, bitten by dogs or cats, came to be treated. These patients may be divided in two categories:

1. For 480 of these persons it was demonstrated that the animals which attacked them were not mad. Consequently the patients were sent back after having had their wounds attended, during the proper length of time, when it was necessary. *Four hundred patients of this series were consulted or treated gratis.*

2. In 130 cases the antihydrophobic treatment was applied, hydrophobia having been demonstrated by veterinary examination of the animals which inflicted bites, or by the inoculation in the laboratory, and in many cases by the death of some other persons or animals bitten by the same dogs. *All these persons are, to-day, enjoying good health. In 80 cases the patients received the treatment free of charge.*

The persons treated were:

64	from New York.	3	from Pennsylvania.	1	from Ohio.
12	" New Jersey.	2	" New Hampshire.	1	" Arizona.
12	" Massachusetts.	2	" Georgia.	1	" Iowa.
9	" Illinois.	2	" Texas.	1	" Nebraska.
8	" Connecticut.	1	" Maryland.	1	" Arkansas.
3	" Missouri.	1	" Maine.	1	" Louisiana.
3	" North Carolina.	1	" Kentucky.	1	" Ontario, (Can.)

THE Easton Hospital has been incorporated, a Board of Trustees and of Lady Managers elected. They have purchased a property on Wolf street, between Sixth and Seventh streets, which is now in the hands of the carpenters making the necessary changes, and will soon be ready for patients. The following staff has been appointed: Consulting Physicians, Drs. Traill Green, J. S. Hunt, and Isaac Ott; Attending Physicians, Drs. Charles Collmar, E. W. Evans, and H. D. Michler.

—*Lehigh Valley Med. Magazine.*

CHARITIES IN INDIANA.—The most interesting paper read before the State conference of charities was by Alexander Johnson, secretary of the State Board of Charities.

"We have in Indiana," said he, "besides county poor asylums, forty-five institutions of various kinds for the care and training of dependent children. The total number of children in these institutions is 2,723, and of these 1,518 are boys and 1,205 are girls, and of the total about 1,900 are receiving support from taxation. The sick, deaf and dumb, crippled, and infants under two years of age are not included in this summary. The total cost of these institutions in round numbers is about $175,000 annually. Comparing Indiana with other States we have one depen-

dent child in every 1,150 of population, New York one in every 300, Ohio one in every 837, California one in every 162, and Michigan one in every 7,000. The number seems to be increasing, for the homes are receiving children much more rapidly than they can find homes for them, although, with the exception of the Catholic orphanages, the placing-out plan is the one theoretically governing them.

"To this statement there are some marked exceptions. The Indianapolis Orphans' Asylum placed out last year a number exceeding fifty-five per cent. of its present population—not counting those returned to parents after temporary care. The Northern Indiana Orphans' Home placed out a number equal to two hundred per cent. of its present population."

—*Chicago Daily News.*

DR. WILLIAM A. EDWARDS, of San Diego, California, was married to Miss Frances L. Taft, on October 6. Dr. Edwards was one of a group of Philadelphia physicians, of a class far above the ordinary medical emigrant, driven to the West by premonitions of pulmonary disease. He, like Drs. Eskridge and the Haynes brothers, seems to have won the same high standing among his fellows of the Pacific slope that he enjoyed among the physicians of Philadelphia.

PATENTS, ETC., issued on medical subjects October 14, 1890:—

Catamenial-sack	G. Fuller	Gloversville, N. Y.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from October 3, 1890, to October 13, 1890.

BYRNE, CHARLES C., Lieutenant-Colonel and Surgeon, is relieved from duty as Attending Surgeon at the Soldiers' Home, near this city, and will report in person to the commanding officer, Fort Sam Houston, Texas, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Captain James A. Finley, Assistant-Surgeon, is relieved from duty at Fort Totten, N. Dak., and will report in person to the commanding officer, Jefferson Barracks, Mo., for duty at that station, relieving Captain William D. Crosby, Assistant-Surgeon. Captain Crosby, on being relieved by Captain Finley, will report in person to the commanding officer, Fort Pembina, N. Dak., for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Leave of absence for one month is granted Lieutenant-Colonel Joseph C. Bailey, Assistant Medical Purveyor, Medical Director of the Department. S. O. 86, par. 3, Department of Texas, October 3, 1890.

By direction of the Secretary of War, the leave of absence granted First Lieutenant Leonard Wood, Assistant-Surgeon, in Special Orders No. 74, August 30, 1890, Department of California, is extended one month. S. O. 232, par. 7, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Major Henry M. Cronkhite, Surgeon, is relieved from duty at Fort Lewis, Colo., and will report in person to the commanding officer, Fort Trumbull, Conn., for duty at that station, relieving Captain Robert J. Gibson, Assistant-Surgeon. Captain Gibson, on being relieved from duty by Major Cronkhite, will report in person to the commanding officer, Fort Sam Houston, Texas, for duty at that station. Par 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Major William H. Gardner, Surgeon, is relieved from duty at Washington Barracks, D. C., to take effect on the arrival of Major Joseph K. Corson, Surgeon, and will report in person to the commanding officer, Angel Island, Cal., for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Captain William E. Borden, Assistant-Surgeon, is relieved from duty at Fort Sam Houston, Texas, upon the arrival of Lieutenant-Colonel C. C. Byrne, Surgeon, and will report in person to the commanding officer, Fort Davis, Texas, for duty at that station, relieving Captain Peter R. Egan, Assistant-Surgeon. Captain Egan, on being relieved by Captain Borden, will report in person to the commanding officer, Fort Warren, Mass., for duty at that station, relieving Captain George McCreery, Assistant-Surgeon. Captain McCreery, on being relieved by Captain Egan, will report in person to the commanding officer, Fort Clark, Tex., for duty at that station, relieving Captain Charles M. Gandy, Assistant-Surgeon. Captain Gandy, on being relieved by Captain McCreery, will report in person to the commanding officer, Fort Shaw, Mont., for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Major Curtis E. Munn, Surgeon, is relieved from duty at Angel Island, Cal., and will report in person to the commanding officer, Fort Monroe, Va., for duty at that station, relieving Major John Brooke, Surgeon. Major Brooke, on being relieved by Major Munn, will report in person to the commanding officer, Fort Leavenworth, Kansas, for duty at that station, relieving Major Alfred A. Woodhull, Surgeon. Major Woodhull, on being relieved by Major Brooke, will report in person to the commanding officer, Fort Sherman, Idaho, for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

Clinical Lecture.

THE MODERN VIEW AS TO THE PATHOLOGY OF CANCER. SKIN GRAFTING.[1]

BY ERNEST LAPLACE, M.D.,

Professor of Pathology in the Medico Chirurgical College, Visiting Surgeon at the Philadelphia Hospital, etc.

GENTLEMEN: Later in my hour I propose to operate upon two cases; the first, the skin-grafting, according to Thiersch's method, of two rather extensive ulcers of the leg; the other, the removal of a number of venereal warts from the penis of a young man who has been a sufferer from gonorrhœa. But before speaking of these cases I thought I would take this opportunity to address you upon a question of vital importance in surgical pathology, and endeavor to reduced to a nutshell, and to make tangible to you, the chief points in the modern view of the pathology of cancer; cancer, the thing of such dread to those afflicted with it, and likewise to us who are called upon to treat it; cancer, the bugbear of the medical student who must make a diagnosis between it and sarcoma.

The word cancer means simply crab, and on account of its eating and gnawing property it was given this name by the ancient pathologists. The later pathologists have discovered the true nature of cancer, which is nothing else than an hyperplasia, an exaggerated development of cells, a growth in a particular part. This growth may exist on the surface and bulge outward, or existing on the surface it may dip into the tissues; and according as the growth takes one or the other of these directions, so will the growth be benign or malignant.

The simplest of all growths is growth upon the surface, an epithelioma. No doubt you have all been out rowing and have had callous spots upon your hands following upon a blister. These are due to an irritation of the cells of the skin of the palm, which is followed by their proliferation and growth, and the production of a benign epithelial tumor upon the spot. On the other hand a man is a smoker; he smokes a pipe which presses always upon the same spot; but, mark you, the man comes from a family of cancerous ancestors. He has the cancerous soil in him, and only wants the chance to develop the cancer. Perhaps a slight scratch or abrasion exists upon his lip, and this is irritated by the pipe. A congestion, an hyperæmia follows, a cell proliferation occurs, and, then, as we have every reason to believe, a specific micro-organism is deposited upon the inflamed spot, and an epithelioma is developed with a growth inward, and an infiltration of cells into the tissues, whereas, in the first case, there was only an accumulation of cells.

The true epithelioma, if we wish to be scientific, is any growth of epithelium, and this would include the corn and the callous spot. But this is not the general acceptation of the term. In order to develop a cancer the cancerous diathesis must be present, which, although we do not know precisely what it is, we do know that it is some chemical change in the system which gives rise to the tendency to the formation and growth of cancerous products. The chemical decomposition thus produced gives rise to the products known as ptomaines. So much for the epithelioma, but this leaves out of consideration a whole class of cancerous affections. No matter where the growth exists the process is identical. So we now come to consider that class of growths that is characterized not by epithelial, but by fibrous tissue, the class including fibromas, sarcomas and scirrhus cancers.

Gentlemen, the processes of nature are blind; she acts as she is forced to act. When we have an amputation, and the large flaps are open, and a dreadful gash has been made, the surgeon sews up the wound and trusts to nature to heal it, and all the elements

[1] Delivered at the Philadelphia Hospital.

that are necessary to the growth of the most malignant of cancers enter into the kind healing of that wound. The wound is closed by the surgeon, but the knife in passing the tissues has produced an irritation, and a congestion results. A clot forms at the end of the several blood-vessels, thus stopping the hemorrhage. But the heart is working behind, and the blood still comes into the vessel, and here and there we can see the white blood corpuscles, which pass through the stomata in the dilated blood-vessels by a process of hour-glass contraction. This phenomenon, you know, is called "diapedesis," and these exuded corpuscles are called "leucocytes." These leucocytes are destined by nature to grow into fibrous tissue, which they do by elongating more and more until they take the shape of a fiber. When millions of these white blood corpuscles have exuded we say that the wound is covered with healthy granulations, which fill up the whole wound. When those on the surface are formed, the lower ones are about two weeks old, and have passed through successive stages from round cells to spindle cells, and finally to fibrous cells, and the wound is closed up by fibrous or true cicatricial tissue. The next step is a sealing of the wound with epithelium, and the process of healing is completed. Should these leucocytes be killed, they would manifest their death by undergoing the fatty change we call "pus."

You must retain these steps closely in mind if you wish to have the least notion as to the growth of cancers. All growths include only fibrous and epithelial tissues, arranged, however, in different ways. Now, as regards sarcomas. Just as epitheliomas are due to the development of epithelial cells, the fibroma is due to the development of fibrous cells, and the sarcoma is only a variety of fibroma. If the blood vessel which is cut is subjected to any irritation, congestion will occur, with diapedesis. This will finally result in the formation of fibrous tissue. Now, if you make a section through a sarcoma, you will observe a variety of cells. If you make the section through the youngest growing part, the cells will be found to be all round, and you would call it a "round-celled sarcoma." If through the older portions, the cells will be found to be all spindle shaped, and you would call it a "spindle-celled sarcoma." If the tumor has been of a very slow growth, you will find only fibrous cells, and you would call it a "fibroma." So a fibroma and a sarcoma are the same thing, only that the old sarcomata are more rapid in growth than the simple fibromata. All must pass through the same process of development.

Now for the true carcinoma, or, in other words, the development of a cancer inside of a gland. A true cancer may be either soft or encephaloid, or hard or scirrhus. When the endothelial cells of a gland are attacked by an irritant they proliferate and produce the soft growth called "encephaloid," because it resembles the brain in consistency, which the ancients called "encephalon." A scirrhus is nothing else than a combination of the encephaloid with a fibroma, where the fibers of the latter, possessing contractile power, secure the ascendency, and produce a hardness of the growth. Under the microscope we can see these fibers all around, and within them the true epithelioma packed in the meshes.

Now what about the mucoid degeneration and amyloid cancers? Gentlemen, what I have told you is all that nature will do; but in doing this, these cells frequently die, or are squeezed to death by the contracting fibers, and undergo degeneration into calcareous, mucoid, or amyloid material. A word as regards metastasis. To my mind, the very best proof of a malignant growth being due to a micro organism is this element of metastasis. If, in removing a cancer, all is not removed, there will be a redevelopment of the growth. One germ is all that is required to produce a new formation. The poison travels through the lymphatics to the neighboring glands and develop there a like growth. Finally, here is a suggestion which I hope will take away from you any stereotyped idea you may have as to when to pronounce a tumor malignant or benign. The callosity is a benign growth because the irritant which produces it is outside of the body and can be removed. The cancer is a malignant growth because the irritant is within the body, and we cannot always remove it entirely.

There is one more growth I wish to mention, and that is the lipoma, with its relation to malignant growths. A lipoma consists of fatty tissue, with here and there fibrous tissue. A lipoma, then, is nothing else but a genuine fibroma, in some of whose cells fat has been deposited, the oil pushing the nuclei to one side. Finally, why are fibromas not as malignant as genuine cancers? Because the fibrous cell has not the power of infiltration as has the epithelial cell. Here, now, is a man who had an epithelioma of the penis, and the organ was removed twelve months ago. He comes back now in this condition, with the growth in his groin. The point I wish to call your especial attention to is this: Were I to cut into this tumor and remove a portion of the hypertrophied gland, and send it to the microscopist, the report would undoubtedly be "a most malignant epithelial growth," because he would find epithelial cells with no structure—an encephaloid. But if I move further to the side, and cut off a little of the hypertrophied skin, the report would be, "a most malignant epithelioma," because he would recognize the tissues of the skin with an infiltration of epithelial cells. Furthermore, if I were to cut further outside of the growth, the report would be, "a true sarcoma," because the epithelial layer would not be affected, but only the fibrous connective tissue, with a great hyperplasia, consisting of fibrous cells in various stages of development.

This man presents two ordinary, large ulcers of the leg. He has been treated as well as he could be by sterilization with acid sublimate solution. Now, having a good, healthy substratum, I propose to supply the skin by taking some from his thigh and placing it upon the ulcers. I shall follow, in doing this, Thiersch's method. Reverdin's method consists in taking a small piece of skin and placing it in the center of the ulcer. Thiersch thought that if a small piece of epithelium would act well, perhaps a larger piece would do better, and he put this into operation with success. The skin should be placed evenly over the wound, and the whole covered with a sterilized dressing.

THE managers of the Maternity Hospital have been obliged to issue a fresh appeal for funds, as their treasury is almost empty, while the demands upon them for help are great and imperative. This hospital is managed on liberal principles, which entitle it to special consideration from the generous minded. It not only ministers to the bodily wants of its patients, but helps to save some among them from despair and crime. But it is without funds, and depends for its maintenance upon the contributions of the public. The Treasurer is Mr. William H. Ingham, No. 308 Walnut street.

SEROUS CYSTS AND CYSTIC FORMATIONS; ABDOMINO PELVIC.[1]

By THOMAS H. MANLEY, M.D.,
NEW YORK.

CYSTS and cystic formations, in every degree of development, being of very frequent occurrence in that cavity roofed above by the diaphragm, I shall select that entire district for study, below the thoracic arch; bounded laterally by the parietal muscles of the abdomen; anteriorly by the median line, the central recti, the ensiform cartilage, and pubic symphysis; posteriorly by the spine and the powerful dorsal muscles, which play in either of its lateral grooves; the abdomino-pelvic cavity, which in the female encloses all the organs of generation, and, in both sexes, the whole digestive apparatus, except two short segments, at either extremity.

Since the advent of modern innovations, which have made it possible to study the elementary nature of neoplastic formations, and to treat them successfully with the aids which scientific investigations have placed within our reach, it is interesting to consider in what they consist, and estimate their practical application, as far as they concern serous cysts and cystic formations. In the present instance there is no pretence to enter *in extenso* into an elaborate or tedious survey of the prodigious strides made in the way of dealing with intra-abdominal cystic disease during the past twenty years, or examine into the validity of the almost endless theories regarding its primary cause. My object will be rather to direct attention to a few features, in connection with this study, which seem to be of some interest, and, perhaps, a little practical value.

THE NATURAL HISTORY OF SEROUS CYSTS.

What is the essence of cystic disease? Have those liquid cysts an independent existence, and do they possess within themselves the power to reproduce and multiply their like? Have they a life limit; advancing to a certain stage of development, and then manifesting retrogressive changes?

A serous cyst is a structure of a low grade of development; because it does not, under ordinary circumstances, produce mixed elements, and it maintains to the end, when unincumbered by pathological changes, its original histological structure. Consisting, anatomically, of an investing envelope, which is composed of cellular elements with more or less numerous nucleated strands of fibrous tissue, it becomes eliminated only by age or inflammatory changes. Internally lined by endothelial cells, which have the property of both increasing or diminishing the quantity of the enclosed liquid. Externally, as it leaves its primitive nidus, it lifts up, and invests itself with a duplicature of peritoneum.

The liquid contents, although designated serous, possess no properties in common with the serum of the blood, except in physical character, and are generally of a low specific gravity; of an alkaline reaction; bland and unirritating.

They sometimes are found with a narrow, pedimentated base, but more often they have, along with an extensive attachment from beneath, several collateral adhesions.

We have monocystic and polycystic growths; the former being the most common; with the latter we may find, springing up from the center, one very large parent cyst; about the root or stalk of which there arise, like so many buds or offshoots, several others of varying sizes. There are not infrequently clusters or groups of these daughter cysts studded over the outer surface. What is, perhaps, most frequent, they form internally, in bunches, and fuse together, when the neoplasm is designated multilocular.

That cystic tumors may undergo, in the process of time, myomatous, colloid, fatty or puruloid changes, is now an unquestioned fact.

How those cysts originally come into existence is yet unknown. There has been much speculation on this subject; but no theory has yet been constructed which will satisfactorily account for them. The latest view is, that they arise from anatomical or corpuscular elements, which, in intra-uterine life, wandered away from their normal habitat, and were not absorbed or assimilated, but, in the progress of time, under favorable influences, asserted their individuality, or aggregated together, and made their existence manifest under divers forms.

Another, later, and more plausible view is, that they have their origin in unabsorbed fœtal remnants, in the female, from the Wolffian corpuscles and the rudimentary Graaffian vesicle.

This latter view, however, has no substantial logical support, and is opposed by facts which render it utterly nugatory; among which may be mentioned the fact that the fœtus *in utero* itself may be the subject of such extensive cystic growths, within its abdomen, as to render delivery by the natural passages impossible. Further: why should there be but isolated cases of serous cysts, arising from stray corpuscles, when those so-called fœtal remains can be demonstrated microscopically within the basic substance of the broad ligament, and in the reticulated structure of the ovary, in nearly every subject?

Lastly, although those who maintained the theory of primitive, ante-natal origin have specially selected the male and female genitals, as the parts in which the work of evolution is retarded or deranged, yet, as a matter of fact, serous cysts may be found in any structure within the abdomen, invested by the peritoneum.

They possess most active regenerative power; hence, when extirpated, they frequently reappear, regardless of whether any portion of the matrix is left or not; and, if not springing up in the same locality, they may elsewhere; when we say, the person has a predisposition to cystic disease.

That they have a life limit and are independent entities, I am strongly convinced. In the whole range of creation the expanse of life has confining lines; hence, judging from analogy and from the frequency of cystic disease, found *post-mortem* with those who in life were unconscious of its existence, we may assume that, as a rule, they reach certain stages of development, when they cease to grow and fade from sight.

From many conclusions arrived at only after careful reasoning, I am convinced that like the hepatic or cerebral cyst of echinococci, depending on the liver-fluke for its existence, these serous cysts have their origin from an undiscovered microbe which gains entry by way of the ærian or alimentary passages, and that when this germ finds suitable soil, or the system is in a receptive state, it rapidly develops.

A serous cyst is parasitical; fastening itself on and drawing its sustenance from wherever it may commence its growth.

[1] Read before the New York Medical Association, October 22, 1890, in New York.

These formations are essentially degenerative in their character, and though they grow and thrive under most diverse circumstances, yet it can be scarcely said that one is in perfect health who has borne them in large numbers, or of considerable size.

Against the doctrine of extraneous or extrinsic origin, it may be alleged that we may find those tumors when direct infection would seem impossible; as when we encounter them congenitally. And, besides, because nothing has been discovered by microscopists which would tend to support this hypothesis.

All must admit, however, that they are excrescences, and have very many features presumptive of independent organization; and that their presence in the brain of the fœtus is conclusive proof that the microbe or offending agent may enter through the circulation.

That the infinitesimal elements which may go to originate these cysts have so far eluded the microscopist no one need wonder at, as their study, in the direction of pathology, though so far of singular partiality, yet is but in its infancy.

ETIOLOGY.

With the microbian doctrine as a fundamental basis to start on, the causation of these growths under consideration is greatly simplified, and their nature better understood. Without it, as we are to-day, the etiology of serous cysts may be written in one line: We absolutely know nothing whatever about it. We are rich in speculation and theory on the subject; in fact, however, we are in total ignorance. Why, indeed, that we should usually go to advanced age before these cysts appear; why one brother is attacked, and another free, or why women are most subject to them, we do not know.

But there are many phases of these developments, with which it is highly important that we should familiarize ourselves, particularly in relation to their natural history.

As this parasitic formation may be regarded, as a rule, as a process of degeneration, we meet it very frequently in the aged female, on the periphery or in the stroma of the ovary, about the kidney and other situations. In forty-three post mortem examinations in my service at the New York almshouse hospital, on women past sixty, thirty had cystic disease in the ovary; some on one side only, but a large proportion on both.

Age then must be regarded as a predisposing cause. Sex: The female, by all odds, is the greatest sufferer from ventral or pelvic tumors. Maidens, barren wives, or women who deliberately diminish childbirth are more prone to cystic disease than good breeders who bear large families. At the climacteric, the menopause, the third epoch of woman's existence, these tumors are most disposed to make their existence known.

Sex makes its impress felt in the organs most susceptible to the disease under consideration. The uterus and its adnexa are the favorite areas of selection in the one; while with males the renal tissues, the supra-renals, the lumbar, sacral, omental, and mesenteric elements seem specially susceptible to encysted dropsies, or what is commonly known as encysted peritonitis.

There can be no question, in my mind, but many of these so-called abdominal dropsies—ascites—in which there may be a large, but quite symmetrical, accumulation of liquid; and wherein there is an absence of evidence of organic disease, and medicines make no impression, but one free tapping promptly cures the patient permanently, the medical attendant may mistake a local condition for organic disease, and he may simply drain a cyst without entering the peritoneal cavity at all. There seemed to come such a case under my observation not long since. It teaches a most practical lesson, and, though my diagnosis was lacking the confirmation of post mortem examinations, yet I scarcely think a mistake was made.

A young man of twenty-three years had been ailing at home, of some obscure abdominal disease which resisted medical treatment. As his funds ran low and he was advised that a hospital was the proper place for him, he entered one of our principal institutions, where he was purged, blistered and starved—put on milk diet; but his belly became larger and harder; his urine icteric and scant; and, owing to his stomach being crowded back against his spine, though he was hungry, anything entering it added to his discomfort. His distress for breath was so great that he did not venture to lie down for fear of smothering, and hence what snatches of sleep he got were taken in the sitting posture. Making no improvement in hospital, his parents took him home.

From the history that I got, I was not so sure about his condition being wholly attributable to organic disease. He suffered from pain, sometimes before the swelling appeared, and the fullness was said to have risen in the epigastrium and descended towards the pubes. Besides, on physical examination of his abdomen, which was greatly distended in the left hypochondriac region, low down, the tympanitic note elicited indicated the bowel lying against the abdominal wall, and not away from it. No change in posture altered this; hence, taking everything together, I ventured to assure the parents that I could very quickly give him a chance for his life, and probably cure him. To make certain, I passed in an exploratory needle, but superficially, and was rather chagrined to find a fluid with all the characteristics of ascites. Passing it in again deeply, in the opposite flank, where the swelling distinctly but slightly bulged, I withdrew a watery liquid wholly unlike the former.

Taking each away in a separate vial, I examined them, and found one bile-stained serum, and the other opalescent in color, of a low specific gravity, with no cell detritus, and of such composition as we commonly find in ordinary cysts. I was now satisfied that the ascitic fluid was secondary, and the bile-tinge was due to an impediment of the gall-flow, a retention. On examining the urine, I found it highly albuminous. Both lower extremities were in an anasarcous state. As a free incision was not permitted, after due antiseptic precautions I thrust a large trocar into the most prominent and resistant part of the abdomen, low down, near the median line, in the left iliac region. Something more than two gallons of cystic fluid escaped. I then twisted into the puncture a strand of silk for drainage.

This young man rapidly and completely recovered. All his organic ailments were solely attributable to pressure, which, when removed, not only gave immediate relief, but was quickly followed by full unrestrained functional and organic action.

Had his condition been as presumed, and as treated for, the evacuation would have been followed by a refilling, and the organic disease would have remained.

Although cystic-disease seems to manifest a special predilection for the female genitalia in early life, with the male it is more common in advanced age, in the external genitals, in the form of spermatocele, simple and encysted, and as hydrops vaginalis. Renal

cysts, too, are more common in the male, and also make their appearance late in life.

The intimate sympathy between the generative and urinary organs is a matter of common observation. In kidney disease sexual desire is usually in abeyance, while in consumption the power of procreation remains to the last. With the female, this association is not so evident, nor is parenchymatous or calculous disease of the kidney as common with them; however, it is seldom that there is any wide deviation in generative function with them that there is not a responsive renal manifestation. The frequent coincidence of nephritis, albuminuria, or even total suppression of the urine, in pregnant women is often witnessed.

So that, I think, inasmuch as serous cysts are seldom seen, except in the reproductive and urinary organs, their origin and growth often may be regarded as in some manner as yet inexplicable connected with their functional derangements. I have met with two cases of abdominal cysts which might be traced to traumatisms.

The relation between cause and effect here is not very clear under those circumstances, hence the only explanation I can offer, is that the nucleus, or germ, was present in a dormant state, and was roused into active growth by the vascular engorgement, co-incident with the incipient inflammatory state, following the injury. This is often the history of cancer, and, I think, will occasionally apply to benign growth as well.

THE MORBID ANATOMY AND PHYSICAL CHARACTERS OF SEROUS CYSTS.

Before an attempt is made to discuss the pathological changes and morbid conditions resulting from serous cysts, which compromise health, or endanger life, we must have a clear understanding of the regional anatomy of the abdomen; its guides and landmarks. Probably for general purposes the arrangement of Treves (Applied Anatomy) is as useful as any; but for surgical purposes I prefer the plan of Hewitt and H. Marion Sims (Abdominal Tumors, etc.), according to which a horizontal plane passing through the tenth rib on either side is the epigastric region; the lateral portions of which are the hypochondriac regions. The umbilical region is bounded by the lower limit of the epigastric region, and below by a line passing between the anterior superior spines of the iliac bones, on either sides. The hypogastric region includes that portion situated below the line last named; the inferior boundaries of which are the ossa puberes and ligament of Poupart.

It can be readily perceived that after a large cyst of deep origin has gradually advanced toward the surface, pressing aside, crowding beneath, or ballooning up the solid and hollow viscera, gluing them together, twisting and compressing them into every conceivable shape and direction, the normal lines, curves, angles, and grooves of descriptive anatomy have but little practical application; hence, when an operation is undertaken, the operator must not only be familiar with the undisturbed arrangement of health, and also the changed appearance with respect to color and visible characters, but he must also employ his sense of touch, which is the most valuable of adjuvants in the physical diagnosis of the abdomen. The ear and nose, too, must be trained to assist in emphasizing and interpreting the confused and embarrassing condition often present.

To meet these requirements a practical knowledge of morbid anatomy and applied physics must be attained. The cyst coming in its primitive stages from a microscopical corpuscle assumes every diversity of form and outline; spherical, oblong, flat, conical, branched, serpentine, and many others, according to the quality and direction of the resistance which it encounters.

The enormous distending power of the imprisoned liquid of those sacs, I must acknowledge, is, to me, quite incomprehensible. There certainly is no principle in hydraulics to explain it, as far as I can learn. A concentrated pressure to the square inch, which will put the cystic wall in such an extreme, resisting tension as to give it the hard, stony feel of a compact scirrhus growth, and deceive the touch of a trained diagnostician, one would think must choke off every sort of circulation in the vessels which nourish it.

The walls of a barren cyst are of varied density, but never very thick. The tumor remains pedunculated, until, by friction or weight, it chafes the neighboring parts, when plastic inflammation binds it to them. Now, as it swells in volume, or changes its direction, it drags along with it those movable viscera, with which it is firmly bound, and we begin to notice these symptoms, or warnings of the economy, that a tubular structure, or important organ, is becoming compromised; and if we are not guarded, and fail to examine critically into the case, we may attribute the condition as dependent on constitutional and not local influences.

The histological, or minute anatomical, cells of those cysts occasionally take on many changes, both in their chemical composition and morphological elements. They are dependent on variation in the vascular supply, on inflammation, and inoculations peculiar to all neoplastic bodies as age advances.

Besides, it is fair to presume that many of them, particularly in the female, undergo spontaneous rupture, or give way to sudden pressure or strains, and are wholly absorbed.

Along with atrophic changes we may have those dependent on increased vascular action, accompanied with a diapedesis or transudate of leucocytes and coagulable lymph; which adds to their former translucent color a flocculent turbid material, giving the cysts contents the appearance of genuine pus. The watery elements of a cyst occasionally assume a gelatinous consistence, or when the smaller capillaries rupture, blood is blended with their alkaline contents, which gives them a dark pigmented appearance. When many cysts fuse together we have the polycystic, or multilocular tumor, which is seldom seen, however, except in the female, and attains vast dimensions. This growth is composed of most complex elements, and as it clearly belongs to the proliferating, more highly developed new growths, it will not be considered here. Cystic disease within the abdomen is said to be intra-peritoneal and extra-peritoneal.

Neither assumption do I regard as quite correct. Every so-called intra-peritoneal cyst has a peritoneal investment, except at its stem, where it comes up from the areolar tissues. The retro-peritoneal, or extra peritoneal — among which are classed the renal and lumbar cysts—originate in or about the serous glands of the pelvic-fascia, and invariably have a peritoneal investment. But there is this important anatomical difference in the situation of the two, viz.: that one can be reached and drained without in any way involving the serous membrane; while in the other, the peritoneal cavity must be always opened.

Cystic disease may arise simultaneously with cystic formations. This association may lead to great difficulty in diagnosis, and unfortunate results in treatment. No nook, passage, or tract on the surface, or within the many complex and intricate folds of the peritoneum, but may be the seat of cystic growths. Hence, when they arise in close proximity, or in connection with various organs, their presence may be mistaken for other pathological conditions, if this fact is not constantly borne in mind.

CLINICAL HISTORY AND DIAGNOSIS.

The subjects of cystic disease are seldom afflicted with pain, until the tumor, by *its* size or location, presses on a nerve, induces obstruction, or excites inflammatory action. Many may carry them a life-time, unconscious of their existence.

Yet it is a rule, that in a person with extensive cystic disease, there is a want of *embonpoint;* physical vigor is diminished; the nutritive processes are defective in action, and bodily strength is greatly impaired.

The patient, often long before the cyst has been suspected, and even when of small size, will complain of deep seated fugitive pains; at one time intense, and at another of none at all. The appetite fails, and comfort is best secured by rest in the recumbent posture. If these growths occur in the female, at each monthly flux there will be an aggravation of symptoms. I have noticed in every case which I have yet seen, that the skin has a clayey, tawny color, not unlike the cachectic tint of malignant disease.

The location, extent of distress, and constitutional disturbances, depend on a multiplicity of factors. In one but slight inconvenience is borne, while in another life is tortured with racking pains; patience, fortitude and hope fail, and the stoutest, most vigorous and energetic, give way and succumb.

The symptoms, those dependent on vascular, neural or inflammatory changes, will accentuate themselves in proportion and character according to the organ or structure involved. They arise primarily from two causes chiefly, from pressure and inflammatory action.

By tension, strain, or weight on important nerves or their filaments, pain localized, diffused, and reflex arises. The intimate intermingling, or close association of the branches of the genito-crural, lumbo-sacral and the external pudic nerves, give rise to a most embarrassing association of symptoms, when serous cysts of small size but of firm consistence develop along their course.

In the female, under these conditions, the pain may be referable to the ovary, uterus, ureter, kidney or the deep structures along the pelvic floor; hence, its clinical significance, when taken alone, is of little value. The size of the tumor may not always occasion so much inconvenience or interfere with functional activity, as one of minor dimensions which has contracted extensive adhesions, and will not permit of the free play and the unrestrained movements so necessary to the varying capacity and shifting relations of the abdominal viscera.

Among the many pathological phases of structural and organic implication witnessed in the progress of development, we may mention a few of the greatest practical import:

The first and most destructive is that in which by weight or tension, the contents, circulating or occupying a tubular organ, are impeded or wholly arrested. When the larger trunk of an emulgent vessel is obstructed we will have œdema of the limb, a turgescent state of the blood-vessels, and peripheral congestion. Symptoms attributable to compression of the vesical outlet of the bladder or the rectum cannot be misconstrued. It is only when the cystic walls occupy a wide spread area, and commence to encroach on the blood-trunks of the chylopoietic organs, the portal system of vessels, the hepatic and renal viscera and their excretory ducts that we are warned of the serious inroads on health which a serous cyst may originate. Of the solid viscera within the abdomen the kidney seems to suffer most. Lying in close apposition to the spinal column it comes in for a large share of compression when the growth presses from before backward. Its long excretory duct, passing downward behind the peritoneum, and over the sharp edge of the pelvic rim, is greatly exposed to occlusion, both by tumor pressure and obliteration of its lumen as a result of excessive plastic exudation.

Accordingly, in those instances in which we have associated a renal cystic formation from a urinary back flow, and enormous distension of the renal pelvis with a common non-proliferating serous sac, it would appear that the secondary difficulty occurred by the cyst in some way pressing aside, hoisting, or closing the ureter, when the enlargement within the renal capsule followed.

This view is strongly sustained, too, by certain unequivocal chemical phenomena. As, for instance, when the patient first complains of the deep-seated pain along the loins, in the back, or pelvis, there is no diminution in the quantity of urine voided, or variation in its chemical or physical composition, we know the gland is not involved. But, on the other hand, when contemporaneously with the now visible swell made prominent by the serous fluid crowding a cyst outside the quadratus lumborum muscle in the direction of the least resistance, or if the serum gravitate into and behind the loose sacral fascia, lifting up any pelvic cyst which may lie in its way, we are soon made aware of serious renal complications, by symptoms of suppression, auto-intoxication, and marked constitutional derangement.

As *renal* cysts, liquid encapsulated growths, are more common in the male sex, arising in the loose cellular tissues in which the kidney is lodged; when a man much past the meridian of life complains of deep-seated pain high in the loins with no evident kidney disease, particularly if there be a localized, movable fullness, we should examine cautiously, and make a diligent search for a neoplastic growth of the serous genus, for no hygienic measures or constitutional remedies will avail to give relief, and valuable time will be lost by temporizing expedients.

When we reflect what a complex anatomical structure the lymph-sac of the abdomen is, with its manifold reflexions and duplicatures, and remember that anywhere within its laminæ those serous cysts may rise, we may form an idea of the number of organs in immediate contact, and even remote, which either primarily or secondarily suffer functionally or structurally in encysted dropsies within the abdomen. We may also contemplate, if we cannot interpret, the almost infinite group of symptoms.

The serous lining of the abdomen possesses two qualities prëeminently peculiar to itself.

Along with its wonderful power in absorption, it will respond to the slightest irritation by plastic inflammation.

Now, when the growth of a liquid tumor is gradual, and it spreads among the movable viscera, it

may, in the female, occupy a very wide-spread area without embarrassment to the respiratory act, as, with her, breathing is almost wholly thoracic. With the masculine sex, on the contrary, when free movement of the diaphragm is paralyzed, death is imminent from suffocation, so that by this mechanical impediment—a voluminous tumor—alone, life may be sacrificed. The peritoneal surface is tolerant to the intrusion of a neoplastic tenant, when it spreads evenly and develops slowly; but in time it will restrict its movements and unite with it by adhesive inflammation.

It is, no doubt, at this stage that the patient becomes, for the first time, conscious that there is some thing wrong, as indicated by localized pain of a persistent character.

Ordinarily, the peritoneum and the subserous cellular tissue are quite destitute of sensation; but when inflamed it is exquisitely sensitive, and is the seat of pain, which, if unrelieved, often is quickly fatal.

Those peritoneal tumors which spring up from the pelvis, and mainly occupy the hypogastric region or either flank, or those originally sprouting from some minute element within the epiploon or mesentery, but are within the peritoneal cavity, are not attended with so much difficulty in diagnosis as that variety known as encysted peritonitis, or those which continually take a course under the retro-peritoneal tissues.

The latter, lying behind the peritoneum, attaining vast proportions, and ballooning up the intestines in their march towards the pelvis, are extremely difficult of recognition, and may be confounded with ectopic pregnancy, local hemorrhages, phlegmonous disease, or ovarian tumors.

They generally may, however, be recognized by the clinical history and physical diagnosis.

Effusions into the broad ligament, or growths developing within it or the ovary, commonly lie in contact with the parietal peritoneum, *anterior* to the hollow viscera; while with retro-peritoneal cysts, or those rising in the lumbar renal or the mesenteric glands, the bowel lies *in front;* and while the patient has, perchance, an enormous dropsical effusion within the abdominal walls, with embarrassing respiration, inducing distraint in the circulatory and secretory organs, yet the peritoneal cavity is not involved; in fact, the sac, with its inclosed viscera, is lifted *en masse* and tossed about in a most distorted shape, like a sort of float, while the loose pelvic tissue and lumbar fascia are stretched from their attachment by the enormous liquid accumulation.

In a case coming under my care, of this description, this last summer, the patient suffered most terribly. His bowels and bladder annoyed him exceedingly while hungry, yet the admission of food into the stomach gave him additional distress, and he was not quite at ease till he vomited. So labored was his breathing that sleep in the recumbent posture was impossible.

Pain in the back, the loins, down the course of the anterior crural nerves, and up, over the pericardia, distressed him unceasingly. The lower limbs and the scrotum were greatly swollen, as in the preceding case, by œdema, and even over the sacrum, the thumb would leave a deep depression.

In his case two well-known consultants had failed to make a correct diagnosis. One would have it cancer of the kidney, the other set it down as cirrhosis of the liver, with ascites. It is needless to say that they gave no hope of recovery, as well they might had their opinions been correct.

A minute and detailed description of the differential diagnosis of those serous cysts growing only from the female reproductive organs cannot be undertaken, on this occasion, for it is a subject which strictly belongs to the specialist in women's diseases, many of whose valuable monographs and treatises can be had in any medical library. It is evident, then, under many circumstances, that one may confound cause with effect; that skilful physicians, from over-confidence in their ability, or undue haste in examination, may attribute certain signs to organic disease within the abdomen, when the real difficulty is wholly external, or in a part in no connection with it, but is all the result of hydraulic pressure spread from cysts.

CYSTIC FORMATIONS.

Everything not originally arising from a microscopical element, of a liquid nature, which is encapsulated, may be regarded as a cystic formation, although Sir James Paget excludes the products of inflammation—as abscesses, or pus accumulations, and hematomata — from the category of cysts. They are mainly attributable to blocking of the tubular passages of exit for the gland yield.

The ureter is obstructed, either by a calculus, a narrowing of its lumen, from inflammatory channels within, or malignant disease from without. The ureter bursting, the escaping urine dripping into the peritoneal cavity is often encysted, until the rent is healed or the impediment removed.

This obstruction of the urine is hydronephrosis, and becomes pyonephrosis when the cysts' contents take on purulent changes, either before or subsequent to the artificial evacuation of the liquid. Of forty-three recent cases of hydronephrosis which I have collected, twenty nine, or nearly two-thirds, were on the right side, and of them twenty-six were in men.

As the cæcum, the gall-bladder, the orifice of the pancreatic duct lie on the right of the median plane, we must expect to find every sort of enlargement here, or adventitious formation, more numerous than on the left side.

Impediment to the free passage of a gland's secretion depends on conditions which originate within itself, and those which operate through disease of adjacent parts.

Biliary and renal concretions, when large, and not acted on by the bile or urine, are occasionally impacted in the duct. Malignant disease, infiltrating in every direction, will seldom, when in proximity to the kidney or liver, embrace or wholly occlude their drain-vents. In fact, a new growth of any kind may crowd them aside and close them. When the opposite kidney is healthy, and the back-flow is recent or of small quantity, beyond some slight, local disturbance no marked impression is made on the constitution. But when the renal pelvis expands, the hydronephrotic fluid increases in volume; the systemic circulation becomes impregnated by absorption, the urine is diminished in quantity, and highly albuminous, and the time has arrived for prompt surgical interference. A hydronephrotic cyst is of more rapid development than a simple cyst, and from the history, with the direction which the accumulation takes, it may generally be recognized. However, if there is much doubt, the exploratory-needle is an infallible test. The chemical examination of the quantity withdrawn will decide the question. As the encapsulated urine is always behind the peritoneum, the needle entering posteriorly is *outside* the peritoneal cavity. Certainly there are many pathological conditions in which the use of the exploratory-needle is interdicted, as it is only when the enlargement is

of a fluid character, and we are quite certain it is extra-peritoneal, that we may adopt this expedient with safety and advantage.

We can scarcely confound a hydronephrosis with other allied conditions; provided the state of the patient be thoroughly investigated, and we keep our patient under observation an ample length of time to enable us to come to a correct diagnosis by exclusion. A visceral, cancerous growth is attended with little pain. But when imbedded in the loose tissues of the loin, it may present characters of a kind which will puzzle the most wary and shrewd diagnostician.

The kidney itself occasionally takes on parenchymatous changes of a sarcomatous nature, which will greatly swell its volume and cause displacement. Pus accumulation, or hemorrhagic extravasations, in the iliac-fossa, when the clinical features of each is considered, will not probably mislead.

Happily, simultaneous, or double hydronephrosis, is never met with; at least, in scanning the English and French literature on renal pathology, I find no well authenticated case of such a complication. Hydronephrosis may have various terminations, when art does not interfere. If the ureter is clogged by a blood-clot, a mass of fibrinous lymph, or a small calculus, as soon as it disintegrates the canal is reopened, the swelling collapses, and the symptoms suddenly vanish.

In the event of a thrombus or impediment remaining, the pressure on the renal artery will reduce the blood supply, and gradually produce an interstitial absorption of the secreting structures of the kidney, so that in time, as the gland finally yields up its existence and wholly disappears, the remnant of aseptic urine is disposed of by the circulation. This theory, I believe, will account for the occasional absence of a second kidney in cystic disease. It certainly is singular that nature should be so often remiss here. I have yet to learn of a fœtus born with but one kidney. Whoever heard of an infant with one lung or with one testicle (except ectopic) at birth?

The cyst may burst into the peritoneal cavity or into the loose, cellular tissues.

The most common termination for it, however, is to gradually destroy, by mechanical pressure, inflammation, pain, and wear on the constitution.

Obstruction of the ductus communis choledochus, when permanent, is inevitably mortal, unless the gall can reach the bowels by some route other than the duct.

The etiological factors of causation are essentially the same here as with the kidney, but owing to the wide difference in anatomical arrangement, and the physiological properties of the bile, its retention, with cystic distention, is one of the most formidable complications which the surgeon ever can be called on to deal with.

The only pathological condition in connection with the liver, apt to be confounded with simple obstruction, is that dependent on echinococci and hepatic abscess. The parasites of hydatic elements gain access through the digestive organs usually, and infest the gall-bladders and hepatic tissue by mounting the cystic duct.

A cystic formation, originating from those entozoa, may undergo rapid development and speedily destroy life, if not relieved. Such a case I saw in a boy seven years ago, in whom one of those masses developed within a week, as nearly as could be learned. They sometimes take an opposite course, however, as the eloquent Watson relates in his incomparable "Lectures on Physic." (3d Amer. Ed., page 512.)

His patient was a young nobleman, in whom, while examining for chest disease, he found a large tumor over the area of the gall-bladder, with a smooth, convex outline. The young man never suffered the slightest inconvenience from it.

He died some years later, when, on post-mortem examination, the cyst-wall was found shrunken and collapsed, and filled with the husks and débris of liver flukes, long since defunct; these remains were now entombed within the envelope, whence they had drawn sustenance.

The gall-bladder is capable of enormous distension. Lawson Tait tells us how he has mistaken it for an ovarian-tumor (*Lancet*, May 12th, 1890.) The gall-duct must share this property of extreme dilatation with it to a large extent, else we could not account for the passage of the immense angular and faceted biliary calculi which find their way into the intestine, and escape without detriment.

When the bile is shut off from the intestine we have most marked and unmistakable symptoms of serious trouble. If the bile is dammed back it seeks a temporary outlet through the blood, when the kidneys come to the relief of the liver, and eliminate large quantities of bile through the urine.

Owing to the absence of the secretion with the ingesta in the intestine, digestion is deranged, and, independent of auto-intoxication, in time the patient will sink from malnutrition or inanition.

A rupture of the cyst under these circumstances, when the bile has become concentrated and inspissated, must be followed by a fulminant peritonitis. Generally, as the walls of the gall-bladder spread upward, they excite a localized perihepatitis which glues the gastro-hepatic omentum, the cyst, and parietal peritoneum together in such a manner as to now safely confine the accumulated bile, and make the incision into it a safe and simple expedient.

Malignant disease starting in the stomach as a secondary growth, involving the gastro-hepatic omentum, by contiguity soon extends into and implicates the secreting structure of the liver within the capsule of Glisson, which, when in close contact with the conical terminus of the gall-bladder, may cause obstruction, partial or complete. However, considering the relative frequency of cancer and sarcoma in the hepatic tissues, the absolute arrest of the gall-flow by infiltration or contraction is rare. I saw two cases, recently, which demonstrated this conservative provision of nature in this respect. In one, a young woman, a sarcomatous growth had nearly tripled the normal volume of the organ, and yet there was no involvement of the biliary passages. With the other, who was an aged man, with multiple nodular disease, likewise the passage to the bowel was patent.

The symptoms peculiar to cystic obstruction have reference to secondary conditions dependent solely on arrest of hepatic function in the beginning, but later on to systemic intoxication, with its attendant and contributive consequences.

We will have the same colicky pains, loss of appetite, and loss of bodily strength, disordered digestion, and localized fullness when the cyst's contents advance towards the surface, as encountered with the organ in the loin.

Although the pancreatic or thoracic duct may close and become encysted, and watery tumors in other organs or tissues within the abdomen arise, their occurrence is rare; and what has been said of cysts

formation elsewhere situated, will generally apply to them.

TREATMENT—PALLIATIVE AND RADICAL—OF SEROUS CYSTS.

The prodigious progress wrought in operative procedures of late years has largely revolutionized the surgical management of new formations.

Since we may at our leisure cut off, as it were, the corporeal from the psychological being artificially, and place our patient in the quiet, lethal sleep of anæsthesia, sensation is in abeyance, and we strip an operation of all its former horrors. Besides, now, those harrowing anticipations of the dreaded ordeal are something of the past.

On the part of the operator, his case judiciously selected, he may promise recovery, frequently, with almost a certainty. He feels no longer the terrible apprehension of former times, but nerved with a confidence born of a correct knowledge of the application of modern resources, of anatomy and its cognate studies, combined with ample practice, critical observation, and extensive experience, he proceeds to lay bare the most delicate and vital structures at his leisure.

It would seem, then, that the question of how those local dropsies or simple serous cysts are to be managed, was finally settled beyond dispute or argument.

But the human body is something more than a machine, and there are many circumstances which demand our most careful consideration before extreme measures are resorted to.

No one would press for a surgical operation in the aged, or one suffering from a serious constitutional disease.

Probably, with the majority of cases, those simple, non-proliferating cysts, in the course of time spontaneously disappear, or remain in a quiescent state, giving little inconvenience, except by their weight.

Further, the extirpation of them does not always warrant their non-return, as the systemic predisposition to their reappearance remains; and although they may not return in their original nidus, they often do elsewhere, after a limited time.

An extensive, free incision into the abdominal walls results in a diminution of power and a tendency to hernia. When evulsion of the sac entails tedious detachments of adhesions, a viscus may be lacerated; we may have troublesome hemorrhage or ultimate active inflammation.

We must not allow ourselves to be deluded by the records of palatial hospitals, as their statistics can scarcely be regarded as reliable criteria for the isolated rural practitioner. Not that they are wanting in truth, or are varnished, but because there is but little comparison, often, in the facilities for operating. In many hospitals the cases are selected with great care; the operator is supported by a staff of trained assistants, accustomed to operations; he has everything in the way of appliances and instruments which art and a lavish outlay can provide. Added to all, good nursing, and fair hygienic surroundings.

When cystic disease threatens to compromise health, and is the source of pain or discomfort, internal remedies will make no impression on it, and we are obliged to actively interfere in many cases. The elder generation of surgeons and practitioners recommended physiological measures of relief when the cysts were of recent growth in the pelvis of the female. They recommended marriage and childbearing. Their premises were sound, for when fecundation followed copulation, the immediate active vascularity in the former languid, congested capilliaries soon aroused the latent vitality in the reproductive organs, and all superfluous adventitious productions of recent growth and moderate size underwent degenerative changes and disappeared. Others, of greater volume and of compact capsules, as the gravid uterus, raised out of the pelvis, were torn from their attachments as crushed as an egg shell against the sharp ridge of the pelvic brim. The parturient state passed, and involution complete, nothing remained of the adhesions or the cysts. If they did, a repetition of the same treatment was prescribed. Simple cystic contents are quickly taken up by the absorbents, and the remaining shell undergoes rapid atrophy.

Palliative treatment consists in measures intended to effect the absorption or arrest the advance of these excrescences. A well-adjusted bandage seems not only to give comfort and support, but also to favor their diminution in size.

I have never seen any benefit derived from massage or electricity, either through their physical, vital, or dynamic action. When they do seem to yield to these agents, I think it is through psychological effects rather than any direct specific action, as it is well known that many varieties of motion or sudden mental impression will often exercise a most marked influence on every variety of neoplastic growth.

When it becomes imperative to remove a simple, barren cyst by surgical operation, we may proceed chiefly by two methods.

One contemplates the puncturing and draining of the sac, with its irrigation and destruction of its secreting cells, by the action of an agent acting locally. This may be designated the conservative or partial operation. The other is the more radical and bloody. It embraces the exposure, detachment and total extirpation of the capsule.

The former method, in a general way, is by all odds the most desirable. By it, in the vast majority of cases, we succeed in effecting a rapid and permanent cure. The simple puncture and evacuation are not attended with the besetting difficulties and dangers which accompany the total excision, even in the hands of the most adept. No general anæsthesia is needed; the local, analgesic action of the spray from a syphon of Vichy, or of some ether dashed on the part, in a state of pulverization, is all that is necessary, when we wish the avoidance of cocaine impression on the reflexes. When no serious obstacle lies in the way, this very simple expedient should commend itself to us for very many reasons, which are only necessary to mention. Among the most prominent, we may take the dispensation with assistants, which is no small item with the poor. The avoidance of an extensive mutilation or shock; and, besides, the escape from the serious lethal effects which may follow the administration of a general anæsthetic in one who suffers from organic disease. No instrument is needed, under ordinary circumstances, except a few perforated needles of various sizes, and a good double-injecting syringe.

There are, however, a few things, formerly observed as trifling details, if ever noticed at all, which now must be regarded in the most minute detail. I refer to the preparation of the hands, instruments, and the field of operation.

As has been already stated, these cysts are of a low organization, composed of primitive, simple elements, so that when their integrity is in any way rudely disturbed, they often suddenly disappear.

Hence, the reasons why some authors have found rupture of the cyst-wall, by a sharp blow, when of medium size, very often effectual and permanent in its results. (Velpeau, Leçons sur les Kystes, Chirurg. Vol. IV, p. 300.) I can see no harm in even bringing moderate power to bear on intra-abdominal serous cysts, and crushing their wall in by judiciously applied force. Judging *a priori*, to me there seems no valid reason why this disorganization of the tumor should involve any danger whatever.

When we proceed to attack a tumor by simple puncture, we have two main objects in view: to drain away its contents and obliterate the capsule by inflammation and absorption. The simple emptying alone, I have found in many cases all that was necessary. It is important, nevertheless, to leave a free vent, as the presence of any remnant of the fluid seems to act as a stimulus and invites a relapse.

When the cyst is an old one, or when it refills, we must, after evacuating, inject the sac with some antiseptic, irritating material which will chemically unite with the protoplasm and induce adhesive inflammation. Nothing is more efficient for this purpose than mercuric sublimate, in proportion of one to two thousand, injected after the sac has been well drenched with sterilized water and thoroughly drained. An objection to it is that now and again we may salivate our patient; hence, the reason that many prefer thymol, which is equally efficient and devoid of corrosive toxic properties.

I have had such happy results with the simple treatment outlined above that I feel justified in recommending its adoption in the treatment of the vast majority of cases of simple cysts, whether situated near the surface or deeply.

Should we have a suspicion that the growth lay beneath, or so convenient to an important structure as to make direct puncture dangerous, we may divide the super imposed parts with the scalpel, and not thrust in the trocar, till the bare cyst wall comes into view.

When the contents of the capsule have undergone myomatous changes, or when it is presumed that the neoplasm may be readily dislodged, either from its pedicle or the parts with which it has fused, we essay its complete removal by an abdominal section, as a preliminary procedure.

If no adhesions have formed, and the growth is of but moderate size, there will be little loss of blood, and its removal is simple and rapid. But when there has been much antecedent inflammation, and the investing envelope assumes a sort of flattened-cut shape, contracting adhesions as it insinuates itself between the varied duplicatures of the peritoneum, the peeling off of the parietal layer, without considerable hemorrhage and danger of laceration or rupture of parts which must be invaded, is very tedious and difficult, and may entail such shock that the patient never wholly rallies from the operation. Indeed, not infrequently its removal entire is an impossibility. Under these circumstances, we may open through the tumor, drain or scoop out its contents, and cut away with the scissors all that part of the sac within reach, staunch the hemorrhage, flush the peritoneal cavity, and drain or not, according to requirements.

These intra-abdominal operations for the extirpation of cysts should not be undertaken until full preparation has been made in the way of ample supplies of every description. At least three assistants will be necessary. Every step demands our most assiduous attention, for we must remember that in opening the cavity of the peritoneum the *ultimate* results will often depend on the observance of the most apparently unimportant and trifling detail.

Much depends on the time consumed in operating, and the extent of incision made. Air can enter in the peritoneal cavity, but we cannot get it out; and the longer the visceral nerves are denuded, and the greater their area is exposed to thermal influence, proportionally great is the shock.

It is indisputable, then, that the radical operation must always be regarded as a most extreme measure. We have seen that most distressing sequelæ may follow the bruising to which the parts are necessarily subjected in it—the adhesions, intestinal obstruction, hernia, or impaired functional power of those organs or structures, the full and free action of which is so indispensable to the enjoyment of health.

THE TREATMENT OF CYSTIC FORMATIONS.

Cystic formations proper, the retention cysts of Virchow, are managed on the same general principles as ordinary cysts. Some of them admit of palliative measures only, which entail but trifling dangers to life; while others, a small minority, may be permanently disposed of by a radical course, which, however, contemplates the complete extirpation of a physiological structure.

Probably one of the most frequent and fatal varieties of retention cyst within the abdomen is that connected with the kidney, and known as hydronephrosis—literally, dropsy of the kidney; but clinically understood to designate a back-flow of urine, attributable to an impediment. Pyonephrosis does not depend on the same etiological factors; hence, if it were described as what it really is, as a renal abscess or renal phlegmon, it would convey a clearer and more accurate definition. The object in view in the surgical management of hydronephrosis is to remove the obstruction and empty the distention by way of the ureter; drain it through an aperture externally, or go to the fountain head and lift the kidney itself out of the body.

Owing to the rapid infection of the wound after opening into a distended capsule before the days of antiseptics, the mortality was so great, even in the hands of the most experienced operators, that any intervention involving mutilat on was discouraged, and hence the majority died, unrelieved, who were afflicted.

Since the time of Listerism, or aseptic surgery, there is no organ of the body in which the domain of modern surgery has had a more salutary influence than the kidney: and, to day, thousands are saved, who but recently must have perished unrelieved.

The conservative or palliative treatment of hydronephrosis consists in drawing off the urine temporarily through an aspirator, with a view of relieving tension.

With a man under my care six years ago, who was struck with violent force by the fly-beam of a derrick, in the right groin, his urine diminished fully half in quantity, and almost immediately a painful fullness appeared forward, over the right iliac plate. I punctured it on four successive days, drawing away from a pint of urine on the first day to a quarter of the quantity the last time. He made a good recovery. I cite this as an instance of temporary obstruction of the urinary duct, probably from a blood clot.

The next means of relief consist in making an incision from behind (nephrotomy), and carrying the urine externally. I am acquainted with no instance where permanent success has attended efforts directed towards sending the urine into an intestine. The

last and most radical of all measures involves the total removal of the kidney, nephrectomy.

The latter is undertaken as a primary operation when the sac, urine, and gland are all swept away at once. As a secondary measure, it is performed when, sometimes after nephrotomy, we are confidently assured that little secreting substance remains, and that the other kidney unaided is competent to do the work of elimination.

The choice of operation then, when choice is permitted, lies between nephrotomy and nephrectomy. The latter may be a procedure of selection, while the former is one of necessity.

In order to reach an approximate estimation of the relative dangers of each in the pre-antiseptic times and since, with these renal operations, I will quote, in abstract, from an able brochure by M. Jeannel, of the Toulouse School of Medicine, published in the *Gazette Hebdomadaire*, July 19, 1890.

Of secondary nephrectomy he says: "It is less easy of execution, and attended with greater danger to life than when the primary operation was done under proper conditions; in any event, in the secondary operation there is less space to manipulate in; the large, empty, hydronephrotic pocket, suppurating, irritating, contracted, and firmly bound to neighboring organs, is much more difficult of management than when the kidney, supra-renals, sac, and all, are detached at once."

He insists on the danger of a hydronephrosis becoming a pyonephrosis through contamination; and he cites the reported cases in the hands of Nicaisse, Brodeur, Le Dentu, Kaufman, Braum, and Roemer, in which, in spite of rigorous antisepsis, nephrotomies (primary) were followed by suppuration and death.

Quoting from Guyon (*Annales des Maladies des Organes Genito-Urinaires*), he gives the mortality in primary operations as thirty per cent.; in secondary, ten per cent.; though, however, he asserts with emphasis that, with the manual of operation more precise, and the patient in a fair condition, it is always the safest to do the complete operation in two stages; the first being a nephrotomy, and second, nephrectomy.

Messrs. Jeannel and Brodeur together performed 18 nephrotomies, with no deaths; while of 44 nephrectomies—his own and others—11 died.

M. Jeannel, in concluding his monograph, calls attention to the causes of death in nephrectomies, which he believes were mostly preventable, and attributes them to either the technique of operation or impropriety of performing it. Hence he gives items as to causes of lethality with different operators.

Esmarch, Meadows, and Billroth each lost one from hemorrhage. Schleileg and Czerny, each one from absence of another kidney. Czerny, one from tear of the peritoneum and colon. Verneuil, one from an infection wound of the peritoneum. Watson and Goodell lost one each from unknown causes.

Now, while it is clear that those operations embracing the evulsion of a urinary cyst are practical and of utility, yet there are often insurmountable difficulties in the way.

The safest, least injurious, and most practical route to the kidney is by way of the lumbar incision. With the last rib resected, reasonable space is afforded to manipulate without entering the peritoneal cavity. As the general peritoneum has not been divided, the prospect of hernia following is not great. Being then on the border-land, and yet not within the serous sac, the operator is not annoyed by protruding viscera, and can hence proceed with rapidity. The record of one of our own countrymen in those renal operations made posteriorly should not be overlooked, for his success is so far unparalleled.

Dr. George D. Hamilton, of Columbus, O., has, within the past year, performed successfully five renal operations on patients of different ages—two nephrectomies, two nephrotomies, and one nephropexy.

The operation of nephrotomy is performed by making an oblique incision over where the kidney normally is placed. When the muscular parts are divided, and the loose fat in the way of the kidney is pushed aside, the distended outer capsule, with the pelvis, are seized with the thumb and the fingers and herniated into the wound. After all hemorrhage is controlled and the wound well cleansed, a puncture is made into the hydronephrotic pocket and the urine allowed to run off. Now, if the sac is not adherent, its redundant, flabby, collapsed walls may be gently drawn through the incision, and cut away, when its margins may become sutured to the integuments. By most rigid antisepsis, henceforth, and proper care, septic infection will be prevented and the fistula kept open. Great care must be taken here in making the deep incision, not to mistake the lumbar fascia for the cystic covering and open the peritoneal cavity; or if the parietal peritoneum has taken on adhesions with the bowel, and we divide it, a gush of fæces will besmear everything, greatly complicating and protracting the operation. Accordingly, we must grope about, feeling our way with the greatest caution, and using the scalpel but sparingly, until we are positive that we commit no mistake.

The final and entire removal of the cause of hydronephrosis entails the ablation of the kidney. This is done by incision, similar to the one adopted for drainage. When it is felt and secured, it is decorticated; the vessels secured *en masse*, or separately. After the secretory structure has been removed, the shell is secured in the wound by a few cat-gut sutures. Now the chasm is well packed, and the incision is closed by a granulation process. Encysted, renal pus, is evacuated; its exciting cause sought for, as a calculous or other foreign substance, and the wound treated openly.

Hepatic cysts, whether serous, purulent, or hydated, are not so safely remediable as those of renal origin. The liver having but one common terminal duct, and being a solitary organ, total arrest of function in it must be quickly mortal; hence, though the route to it were of easy access, yet, nevertheless, when the pathological conditions involve the gall-bladder, or the ducts, operative measures must be of little more than temporizing expedients in the majority of cases. From an anatomical standpoint we can understand the difficulties which lie in the way. Unless there have been pus, plastic inflammation, a previous localized peritonitis, we must open the peritoneal cavity to expose the gall-bladder, or the free surface of the liver.

Happily, however, if the distension is either hydatid or serous, it may be drained away in precisely the manner as those heretofore described. Certainly there may be severe leakage through the puncture into the peritoneal cavity, but this will not cause serious constitutional disturbance.

With pus accumulations and cystic formations we must proceed with caution, and divide the operation into two stages, or more, if necessary. To drain away a phlegmon lodged deeply beneath the capsule of Glisson, infection of the peritoneum must be avoided, or all is lost. We accordingly commence by making

an aseptic incision into the abdominal wall, immediately over the most prominent fullness, opening down until the parietal peritoneum is devided, when the gap is stuffed with gauze and covered by a firm bandage. In a few days—usually about three—the packing is removed, when adhesions are found to have formed, and the abscess may be opened and drained without danger of peritoneal infection.

In cholecystotomy, in the absence of recent or ancient adhesions, we practically adopt the same plan. When the gall vent has permanently closed and an effort is made to drain into the intestine, an operation known as cholecystenterostomy is done. I have never performed it, or ever saw one who survived it. Any one familiar with the many adhesions which form in the vicinity of the common bile duct, with the altered indurated, or softened state of the tissues in chronic cystic disease, can readily appreciate the difficulties in the way. Added to this, even though a connection were practicable, the loss of blood, or the laying bare of the parts, is only too frequently followed by mortal collapse.

I would warn against the propriety of ever making an exploratory incision in any case wherein it is proposed to do an operation on the hypatic tissues, as it is liable to be followed by shock, and it exposes the patient to a needless danger. So that when it is proposed to inspect the parts by laying open the visceral-envelopes, we should have everything in readiness to go rapidly through such an operation, as the condition of things may require.

CONCLUSIONS.

From the foregoing it is evident that with the revelations of the microscope, and intelligent study of the histological elements and the pathological changes in serous cysts, a sound knowledge of them has become possible.

By the aid of anæsthesia and germ destroying agents, their treatment has undergone vast changes, and now that sepsis and pain are no more, in dealing with them, few can wholly elude the efforts of the practitioner in his attempts to dislodge them.

My aim here has been to reawaken attention to the importance of the study of this very interesting class of pathological formations.

Of course no attempt has been made in the way of an analytical, or minute study; for any one desirous of pursuing the examination of the subject in all its details, will find numerous treatises on the subject convenient.

My views here expressed are not based on speculation and theory alone, for I have had considerable practical experience in dealing with this class of neoplasmata. We have truly made stupendous progress, but yet all operations involving the abdomen are not without danger. And explorations entail mutilation; hence, conservatism should be the word, and procedures involving much loss of blood should be resorted to only as a *dernier ressort.*

But when the time arrives, however, that we must act, we should proceed only when we have thoroughly qualified ourselves by study, experiment and practice, and we are fortified with a consciousness of a comprehensive knowledge of all the difficulties and accidents which may lie before us. Then, should the case end in disaster, we are easy in mind, and know that failure was attributable to influences beyond our ken to either modify or prevent.

Dr. Eug. B. Dickson, of Chicago, was married to Miss Marion Bronson, October 21.

ON THE NATURE OF THE COAGULATING PROCESS.

By SAMUEL WOLFE, M.D.,
PHILADELPHIA.

In investigating the phenomena of coagulation, we should not forget the position which coagulable substances occupy in the scale of evolution of non-living to living matter, a scale which evidently has many stages in reaching its completion, but has, nevertheless, a perfectly definite limit. In this transition the ultimate limit is that state in which the tissue unit has become endowed with its full capacity for energy, which energy will have its character defined by the position which it has attained. If nerve, cell, or fiber, it will be of one kind; if muscular fiber or secreting cell, of another, or another kind, and so on.

In this transition all the component parts of these units have at one time been constituents of the blood, and as such had most likely already passed the boundary line between living and dead matter. Let us, for a moment, trace the course of food in its conversion into protoplasm. Up to the time when the food materials leave the alimentary canal by passing through its mucus lining, the chemist can imitate all the processes which it has there undergone, in his laboratory. It is true he must derive some of the material with which he proceeds from outside sources. But even though he must borrow pepsin, trypsin, or amylopsin from an animal source, yet he can conduct all his operations without any necessary contact with living matter. But when, in their onward course, these food materials have reached elaborating organs like the liver and the mesenteric glands, and have had the stamp of vitality impressed upon them, he stands powerless to imitate, nor can he, by any formulated chemical laws, explain the subsequent changes. From henceforth, until the limit of development already alluded to is reached, we must, in the present state of our knowledge, be content to call the changes molecular or vital. But while the chemist cannot solve the problem further, the biologist does not stand idly by. He knows that though endowed with life in the normal course of development, matter at this stage manifests no energy. Though evolved at the expense of energy, derived from previously-developed living material, the developing matter is engaged in storing force, not in giving it out; and thus it goes on, until the limit of its organization is reached; until it has become an integral part of the tissue to which it is destined. Now, matter in this developing state is spoken of as in the ana-state. When fully developed, as in the meso-state. With the exception of the red corpuscles, which probably have no destination as such, beyond the functions they fulfil in the blood, no portion[1] of that fluid can be regarded as having reached its meso-state, and, therefore, in its normal course it has as yet evolved no force.

Now let us take matter that has reached the meso-state; that has become an integral part of a tissue, and see what becomes of it. It is not destined to remain idle; natural processes are too economical to permit this. Sooner or later demands will be made for the latent force which it holds to accomplish work. Under some stimulus the pent-up energy must be evoked, and when such stimulus presents itself the complex product under consideration is given

[1] The water, and salts, and products of excretion are not to be regarded. Our concern is with the proteids derived from the food.

over to that fell destroyer, oxygen, which, in the act of seizure, liberates its force with explosive power, and in the combination resulting a more simple product appears—one which is, perhaps, to serve no further use in the economy, and is, consequently, consigned to an agent capable of its removal.

Such explosions, according as the stimulus is weak or powerful, result in either a partial or total loss of the stored up energy. If only partial, repetitions will complete the work of destruction and the consequent liberation of force. Whether complete or incomplete, conditions of living matter in this stage of expenditure and destruction are known as kata-states.

To recapitulate: The constituents of dead food rise in anastatic steps (passing the while through the blood) to the dignity of the mesostatic crisis (having then reached the tissues and representing cells or intercellular substance), and then, under appropriate stimuli, by the agency of oxygen, are either suddenly precipitated, or pass, by more gentle gradations, through the kata-state, and are once again dead matter.

The meso-state is the biological type of perfected protoplasm; it is the sample product of life's laboratory; the state to which all living material, in its developmental stages, tends. But when the machinery becomes disordered or stopped, imperfect, unfinished products appear; yet, though imperfect or unfinished, still endowed with vitality, and, therefore, capable of yielding force; capable of passing through the kata-states. Now, in passing through these kata-states, they yield products which, in the normal order, do not appear. Hence we may assume that when, from any cause, the partially vitalized matters of the blood, which are destined to reach their meso-state only when they have become tissue, are arrested, products and properties will manifest themselves which could not before be found. And of this order are fibrin, fibrinogen, paraglobulin, and fibrin ferment. Oxygen here, too, is doing its work, and stimuli to the progress of the katastatic course are present. The fibrinoginogen, which, during release from the cell that contained it, would probably, had it reached its normal meso-state, have been trypsinogen, inogen, or some other elaborated product, of the many which may be assumed to exist, besides those which have been discovered, in the various types of fully differentiated protoplasm, is here converted into fibrinogen. We need, therefore, no theory to account for the blood remaining liquid while normally circulating in the vessels, if we regard it as owing its powers of coagulation to substances which never appear in it under these circumstances, and which do not appear because its protoplasm has a higher destiny, and because there is here no stimulus to its oxidation; no interference with its progress to its normal meso-state; in short, no katastatic manifestation, and hence no release of vital force. According to this view, the theory of Lister, that the blood has no natural tendency to clot, is more nearly true than that of Brücke, who holds that the tendency is always to coagulation, but that its normal relations exercise restraint, and thus prevent its solidification. The coagulating power of the chyle when past the first series of mesenteric glands; the still greater powers in this direction as the venous current is approached, and their further increase in the blood, together with the coagulability of muscle substance just prior to putrefactive changes, all point in the same direction. In all we may assume that protoplasm has passed into a kata-state, short of its normal meso-state. No less applicable are the results of disease; the disordered functions, and the appearance of abnormal substances, and of morbid construction, which, however wide their divergence from the physiological and histological standards, can yet be distinctly recognized as their perverted congeners.

Society Notes.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, September 10, 1890.

The Vice-President, JOHN B. ROBERTS, M.D., in the Chair.

A NEW METHOD OF DELIVERING THE FŒTAL HEAD.

DR. BENJAMIN T. SHIMWELL read a paper with the above title.

Nature's manner of delivering the fœtal head has been followed by obstetricians from time immemorial; recognizing the fact that the occiput is born under the symphysis pubis in normal labor. The face and chin stretch the perineal body, then force their way out, requiring an especial amount of care to prevent tearing of this tissue. The extent of injury to the pelvic floor is not properly appreciated; if the superficial tissue of the perineum is safe the attendant congratulates himself on his possible skill; or if aware of deeper injury, feels grateful that no apparent injury is shown to the watchful eyes of the nurse or patient's friends.

Thus do thousands get out of the confinement-bed ruined in health, carrying into the future injuries that must of necessity bring ill results. Various plans have been suggested to support and accommodate the perineal body to the oncoming head.

It is strange how often the anatomical construction of the perineum is overlooked, and considered merely as a space-filler. It is by this that so much injury is done. The gynecologist's specialty lives by these results.

These are the reasons, hastened probably by experience gained in the above manner, that has induced me to write this paper. The theory that will be advanced, backed by my application of it in a great number of cases, is evidently new; if not, it has not come to my knowledge by reading or otherwise. The advantage of this method is the saving of the pelvic floor from injury either superficial or deep. No attempt is made to show expedition, but a modification of the ordinary method of labor changing the direction of the impinging force.

Naegele says that seventy out of every hundred vertex presentations are in the first position, the other thirty are occiput to right and posterior. The remaining positions are exceedingly rare.

When the head presents in the first position the body of the child must not be overlooked. The back of the child must present to the front and left, the chest to the back and right; therefore at right angles with the vertex presentation of the head at the superior strait. The important point in this theory is the rotation of the head to the symphysis pubis. The manner of rotation of the head is mooted. Pajot claims that the shoulders participate in the rotation, but contradicts himself when he furthur says: "That it is above all the shape of the child's head which decides the character of the movement;" also, "That the occiput will, therefore, be carried forward less on

account of the direction of the forces which impel it, than because of the necessity for accommodation of the cephalic surfaces to the pelvic surfaces." All writers admit that after expulsion of the head occurs restitution takes place, that in a case of first position, after the head is delivered, the head turns with its occiput to the left thigh—that is, in the direction that the head presents at the superior strait; this is an untwisting of the neck.

Gerdy claims that this is "an external expression of a movement of the shoulders within the pelvis, by which the biacromial diameter passes from the transverse to the antero-posterior diameter, the head following the internal rotation." The folly of this assertion is on its surface. The head is free, and the neck and body are constricted by the vagina and the uterus, and if rotation does take place, can we overlook the anatomical relation and action of the atlas vertebræ? Would not the weight of the head allow of the rotation internal without its external manifestation?

Penrose (Hirst, vol. i, p. 571) says: "While the head has rotated, the body of the child, still in the cavity of the uterus, has been tightly grasped by the firmly contracting walls of the uretus, and has not participated in the movements of the head; hence the shoulders are still oblique at the superior strait, consequently the neck of the child is twisted." The latter theory, according to my experience is the true one. The fact of the anatomical construction of the cervical vertebræ of the child cannot be overlooked. This arrangement allows of a rotation of one-fourth of its circumference to take place without injury to the spinal cord. Therefore, if Pajot's theory of the accommodation of the cephalic surfaces to the pelvic surfaces, rather than the application of the force, is true, then it can be seen that rotation of the head is possible without the shoulders. Then, again, the head is not free to wobble around the pelvis when it has reached such a condition of flexion, neither is the neck a rigid body depending on the shoulders for its position. If the theory of shoulder rotation is so, then nature's method is superfluous; for why should the biacromial diameter be changed from its oblique position, which is nearer the antero-posterior diameter, to the transverse, then rotate back again beyond its former position to the antero-posterior.

Playfair believes in partial rotation.

Believing, then, that the shoulders still maintain their oblique position through all the stages of the delivery of the head, what occurs when rotation brings the occiput directly antero-posterior? This has been accomplished by the rotation mentioned of the atlas on the axis vertebræ to one-fourth of its circumference; this having occurred, the delivery of the head takes place, then immediately external rotation or restitution occurs, that is, the neck untwists.

The outlet of the female pelvis is four inches antero-posterior and transverse. The antero-posterior is possibly increased a half inch by extension of the coccyx. These measurements are decreased by the soft tissues; this is more marked in the antero-posterior by the rectum and perineal body. As the head in the last act of delivery begins to extend, we have presenting the cervico-frontal diameter, which is four inches; this has to pass through a space that is but four inches, possibly four and a half inches, lessened by the perineal body, which is at this stage excessively stretched and attenuated. As the safety of the perineum is an exceedingly important matter, it occurred to me that this might be accomplished by lessening the size of the impinging body and transferring the extending head into another direction. It is the nose and chin that rupture the pelvic floor, therefore if the direction of this force can be changed to some other point than the junction of the levator ani muscle, it can be easily seen how injury to this muscle can be prevented.

When the labor has reached this stage, I place the woman across the bed on her back, knees well drawn up, then compel her to breathe with the mouth wide open to prevent bearing down. As the head presents in the oblique direction and to reach the antero-posterior diameter it rotates, twisting the neck, the first step in the method is to reëstablish the direction of the first impingement; this is not done until the cervico-frontal diameter is reached; *this must be complete*, then forcing the head into extreme flexion by grasping the presenting occiput by the hand (in non-instrumental labors), I begin my rotation; the first step is to untwist the neck; this accomplished, the head presents cervico-frontal to the left anterior. I then take advantage of the same anatomical construction of the cervical vertebræ that allows of the normal rotation, and rotate one fourth in the opposite direction, that is, to the left. The cervico frontal is then transverse, the neck lying on the labia of the left side, the forehead beginning to engage the soft tissues of the right labia. What is now presenting to the antero-posterior diameter, or, what is more important, to the perineum? The biparietal diameter, which measures three and one half inches, therefore less tension on the perineum. The possibility of delivering the head in the transverse diameter has been questioned. The articulation of the head to the spinal column is wisely arranged; if no other object than birth was intended, it has well served its purpose. The diameters of the extending face are those of a right-angle triangle, the hypothenuse of which is four inches, the perpendicular three inches, the base two and four-fifths inches. The mechanical advantages of this is apparent. If the measurements had been those of a triangle, the impossibility of delivery is easily seen, the head could not be born as long as the perineum existed. The sweep of the extending head would be the same at the chin as at the forehead, and the perineum would be torn in every case and in every succeeding labor; but the measurements are those of a right-angle triangle, and of a necessity the chin must recede when complete extension takes place, so when extension is made in the transverse diameter of the inferior strait the chin does not impinge on the ramus of the ischium.

Having got the head into this position, I begin the last stage of the delivery of the head. The head has been all this time in extreme flexion, then extension is performed, the soft tissues of the labia push aside, and nose follows on forehead, chin on nose; delivery is complete, and the pelvic floor is safe. The head then untwists to its normal position.

Discussion.—Dr. E. E. Montgomery: I think that the members of the Society are greatly indebted to Dr. Shimwell for the graphic presentation of this method of dealing with the delivery of the head and effort to save the perineum. This certainly is a violation of that old principle which has been handed down the ages, that "meddlesome midwifery is bad." When we consider that all progress in obstetrics and every step in advancement has been in violation of this principle, this thought may not be considered an objection to this procedure, which certainly seems to be one which should be serviceable. But, not having

had experience myself, I am unable to say more than these few words in commendation of it.

Dr. J. M. Baldy: It seems to me that the remarks of Dr. Montgomery, in regard to meddlesome midwifery are true as regards pathological processes, but not as regards physiological processes. Certain it is that in almost everything in which we have attempted to interfere with physiological processes, we have found that they have been carried on a great deal better by Nature herself than by any so-called improvement that we have made on her. If Nature had meant that the head should be delivered in the transverse diameter of the outlet, she would have given us some indication of such desire. On the contrary, she has shown us very clearly and distinctly that the head was to be delivered in the antero-posterior diameter. It is probable that the head can be delivered in the transverse diameter, as Dr. Shimwell has pointed out, if all the measurements are of average size; but all of us know perfectly well that it is the exceptional head that we come across, and not the typical head. Many of the heads are large, and the higher we get in the stage of civilization the larger the head. The normal head may go through, but I doubt not that Dr. Shimwell will run across many cases that he will not be able to deliver in the transverse diameter. Unless the head will pass easily, we have here no room for the extension of the outlet. It is a fixed quantity bound by bony walls—the ramus of the ischium on both sides—and there can be no distention. On the contrary, in the natural methods of delivery we have free room for extension taking place through the perineal body and the soft part of the lower part of the pelvis. Now, it may be that there is danger to the levator ani muscles from over-distention, but at the same time I conceive, and it has been my experience, that the danger to these muscles is greater in proportion to the amount of interference we give to the perineum. In other words, we have here a hard body starting from a given point and progressing at a certain angle to a certain point at which it meets a plane of resistance, that plane of resistance being the soft parts of the pelvic floor, and, if you will, principally the levator ani muscles. There is a well-known physical law, that any body moving in a given direction and meeting with an obstacle, will be deflected at a certain angle. We have this occurring in delivery of the head. The head comes down and meets a resistance, which, although not a fixed resistance, is sufficient to cause deflection in the line of least resistance. This line of least resistance is the opening of the vulva. If resistance is given to the head at that point, the head is prevented from bulging through the vulvar orifice, and the *vis a tergo* being still active, must be spent at some place, and that place is at the point of contact of the head with the pelvic floor. Taking the head, which is bulging the perineum and presenting at the vulva, we hold it back by pressure on the perineum, or by some other method; then we are going to have the greater part of the *vis a tergo* exerted at this one point. These soft tissues of the pelvic floor are capable of yielding to a certain point, and, when they come to that point, they are going to give, and there will be a tear of the levator ani muscles and the other tissues involved. This is where, I believe, the vast majority of tears of the perineum come in. All teachers teach that the head should be held back in some way or other, so that the vulvar orifice is not allowed to expand and the head protrude, as Nature intended; and by this misapplied force we bring about the accident we are trying to avoid. I have found in the cases in which I allowed Nature to take her course almost entirely, keeping the fingers from the head and perineum, except to make slight pressure and lift the head up against the pubic arch, that they have done better and I have had fewer tears, and those that have taken place have been of a minor degree as compared with those where I tried to prevent injury by supporting the perineum. Any support of the perineum whatever is pernicious. I believe that all the teachers and all the books are at fault in that respect. Nature did not mean to have the head held back and have the whole force spent on one part, when we have the elasticity of all the soft parts well anchored, so as to yield and to give room for the head to pass. Supporting the perineum prevents the proper stretching of these tissues, and prevents any good they may do in bulging the perineum and forcing the vulvar orifice open.

Dr. Shimwell: I am exceedingly sorry that some of my friends who have used this method successfully have not spoken. Dr. Baldy has raised the objection that a large head could not be born transversely, but the same objection applies to the antero-position as well. He overlooks the fact demonstrated by the mathematical figure, that we gain, as the chin is delivered, a fraction over one and a quarter inches. The head is born without impinging on the soft tissues of the pelvis.

I have tried this method successfully for a year and a half, both in primipara and in multipara. I have used it both in cases terminated without instruments and in those where the forceps have been required on account of loss of tone or from malformation on the part of the head or of the pelvic outlet.

In regard to Nature—Nature is not always a good worker. If so, why should we have a disproportion between the head and the pelvis? The outlet should be made equal to the head. With regard to the increase in the size of the head with advancing civilization, I know that; but is the pelvis unchanged? Is it not rather lessened? Has it not changed its size and shape?

The points advanced are, I think, no argument against the method. It is a safe method; it is an easy method; and the delivery is accomplished with perfect safety to the child and to the mother.

Stated Meeting, September 24, 1890.

Dr. Charles B. Penrose read a paper on

THE TREATMENT OF HEMORRHOIDS BY EXCISION.

My object in presenting this paper is to urge the more general use of Whitehead's operation of excision in the treatment of certain cases of hemorrhoids.

In 1887, Mr. Whitehead, of Manchester, reported[1] three hundred consecutive cases of hemorrhoids which had been successfully treated by the method of excision and suture. His operation is performed in the following manner:

1. The patient is placed on a table in the lithotomy position, with the hips well elevated.

2. The anal sphincters are then thoroughly paralyzed by digital stretching.

3. The mucous membrane of the rectum is divided at its junction with the skin around the entire circumference of the bowel.

4. The mucous membrane, with the attached hemorrhoids, is dissected from the submucous tissue, and the cuff or cylinder thus formed is dragged below the skin margin.

[1] British Medical Journal, February 6, 1887.

5. The mucous membrane above the hemorrhoids is then divided transversely, thus removing the pile-bearing area, and the operation is completed by suturing the upper margin of the severed membrane to the free margin of the skin.

The advantages claimed by Whitehead for this method of treatment are based on pathological and surgical reasons. He considers that the internal hemorrhoids, which are generally regarded as localized distinct tumors, amenable to individual treatment, are, as a matter of fact, component parts of a diseased condition of the entire plexus of veins surrounding the lower rectum, each venous radicle being similarly, if not equally, affected by an initial cause, constitutional or mechanical.

The operation of excision is the only one which removes this whole diseased area. It is, therefore, demanded for this pathological reason. It is in addition surgically more perfect than any other method of treatment, because it provides for the readjustment of healthy tissues with the object of securing primary union and rapid convalescence. It does not leave the sluggish ulcer of the cautery, nor is it attended with the pain and slow convalescence of the ligature.

My experience with this operation is limited to ten selected cases. Only those cases were selected in which there existed a complete circle of hemorrhoidal tumors surrounding the lower margin of the rectum, since for such cases Whitehead's treatment of excision seems to be most particularly adapted.

The details of the operation are simple and easy to execute. In dividing the mucous membrane from the skin it is best to begin at the posterior margin of the anus in order to prevent the blood from obscuring the field of operation. No skin should be sacrificed, even though there appear to be redundant tags around the margin of the anus. The skin always retracts somewhat and the tags shrivel and disappear before firm union has taken place. Failure to observe this rule may result in subsequent serious trouble. Kelsey[1] reports the case of a woman who had been subjected to a so-called Whitehead operation and who presented herself to him with a complete circle of excoriated mucous membrane, extending for one inch outside the anus. It is probable that in this case the operator had sacrificed too much skin.

On the other hand, the upper section of the mucous membrane should be made in the same horizontal plane throughout, in order to prevent subsequent ectropion ani.

The dissection of the mucous membrane from the underlying tissues is exceedingly easy, except in some cases of old—or long standing—piles. The attachment of the submucous tissue is very loose, and separation can be effected with the finger or with the handle of the scalpel. It is not always possible to dissect the piles completely from the underlying structures, as they may involve not only the mucous but the submucous tissues, and in such cases it is necessary to cut partly through the piles until the healthy mucous membrane above is reached. Repeated attacks of inflammation of course render closer the adhesion of the pile area to the underlying structures. In one of my own cases, where the piles had existed for forty years, and had frequently been inflamed, the adhesions to the two sphincters were so close that a few muscular fibers were cut away during the removal.

The amount of blood lost during the operation is surprisingly small. Whitehead states that he has often operated on severe cases and not found it necessary to twist a single vessel. In five of my cases no hæmostasis was necessary. Bleeding is avoided by adhering closely to the mucous membrane in the dissection, as the larger arterioles lie beneath the submucous tissue. The arterial bleeding occurs in those cases of old piles which have been subjected to previous operation or to attacks of inflammation, and in which dilatation of the rectal and anal arteries has taken place secondary to dilatation of the hemorrhoidal veins. The bleeding from the upper divided edge of the mucous membrane can be reduced to a minimum by following Whitehead's method of inserting the sutures as each portion is divided, or by adopting Marcy's plan of introducing a circle of shoemaker stitches of catgut around the mucous membrane above the piles before cutting the mass away.

Whitehead's advice is in all cases to remove the complete cylinder of mucous membrane, whether or not the whole of this area appears to be diseased. He gives this advice for the reason which I have already stated, that he considers the individual piles as but part of a general pathological condition, involving all the lower hemorrhoidal veins of the rectum.

Whether we accept this pathological view or not, it is best to follow this plan, and to make a complete circular division of the mucous membrane, as by this method the best surgical results are obtained, and ectropion ani prevented. I have seen a case in which only one-half of the circumference of the mucous membrane of the rectum was removed, and a few hours after the operation an œdematous swelling formed in the other half, which has now resulted in a hemorrhoidal tumor almost as annoying as the one for which the operation was performed.

In attaching the mucous membrane to the skin, Whitehead uses the interrupted silk suture. He never removes the sutures, but allows them to ulcerate through—a process which is very easily accomplished. In my own cases I have used the continuous catgut suture.

The treatment of these cases after operation is very simple. It is rarely necessary to use opium or the catheter. An opium and belladonna suppository introduced immediately after the operation, is, in most cases, all that is required. The bowels can be moved in from twenty-four hours to four days, and with very little pain. Absence of pain after Whitehead's operation is due to the thorough paralysis of the sphincters, and to the fact that no source of irritation is left beyond that of a clean linear incision, united without tension and without strangulation of tissue.

A glance at the histories of my own cases shows that they were all cases of aggravated hemorrhoids, in which the piles covered the whole circumference of the lower part of the rectum. In all the cases the disease had existed for many years, and two had been subjected to previous operation by the ligature.

In only one case was there anything like free bleeding during the operation.

In all the cases a suppository of one-half grain of extract of opium and one-half grain of extract of belladonna was introduced immediately after the operation, and this was all the opium required except in three cases, in which one-sixth grain of morphine was subsequently administered.

The catheter was used in only three cases, and in these for a period not longer than twenty-four hours. The length of time that the case is confined to bed depends to a great degree upon the social standing and the disposition of the patient. In my cases it varied from two to ten days. Every case should be

[1] New York Medical Journal, October 5, 1889.

able to sit up in four or five days, and to resume work in ten days or two weeks.

The bowels were opened without pain in from twenty-four hours to four days after operation.

No complications of any kind followed these operations. Union takes place quickly, and generally one dressing taken off when the bowels are moved, is all that is necessary. In no case was there incontinence from paralysis of the sphincters, or any tendency to stricture, from contraction of the scar.

Since the publication of Whitehead's paper his method of operating has been tested by many surgeons. The operation cannot be criticised on surgical grounds, as it is certainly the most perfect plan of treatment, surgically speaking, which has been proposed.

The immediate removal of the tumors, the coaptation of healthy tissues, and primary union, are substituted for slow strangulation by the ligature, or removal by the cautery and healing by granulation.

The applicability, or the necessity, of this operation in all cases of hemorrhoids, is, however, open to criticism. If we accept Whitehead's views in regard to the pathology of piles, and believe that the whole venous plexus surrounding the anus and the lower end of the rectum, is in a pathological condition in every case of hemorrhoids, even though there may be present only one or two isolated tumors; then, of course, the complete removal of this area is indicated.

But that this view is not true is proved by the thousands of cases which have been permanently cured by the ligature and the clamp. The method, however, is indicated in all cases of aggravated hemorrhoids where the vascular tumors cover the whole or the greater part of the circumference of the bowel. In such cases the operation presents no great difficulties. Statistics show that it is at least as safe as operation by the ligature or the clamp, and it is certainly followed by a more rapid convalescence, and much less pain and discomfort.

Discussion.—Dr. W. D. Green: I have had the pleasure of witnessing only a small number of Whitehead's operations, but I fully agree, and I think that those who have tried the operation will fully agree with Dr. Penrose, that the method of excising through the whole circumference of the bowel, the pile-bearing mucous membrane, and drawing down upon the upper segment, and then attaching this to the lower segment without including the skin, has the advantages, first, of removing all possibility of return of the trouble; and, secondly, as Dr. Penrose has stated, in making a clear, clean, linear incision around the circumference of the bowel. Nearly all of us have seen the immense amount of suffering which the older operations by means of the clamp and ligatures, and even the cautery, have entailed. In the cases of the new operation which I have seen, recovery has been rapid and complete. In one case, that of a woman well advanced in life, upon the day after operation, when I got to the house, I found her comfortably seated in a rocking-chair. The physician who had had the case in charge before the operation had given her freely of some medicine to open the bowels, and on the morning after the operation, without any pain and without any tenesmus, she had a large, well formed motion. In the old method, in which for days the physician was called upon to administer opium, either by suppository or hypoder mically, in large amounts, and in which the patient and the physician both looked forward with dread to the time—five, six, or ten days after the operation—when the bowels were to be opened, is, by this method, entirely obviated.

I have seen, in the few cases which I have watched, no pocketing or trouble about the line of incision. The two freshly-cut surfaces unite very quickly—very much more so, it seems to me, than in mucous surfaces elsewhere. Even when the bowels were moved within twenty-four or thirty-six hours, I was surprised to find that there was no trouble.

It strikes me that the continued suture has advantages over the interrupted. Being introduced and made fast at one point, and then carried out and in around the circumference of the bowel, if catgut be used at the time when union usually occurs, the suture is probably dissolved, and passes away without any trouble; or, if silk be used, by simply introducing the scissors and cutting close to the knot, and giving an easy pull, the whole suture is removed without any pain or bleeding.

I must confess that the operation presents to me by far the best method of removing the pile-bearing membrane when it exists and involves one-half, or more than one-half, the membrane around the circumference of the bowel.

MEDICO-CHIRURGICAL COLLEGE.

CHRONIC OVARITIS.

ASIDE from the reflex physical derangements, both local and general, attending chronic ovaritis, there is usually present a greater degree of emotional disturbance than is found in disease of any of the female genital organs. This is not strange, since it is admitted that the ovaries give to woman, in a great measure, all of her characteristics of mind.

When the inflammatory conditions are unfavorable for recovery, the emotional derangement is often progressive. In the early treatment counter-irritants and alteratives often give good results, especially the administration of small doses of the bichloride of mercury three times a day. But, should the tissues of the organ become destroyed and suppuration take place, removal will alone give relief.—*Godfrey.*

PRIORITY IN TUBERCULOSIS INVESTIGATIONS.

IN an editorial upon this subject of inoculation for tuberculosis, the *Medical Age* reviews Koch's statement at the Tenth International Medical Congress, and quotes Dr. Dixon's proposition as published last October in the *Medical News*. The writer then proceeds to say :

> Commenting on this THE TIMES AND REGISTER assumes that Dr. Dixon's paper first suggested to Koch as well as Grancher the line upon which their researches have been made. This is hardly probable, however, since the paper of the latter was deposited with the Academy of Medicine in November, or in less than a month after Dr. Dixon's announcement, which would afford no opportunity for positive investigation and experimentation ; while as for Koch, as already stated, this is mere assumption based upon no tangible evidence.

We are under obligations to the *Age* for having contributed this weighty evidence in favor of Dixon's claim. The matter stands thus : Last October Dr. Dixon published his paper in the *News*. Copies were at once sent by Dixon to Koch, and to Pasteur, at whose laboratory Dr. Grancher was then engaged ; and the very next month Grancher deposits with the Academy of Medicine his paper, which follows the line of investigation marked out by Dixon. That Grancher was fully capable of appreciating the importance of Dixon's work no one can deny. That a paper bearing directly upon the line of work that was being done at Pasteur's laboratory, and advancing so striking a theory as that of inoculation for tuberculosis, being also a further application of a principle originating with Pasteur himself, should be totally overlooked by that shrewd man and his quick-witted associates, is not a very probable assumption. But that one among them should at once take steps to secure for himself the credit of originating the idea of a foreigner, in a country where priority is so highly valued as it is in France, is not an assumption devoid of reasonability or without precedent.

THE RENAISSANCE IN THERAPEUTICS.

UNDER this title, Kent Spender contributes an article to the *Practitioner*, from which we extract the following :

(1) The analgesics are indicated for pain so acute and sudden as to be dangerous, and relief at any cost is demanded. For less urgent pain opium is the remedy ; also, in incipient inflammations, as in the eye. (2) In rising inflammations, with pain as a subordinate factor, he recommends antimony ; giving mastitis and pityriasis rubra as examples. (3) There are diversities in the action of some medicines, as given in large or in small doses. (4) Drugs with similar action increase each other's efficacy when given together. (5) A mark of the Renaissance is the readiness to drop useless lumber ; phosphorus has gone down since 1874, while salicine is in the ascendant. (6) Goldsmith said that "cautious stupidity is always in the right ;" but timid dosage causes many failures. So chloral is the supreme, sole remedy in delirium tremens ; arsenic is given to children in the same doses as to adults, and belladonna in even larger doses.

We fancy that throughout the article the reader will note the underlying conviction that the Renaissance is best exemplified by the practice of Dr. Kent Spender. Few will agree with all his dicta, and some may be unkind enough to suggest that in unloading lumber he might have included tartar emetic. On this side of the ocean we manage to treat mammary inflammations very satisfactorily without plaguing the woman with antimony when she is enfeebled with childbirth. And while chloral may be the best weapon against delirium tremens in Dr. Spender's armory, we would be very sorry to think the profession had no better resource than drugging with unlimited chloral. He who has learned the value of food, coca, capsicum, and baths will scarcely accept Dr. Spender's valuation of chloral.

Annotations.

BERBERIS AQUIFOLIUM.

THE special indications demanding berberis may be summarized as follows : Long continued gastric and intestinal indigestion, not very severe, but occasionally lighted up by some indiscretion of diet or exposure to inclement weather, or overexertion. The patient has become thin, but not emaciated, and does not suffer much inconvenience from constipation, although there may be slight rectal irritation from hemorrhoids. If the patient be a woman all these symptoms will be more distinct than if a man, and in addition there may be some uterine trouble. This complication is very common about the climacteric, but it in nowise forms a contra-indication to the use of the drug.

A favorite formula with me is the following :

℞.—Fluid extract of berberis aquifolium,
Glycerine . . . . . āā ½ ounce.
Tincture of prickly ash with Jamaica rum . . . . . 4 ounces.
Dose.—A tablespoonful in water after meals.

—Aulde, *Med. News.*

THE MEDICO-CHIRURGICAL HOSPITAL.

THREE weeks ago this hospital appealed to the public for funds to complete the enlargement of its building and refurnish. The sum required is $25,000, and already over $11,000 has been subscribed. The Managers state that their requests have been responded to with an alacrity and a kindly feeling which is very gratifying. The strength of this institution lies in the good work done in its wards; the best friends being those who have entered as patients. This is a pretty good world, and there are few hearts that do not sympathize with the true spirit of charity, which does not limit its benefactions to those objects that offer the possibility of return, but reaches out a helping hand to the poor, the lowly, those who have neither money, nor friends, nor any other claim but the greatness of their need. Philadelphia is full of noble charities; but among them there is none nobler than this hospital. It appears to have the power of attracting good women to its aid, and we doubt if the Board of Managers and those who have assisted them can be equaled in the million residents of Philadelphia for energy, ability, and kindly interest in their charges. It may interest those who attended the brilliant fair given last winter at the Academy of Music by this organization, to know that that effort will be probably eclipsed by a still greater during the coming winter.

THE CATHA EDULIS.

IN that part of Africa which lies between the fifteenth degree of north and the thirtieth degree of south latitude, but more particularly in Arabia and Abyssinia, there grows in abundance a small shrub with hard lanceolated leaves, olive-green in color, harsh and astringent in taste, of which some samples have been acclimatized in the gardens on the coast of the Mediterranean and in the experimental garden in Algiers, the capital of Algeria. To this shrub, which the Arabs call Kat or Qat, Forskall, a Swedish botanist who discovered it in the last century, gave the scientific name of Catha Edulis. It has for ages past been used in Arabia and Abyssinia as a stimulant and as a temporary substitute for food, and now for some months it has been utilized in therapeutics as a succedaneum for coffee, mate, and kola. Its physiological effects have been ascertained by several experiments. A seamstress, for example, who took a small dose of extract of Catha, was able easily to work three times as long as usual without intermission; a medical student who chewed a handful of Catha leaves remained awake all night; and another young student, who was on the point of breaking down, used Catha for four days and found his mental and physical strength restored. The therapeutic properties of this plant will no doubt be made the subject of scientific study.—Cartaz, in *La Nature*.

UP to the time of writing the situation at Jefferson remains unsettled. Professor Bartholow declined to take a vacation, and the Trustees have declared his chair vacant, and will elect his successor on Monday. While Dr. Hare is most frequently spoken of as the chosen successor, many urge Drs. S. Solis-Cohen, T. J. Mays, Frank Woodbury; and Dr. Potter, of San Francisco, is also mentioned prominently.

The action of the students, though prompted by the generous feeling of affection to their old instructor, was ill-advised in the extreme. Nobody has the interests of Jefferson at heart more than the Faculty and Trustees, and they may certainly be credited with having very good reasons for displacing as strong a man as Dr. Bartholow. It is not always best for the interests of either party that these reasons should be made public; and serious injury might have resulted had the students persisted in their action. As a graduate and well-wisher of Jefferson we trust that the result will be favorable to her best interests.

Of the gentlemen named, Dr. Cohen would be, perhaps, best fitted to deal with an unruly class. He has won an honorable place among Philadelphia physicians, and displayed talent as a teacher.

Dr. Woodbury would bring to the chair a ripe professional scholarship, with considerable practical experience as a teacher. As a clinician he has no superior.

Dr. Potter has made a very favorable impression with his book on therapeutics, which has been adopted as a text-book in many colleges.

Letters to the Editor.

IN the list of the Medical College Announcements (for 1890 and 1891), published in THE TIMES AND REGISTER, I do not see the name of the Trinity University, of Bennington, Vermont, (department of Medicine and Surgery).

Question: Has this university discontinued its teachings? or has it ever had an existence, as I am taught to believe it has? Will you please (if you can) answer these questions? READER.

SALT LAKE CITY, UTAH.

[The institution named is registered as fraudulent in the last report of the Illinois State Board of Health. —ED. T. & R.]

Book Notices.

ESSENTIALS OF THE DISEASES OF CHILDREN. By WILLIAM M. POWELL, M.D. Philadelphia: W. B. Saunders 913 Walnut street, 1890. Cloth, pp. 222. Price, $1.00.

This is somewhat better in all respects than Morris' book. The author has felt it a duty to follow Starr closely. The numerous prescriptions would have been improved by following the pharmacopœia more closely. Where is the authority for capitalizing adjectives derived from common nouns?

Pamphlets.

Diagnosis and Operative Treatment of Gunshot Wounds of the Stomach and Intestines. By N. Senn, M D., Ph.D., of Milwaukee, Wis. Read by invitation in the Surgical Section of the Tenth International Medical Congress, August 8, 1890.

Vaginal Tamponage, an Improved and Simplified Process for Rendering Continuous Support to the Organs composing the Female Generative Tract. By Charles C. Fredigké, M.D. With four zinc etchings. Chicago: Press of R. R. McCabe & Co., 1890.

De la Laryngite Tuberculeuse, a Forme Scléreuse et Végétante. Par MM. le Dr. Gouguenheim et J. Glover. Extrait des *Annales des Maladies de l'Oreille et du Larynx*. Paris: G. Masson, Éditeur.

Proceedings of the National Conference of State Boards of Health, at the Seventh Annual Meeting, held at Nashville, Tenn., May 19–20, 1890. Published for the State Board of Health of Pennsylvania. Columbus, Ohio: Myers Bros., Printers and Publishers, 1890.

The Medical Digest.

FOR NEURALGIA.—Bidwell (*K. C. Med. Index*) speaks highly of the combination of salol and phenacetine, 2½ gr. each.

CAUSTIC FOR NÆVI, TUBERCULAR GROWTHS, ETC.—

℞.—Sodii ethylati . . . . . ʒj.
Alcohol . . . . . ʒj.
M.—S. Apply with care.

—Richardson.

FOR TYPHOID FEVER.—

℞.—Cupri arsenitis . . . . . gr. $\frac{6}{100}$.
Morphinæ sulph. . . . . gr. ss.
Glycerini,
Aquæ dest. . . . . āā ʒij.
M.—S. A teaspoonful every hour.

—Moore, *N. W. Lancet.*

DIURETIC AND DRASTIC.—

℞.—Pulv. scillæ,
Pulv. scammonii,
Pulv. digitalis . . . . . āā ʒj.
M.—et in pil. No. lx, divide.

—Laramee, *L'Union Méd. du Canada.*

CHLORALAMID may be given as follows:

℞.—Chloralamid . . . . . gr. xiv.
Acid. hydrochlorici dil. . . . . gtt. vj.
Syr. rubi idæi . . . . . ʒij.
Aquæ . . . . . ad ʒij.
M.—S. To be taken in one or two doses.

—Steele, *K. C. Med. Index.*

FOR ECZEMA AND ALL SQUAMOUS AND VESICULAR ERUPTIONS.—

℞.—Plumbi oxid. vel carb. . . . . gr. xx.
Hydrargyri oxid. rub. . . . . gr. x.
Ol. palmæ purif.,
Adipis benzoati . . . . . āā ʒss.
Creasoti . . . . . ♏vj.—M.

—Startin.

COMPOUND BISMUTH LOTION.—

℞.—Bismuth subnit.,
Zinci oxid.,
Tinct. camphoræ,
Glycerini . . . . . āā ʒss.
Aquæ . . . . . q. s., ad ℈j.
M.—S. For local use, in irritable, vesicular, and sebaceous skin affections.

—Startin.

DIURETIC.—

℞.—Tinct. digitalis . . . . . ʒijss.
Potassii iodid. . . . . ʒij.
Tinct. opii comp. . . . . ʒss.
Syr. pruni Virg. . . . . ʒij.
Syr. scillæ . . . . . ʒj.
M.—S. A teaspoonful every four hours.

—Laramee, *L'Union Méd. du Canada.*

FERRUGINOUS PILLS.—

℞.—Ext. cinchonæ,
Ext. gentianæ,
Ext. rhei,
Ferri et potassæ tart. . . . . āā gr. lxxv.
Ext. nucis vomicæ . . . . . gr. vijss.
Ol. anisi . . . . . gtt. v.
Glycerini, q. s.
M.—et in pil. No. c, divide.
S. Two pills before each meal.

—Huchard, *Le Bull. Méd.*

MIXTURE FOR FETID EXHALATION FROM THE MOUTH.—

℞.—Bicarb. of soda,
Saccharine . . . . . āā ʒj.
Salicylic acid . . . . . ʒj.
Proof spirit . . . . . ʒvj.
A teaspoonful in a glass of water to rinse the mouth.

—*Medical Press.*

OINTMENT FOR FISSURES AND ECZEMA OF THE NARES.—

℞.—White precipitate,
Boric acid . . . . . āā ʒj.
Oxide of zinc . . . . . ʒj.
Acetate of lead . . . . . grs. v.
Vaseline . . . . . ʒj.
F.S.A.

—*Medical Press.*

OINTMENT FOR PRURIGO.—

℞.—Resorcine . . . . . ʒjs.
Sulphur . . . . . ʒj.
Phenic acid,
Salicylic acid . . . . . āā 10 grs.
Chloral . . . . . ʒj.
Vaseline . . . . . ℥iss.
F.S.A.

—*Medical Press.*

FOR GASTRIC CANCER.—

1. ℞.—Bismuth salicylat.,
Magnesiæ (English),
Sodii bicarb. . . . . āā ʒijss.
M.—Divide in thirty cachets.

2. ℞.—Bismuth salicylat.,
Beta-naphthol,
Carbonis . . . . . āā ʒijss.
M.—Divide in thirty cachets.

3. ℞.—Bismuth salicylat.,
Salolis,
Sodii bicarb. . . . . āā ʒijss.
M.—Divide in thirty cachets.

These are to be taken, a cachet before each meal, to secure intestinal antisepsis.

—Dujardin-Beaumetz, *Le Bull. Méd.*

FOR HAY FEVER.—

℞.—Zinci valerianat . . . . . gr. j.
Pil. asafœtidæ comp. . . . . gr. ij.
M.—S. One or two pills to be taken two or three times daily. (For neurasthenia.)

—Sir Morell Mackenzie.

℞.—Acid. chromici cryst. . . . . gr. $\frac{1}{16}$—$\frac{1}{4}$.
Aquæ destillat. . . . . ʒj.
M.—S. To be sprayed into the nose (diluted with equal quantity of boiling water) for two or three minutes, several times daily. (For paroxysmal sneezing and rhinorrhœa.)

—Macdonald.

℞.—Glycerini acid. carbolici . . . . . ʒj.
Quininæ hydrochlor. . . . . ʒj.
M.—S. Dissolve by heat, and add $\frac{1}{2000}$ part of bichloride mercury. Apply cautiously to nasal mucosa every two to three days.

—Sir Andrew Clark.

PILOCARPINE IN RENAL AND CARDIAC ŒDEMA.—Two medical men of high standing warmly recommend injections of pilocarpine in œdema of renal or cardiac origin, and if prolonged they cause it to disappear with absolute certainty. The injections are given once a day at the dose of ¼ of a gr. of the hydrochlorate of pilocarpine. In a few days it can be raised to ½ gr., and finally 1 gr. can be given. At the beginning the injections produce symptoms of poisoning resembling those of tobacco (nausea, vomit-

ing, diarrhœa, cold perspiration), but these symptoms are never grave, and soon cease. The patients get so accustomed to the pilocarpine that they complain when it is suspended suddenly of headache and malaise. Provided that the doses are increased gradually the treatment can be applied without fear, even in cases of valvular disease, and in spite of vomiting and hæmoptisis.—*Medical Press.*

Application of Mineral Acids in Necrosis.—According to Dr. Ole Bull, who writes in a Norwegian medical journal, the suggestion of an English surgeon to employ sulphuric acid containing a certain amount of sulphurous acid to loosen necrosed portions of bone is not altogether good, inasmuch as sulphuric acid forms sulphate of calcium, which is insoluble and opaque, and so prevents the acid from acting on the deeper layers, besides obstructing the view. He finds, however, that some of the other mineral acids act very much more satisfactorily. After a good many trials he has come to the conclusion that the most suitable application is a 4 per cent. solution of hydrochloric acid, which he has used very successfully for necrosis and caries of the temporal bone. This forms a soluble salt of lime, and is well tolerated by the external meatus, and even by the cavity of the tympanum. In cases where polypi had been removed by means of galvano-cautery or by chromic acid, treatment of the stump by hydrochloric acid was very successful, but it was necessary to continue the applications for about three months.—*Lancet.*

The Succinimide of Mercury in Syphilis.—Dr. Selenew, who has made comparative trials of the advantages of several mercurial salts for hypodermic use in the skin and syphilitic clinic at Kieff, which is under the direction of Prof. Stukovenkow, has recently obtained considerable success by using the succinimide, a salt which was originally recommended for the purpose by Dr. Vollert and was used in Prof. Wolff's syphilitic clinic in Strassburg two years ago in doses of about one-sixth of a grain. Dr. Selenew employed larger doses (one-quarter to one-third of a grain) in a solution of the strength of 1 per cent. The injections, of which nearly a thousand were given altogether, were usually made into the cellular tissue of the back or buttocks. In some cases a daily injection for twenty-four days sufficed to cause all the syphilitic appearances to disappear; in most of the cases the treatment had to be carried on for about a month, and in one case for forty days. Thirty-three patients in all were treated. In six the gums became affected. In only one was the pain at the seat of puncture at all severe; usually there was no pain at all. In one case there was abdominal pain and diarrhœa, which lasted for five days. Out of twenty-four cases of primary syphilis, which remained under observation for seven months, only three developed secondary symptoms, and one of these was that of a man addicted to drink. Comparing the results in preventing secondary symptoms with those obtained by the injection of other mercurial preparations, the succinimide appears to be about as efficacious as the yellow oxide, and very much more so than the alaninate, the salicylate, or the so-called gray oil. Dr. Selenew looks upon the succinimide as a mild and valuable preparation, which may be very useful in primary and secondary cases of no great severity, especially in women and children, because of its slight tendency to cause local irritation. In severe cases a more active preparation, as the yellow oxide, the perchloride, the salicylate, or the oxybenzoate, should be preferred.—*Lancet.*

Anodyne Effects of Electric Light.—Stein, of Moscow, records (*Meditzinskoïe Obozrenië*) a series of fourteen cases of various painful affections in which he used electric light as an anodyne, with almost "magical" results. The apparatus (devised by himself) used for the purpose consisted of a small-sized (three or four volts) incandescent electric lamp, furnished with a suitable handle and a funnel-shaped reflector, varying from 3.5 to 6 centimetres in length and from 2 to 3 in the longest diameter, the lamp being fixed within the reflector. In cases where the head or neck was affected, the illumination (the reflector being applied directly to the painful area) lasted from ten to fifteen seconds; in other regions of the body from one to five minutes, or even longer, until the patient began to complain of intense heat. The anodyne effects are said to have been invariably most striking. A woman, suffering from very obstinate intercostal neuralgia, after a single sitting (a series of illuminations, each of a few seconds' duration) was completely and permanently freed from pain. The same result was obtained in another patient suffering from intense rheumatic pains about the shoulder. In a woman, aged fifty, suffering from agonizing lumbago, four sittings of five minutes' duration twice a day proved equally successful. In another patient, a nervous woman who had had excruciating pain about the right foot and ankle causing lameness, two illuminations of five minutes' duration caused complete cessation of the symptoms. In a patient suffering from pulmonary and laryngeal tuberculosis, and most troublesome, almost incessant, cough, in whom even morphine in the daily dose of one grain had afforded but trifling relief, from ten to fifteenth seconds' illumination of the larynx and both sides of the neck externally, repeated every other day, reduced the paroxysms of coughing to two or three in the twenty-four hours.—*Brit. Med. Jour.*

Successful Suture of Tendons Eleven Weeks After the Injury.—John L——, aged forty, came to me on December 13, 1889, with the following history. Eight weeks previously, while engaged in trimming rose trees, the knife he was using slipped and inflicted a transverse wound on the outer side of the left wrist, one inch above the thumb. The wound was allowed to heal by granulation, no advice being obtained until it was found that the thumb could not be moved voluntarily, at which time the patient was comforted by being told that "some nerves were cut across, and that voluntary movement would return in the course of time." On December 13, 1889, the left hand was of little use, as the thumb was flexed into the palm and adducted, so that the patient was unable to pick up a book or to hold anything unless the thumb was first lifted up and the article to be held placed between it and the hand. Any variety of passive movement was possible, but the only active movement which remained was extension of the terminal phalanx, the thumb being rendered motionless owing to the unopposed action of the flexor longus pollicis, adductor pollicis, and the flexor brevis pollicis. At the base of the first metacarpal bone, and one inch above it, there was a transverse scar an inch long, on the outer surface of the left wrist. Just below this the distal ends of the tendons of extensor primi internodii pollicis and extensor ossis metacarpi pollicis could be easily felt, but the position of the proximal ends could only be indistinctly made out five inches off on the back of the fore-arm. On January 8, 1890, eleven weeks after the accident, the patient being under chloroform and an Esmarch's bandage

being on the arm, an incision was made from the site of the distal ends of the tendons to the supposed position of the proximal ends. The distal ends were found at once, and it was then discovered that the synovial sheath was blocked at the site of the scar for three quarters of an inch, by a mass of connective tissue. This was cut through and the sheath slit up until the proximal ends of the tendons were found. All four ends were smoothly rounded off, and no adhesions had been formed. Unfortunately, the ends of the tendons were five inches apart, and it was found to be impossible to bring them nearer together than three-quarters of an inch. However, the ends were cut off, and they were then stitched together with two catgut sutures each. One or two small vessels were tied, and the wound was closed by silk sutures without any drainage, the tourniquet not being removed until a wool dressing had been firmly applied, after which a special splint was put on in such a way as to keep the thumb fully extended. The wound healed by first intention. On Friday, June 27, about six months after the operation, the patient was shown at a meeting of the Worcestershire and Herefordshire branch of the British Medical Association, having all the active and passive movement of the thumb perfect.

—Gostling, in *Lancet.*

A NEW OPERATION FOR STRICTURE OF THE RECTUM.—Mrs. B., aged thirty-two, giving history of syphilis, with a subsequent rectal stricture and fistula in ano. The symptoms of stricture, growing worse each month and not having more than one operation on bowels a week, brought the patient under examination July 28, 1890. After inducing anæsthesia examination, revealed a fistulous tract from superficial sphincter opening one and one half inches from anus, also flaps or folds of mucous tissue around the anus; within were infiltration and thickening of mucous and submucous structure, and about three inches above the anus an annular stricture almost occluding the rectum.

After dividing the fistula and superficial sphincter, a pair of uterine dressing forceps were introduced through the stricture, by means of which sufficient dilation was made to introduce a probe pointed bistoury; two incisions were then made well dividing the stricture bi-laterally. Pratt's large dilating speculum was then introduced dilating the rectum to its full capacity, being frequently turned in various directions for the purpose of thoroughly using a douche of warm carbolized water, and curette and silver nitrate to all suspicious pockets.

Keeping up these antiseptic precautions for about twenty minutes, and the speculum remaining *in situ* paralyzing all muscular action, no difficulty was experienced in bringing down the stricture with a tenaculum and securing with an Emmett needle armed with catgut suture or loop; the mucous membrane from the stricture to the anus falling in folds and protruding from the anus like external pile tumors, an assistant then holding the stricture in position by means of the loop, the posterior folds of mucous tissue were removed with tenaculum and scissors; then making an incision half way around the anus posteriorly and removing corresponding cicatricial tissue in the stricture, the two surfaces thus denuded were securely brought together with catgut sutures. Nothing was at the time done with the protrusion of mucous folds on the anterior surface.

The usual dry dressing was then applied, and patient taking an opiate was put to bed. No suffering or inconvenience followed. The bowels moved each day, and on the eighth day patient returned, when, with the aid of sol. cocaine, the anterior folds left protruding on the day of the operation were snipped off with tenaculum and scissors. Entire recovery on fourteenth day from first operation. No trouble has arisen since.

Note the following suggestions, which will improve the plan of procedure:

1. Don't divide stricture before it has been brought down to the anus, and do not allow it to return after dividing.

2. Don't bring the stricture down with the tenaculum, but use hæmostatic forceps to avoid laceration and puncturing.

3. Don't paralyze with speculum; use fingers to avoid rupturing rectum at site of stricture, which accident might cause peritoneal complication.

4. If stricture cannot be brought down to anus, denude and stitch to muscle.

—Thompson, *Jour. Am. Med. Assoc.*

Medical News and Miscellany.

THE Des Moines Free Dispensary has been abandoned.

DR. J. W. KESLER, of Honesdale, Consul at Ostend, Belgium, is home for a short visit.

DR. L. WEBSTER FOX has returned to his Philadelphia home from an extended European trip.

DR. ECCLESTON gave a lecture, Wednesday, October 22, in St. Luke's Parish Building, Germantown, Pa.

DR. HENRY ECKROYD, of Newport, R. I., was married on Thursday to Miss Ashbridge, of Chester county.

AMONG the guests at the Bi-Centennial Executive Club's eighth annual dinner was Dr. J. J. Levick, of Philadelphia.

DR. WILLIAM E. ASHTON, last week, successfully performed the Cæsarean operation upon a patient in the Philadelphia Hospital.

JEFFERSON'S students threaten to make things hot for Bartholow's successor. If they do, the latter will not find his path strewn with roses.

THE biologist of Johns Hopkins reports that the Maryland oyster will have gone to join the buffalo as an extinct species in the space of three years.

TENNESSEE reports typhoid fever in 19 counties; whooping cough in 12; diphtheria in 7; scarlatina in 7; measles in 3; Shelby county reports all five.

DR. J. J. GRIFFITH, of Manayunk, has consented to bear the standard of the Prohibitionists in the legislative battle. Sorry so good a man cannot win.

PRINCIPAL FETTERS, of the Normal School, has endowed a bed in the Medico-Chirurgical Hospital, in memory of his deceased wife. The girls of the school furnished a room some time ago in this hospital in Mrs. Fetters' name.

A NURSE says that the great danger to the young members of her craft is being made love to, while the older are apt to take to drink.

The old, old story. When Theseus deserted Ariadne, Bacchus consoled her.

A PHILADELPHIA lady, thinking that nature had not quite done her full duty by her, bought a box of "Circassian Face Ointment," which she applied to her face. The consequences were so grave that she has entered suit against the druggist, claiming damages to the amount of $5,000.

CHICAGO CHILDREN'S HOSPITAL.—A meeting of the Board of Directors of the Chicago Children's Hospital and Mission to the Destitute was held at the Sherman House. It was determined, as soon as a house could be rented, to go forward with this commendable undertaking, and provide a home for the needy class of disabled and infirm children.

THE *Country Doctor* proposes to give each of its subscribers a free ticket for a trip around the world by the Chicago balloon line, as soon as the latter gets into working order. The subscription price of our contemporary (one dollar) can be sent at once; and we can assure our readers that no one thus sending will be *left*; though he need not pack his grip in a hurry, as the line will not be open this year.

REMARKABLE success has been attained by Prof. Ahn, of Breslau, in applying photography to fix the indications of different diseases of the eye. Another contribution to one of the newest departments of science is Prof. Fischer's photographs of cultivation of luminous bacteria, which were photographed by their own light—the views giving evidence of the constant movement in which the tiny organisms are unceasingly engaged.

NEARLY a million emigrants leave Europe yearly to seek new homes. Of these the Norse, German, British, and Irish go mainly to the United States. Next in popularity comes Argentina, where Italians and Spaniards resort. Brazil comes third. Australia exemplifies the difference between an independent country and a colony. She only attracts an annual immigration of 60,000, while she already furnishes a supply of her citizens to build up other lands, in spite of her boundless wealth of undeveloped territory.

THE November number of *The Sanitarian*, forthcoming, will begin the publication of the Transactions of the American Climatological Association, held at Denver, Col., September 2, 3 and 4, 1890. All new subscribers for *The Sanitarian* for 1891, sending their subscriptions before the 15th of November, will be supplied with the November and December numbers gratis. Subscription, $4.00 a year, in advance. All correspondence should be addressed to the editor, A. N. Bell, M.D., 113a Second Place, Brooklyn, N. Y.

AT the meeting of the American Pharmaceutical Association, in September, at Old Point Comfort, Va., Oscar Oldberg read a paper upon The Constitutional Obligation of Congress Regarding Weights and Measures.

Accompanying this paper the writer submitted the following resolutions:

WHEREAS, The Constitution of the United States imposes upon Congress the duty of establishing fixed standards of weights and measures for the use of the people; and

WHEREAS The customary weights and measures in use in the United States are arbitrary, unsystematic, inconvenient, and indefinite, being governed partly by English law, partly by tradition, and partly by chance; and

WHEREAS, No laws of the United States exist establishing a national system of weights and measures or fixing the values of the customary units; therefore be it

Resolved, by the American Pharmaceutical Association, That Congress be and is hereby respectfully requested to consider, without unnecessary delay, the importance of legislation upon this suject; and further

Resolved, That it is the sense of this Association that it would be worthy the dignity of the American nation to celebrate the four hundredth anniversary of the discovery of America by the adoption of the decimal system of weights and measures in all governmental transactions and for purposes of foreign and inter-state commerce, to take effect on the date of the landing of Christopher Columbus on this continent, and

Resolved, That copies of these preambles and resolutions be forwarded by the Secretary of this Association to the Speaker of the House of Representatives of the United States, to the Chairman of the Committee on Coinage, Weights and Measures of the House of Representatives, and to the Superintendent of the Bureau of Weights and Measures.

These resolutions were adopted, and a committee appointed to urge the attention of Congress to the matter.

THE *Texas Health Journal*—he of the excited imagination that sees hydra-headed monsters clawing at his scalp—proposes a new medical college in Texas on a new and original plan. There are to be ten professors; eight regular, one homœopath, and one eclectic. They are to be appointed by the State Medical Association, and to constitute a State Board of Health. This college is to have supreme control of the practitioners of medicine in Texas. The college is to be supported by the State, and charge no fees. It also records deaths and births; but it is not stated whether it collects garbage or not.

IT is not generally known that the Irish member of Parliament, John Dillon, now on his way to America, is a doctor by profession. Previous to the land agitation he was demonstrator of anatomy at the Ledwich School of Medicine, in Dublin, and distinguished himself by making some discoveries which have proved of importance to science. Mr. Dillon has visited the United States several times. He is loved in Ireland with a peculiar love; it is akin to the feelings of a mother for her favorite child. He, on the other hand, always speaks of the Irish as "My people." Mr. Dillon entered the present Irish movement because he took in the spirit of Irish Nationalism with his blood, and because by his nature he was bound to be an enthusiast in some cause.—*N. Y. Telegram.*

POLICE SURGEON ANDREWS is not the only person who mourns the loss of an overcoat through the visit of a sleek young thief. Dr. Bradfield, 1236 Spring Garden street, lost two overcoats and a pair of opera glasses. The doctor recovered the opera glasses at a pawnbroker's.

Druggist Ashmead, Eleventh and Walnut streets, lost a coat, as also did another physician and a dentist. The thief is described as being of medium size, dark complexion, has a small black mustache and small side whiskers, is well dressed, including patent leather shoes.

The sneak thief who visited the office of the *Medical Press* Company, on Saturday afternoon, October 25, was light in complexion, and differed in many respects from the above description. It is probable that several of these gentry are working doctors' offices, and warnings should be given against people who come in to wait in the office.

AERATING MILK.—The New York Dairy Commission says that milk can be sent further and will be in a better state for use when aerated down to the temperature of the atmosphere than when chilled and sent on ice. The process is very simple, and consists in allowing the milk to run from one receptacle to another in fine streams, so as to come thoroughly in contact with pure air. It should not be done in the

barn or stable, but out of doors where the air is purest. If nothing better is at hand, let it run through an old colander two or three times. A better arrangement is a set of perforated pans, one above the other, through which the milk may run in fine streams. It is held that tyrotoxicon poison is generated in cream for the want of proper aeration, and that unaerated milk is the great enemy of infants and the great cause of cholera infantum.

MEDICO-CHIRURGICAL COLLEGE NOTES.—The question as to the advisability of having the lectures of some of the professors stenographed and type-written is now being agitated by the classes of the Medico-Chirurgical College. Some argue that the student can thus pay more strict attention to the lectures, as he often loses a good point while engaged in jotting down one already made, and by having a type-written copy of the lectures given him the following day he will be more likely to refresh his mind upon the most important and essential parts of the lectures, which he is not so apt to do, when to do so turning the leaves of ponderous text-books is made necessary. Others argue that it will tend to make students cut lectures; but if each professor calls the roll, that tendency will receive a wholesome check.

Prof. Anders takes two sections of the senior class through the wards of Blockley every week. The abundance and variety of cases to be seen at this institution offers a rare opportunity for bedside instruction.

Dr. Wm. B. Stewart, of the class of '90, conducts the senior recitation in Practice. His method of conducting the recitation is highly appreciated by the students. They are not asked to give only the causation, pathology and symptoms of disease, but are required to place upon the blackboard a correctly written prescription in addition to an oral statement of the general line of treatment.

The following new assistants at the surgical clinics of Profs. Goodman and Laplace have been appointed: On Prof. Goodman's clinic—Charles J. Stein, Gordon L. Harker, W. N. Watson. On Prof. Laplace's clinic—S. Montegut, August Trapold. On Prof. Montgomery's gynecological clinic F. H Maier and Harry L. Clayton have been appointed assistants.

Professor Shoemaker is giving the senior class a very thorough and practical instruction in electro therapeutics. Through the kindness of Mr. Yarnall he has had placed in the clinical amphitheater a large Waite & Bartlett static machine, which he uses for the practical demonstration of the efficacy of the static current in various diseased conditions.

The senior class will be divided into sections for practical work in gynecology, under the charge of Dr. Early.

FOURTEEN WAYS TO HELP A DOCTOR.—1. When it is necessary to send for medical service, do so, if possible, before the physician goes out for his morning round of visits. Do not delay until he has come in tired, having possibly been in the very street in which you live.

2. If possible, send a note stating which member of the family is ill, and briefly detailing the symptoms, and giving the doctor an idea with regard to the case.

3. If unable for any cause to send a note, at least try to send some intelligent messenger who can write out the call in full on the doctor's slate.

4. In case of poisoning, be sure to send word, if known, what poison has been taken, as the doctor may then be able to bring with him an antidote in time to save life.

5. When the doctor comes, let some one person who is familiar with the case give him the details with regard to it; too many informants create confusion.

6. Do not discuss the case before the patient.

7. Have a pencil and slip of paper, and write down at once the instructions received.

8. *Try to be exactly accurate in statements.*

9. Do not have children or dogs in the sick room during the doctor's visit, as the children and dogs will divert his attention.

10. Carry out faithfully and exactly the orders given by the medical man.

11. "Trust me not at all or all in all," should be the doctor's motto.

12. When consulting a medical man in his own house, do so during his office hours. Do not go just at the time he takes his meals.

13. Finish the professional interview with him in his consulting room, and do not continue detailing symptoms in the hall when being shown out.

14. Bear in mind the comfort of the doctor, and when the conditions suggest, do not forget to give him a cup of cold water, or of hot coffee, or a plate of soup, as the case may be.

You will give him renewed in piration for his work.

[If the contents of the journal from which the above is taken are all like this, its name should be changed from *Good Housekeeping* to *Good Sense.*]

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from October 3, 1890, to October 13, 1890.

By direction of the Secretary of War, First Lieutenant Allen M. Smith, Assistant-Surgeon, is relieved from duty at Fort Snelling, Minn., and will report in person to the commanding officer, Fort Assinniboine, Mont., for duty at that station, relieving Assistant Surgeon Paul Shillock. Lieutenant Shillock, upon being relieved, will report in person to the commanding officer, Fort Custer, Mont., for duty at that station, relieving Captain William R. Hall, Assistant-Surgeon. Captain Hall, upon being relieved by Lieutenant Shillock, will report in person to the commanding officer, Fort Schuyler, New York, for duty at that station, relieving Captain Norton Strong, Assistant-Surgeon. Captain Strong, on being relieved by Captain Hall, will report in person to the commanding officer at Fort Meade, S. Dak., for duty at that station. S. O. 232, par. 8, A. G. O., Washington, D. C., October 3, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending October 18, 1890.

BRIGHT, GEORGE A., Surgeon. Detached from temporary duty at the Naval Academy, and placed on waiting orders.

AYRES, J. G., Surgeon. Detached from temporary duty at the Naval Academy, and placed on waiting orders.

LUMSDEN, GEORGE P., Passed Assistant-Surgeon. Detached from U. S. S. "Boston," and granted three months' leave.

AUZAL, E. W., Passed Assistant-Surgeon. Detached from the Naval Academy, and ordered to U. S. S. "Boston"

SMITH, HOWARD, Surgeon. Ordered to appear before the Retiring Board at Mare Island, Cal.

The Times and Register.

SUPPLEMENTARY REPORT TO A CASE OF CHOLECYSTOTOMY.[1]

BY RUFUS B. HALL, M.D.,
CINCINNATI.

I TAKE this, the first opportunity, at the first meeting of this society after the summer vacation, to put the remainder of the history of this very interesting case on record. When I prepared the report of the case for the State Society meeting, the patient was rapidly improving, with every prospect of a permanent recovery. I did not have an opportunity to present my paper at that meeting, from the fact that it was a volunteer paper, and the regular programme occupied all the time. I read the paper before this society June 10, and it was published in the Philadelphia TIMES AND REGISTER soon afterwards.

The operation was made April 13, 1890, at 10 A. M. (For details of the operation I will refer the reader to the published report.) Very briefly I will say: After making an incision through the abdominal wall we came upon the distended gall-bladder, which was aspirated and six ounces of gall removed. I then incised the gall-bladder and removed four gall-stones, which were lying loose in the bladder. On searching for the cause of the obstruction it was easily found, and proved to be a stone impacted in the common duct, which was removed without difficulty. After probing with metal probes, and then passing a No. 7 English male bougie through the common duct into the intestine and detecting no obstruction, the gall-bladder was stitched to the upper end of the abdominal incision and the abdominal wound closed in the ordinary way.

Thirty hours after the completion of the operation it was plainly evident that the patient could not long survive if the hemorrhage, which had existed from the time of the operation, could not be controlled. After gaining the consent of the husband, I opened the abdomen to search for the bleeding point; this proved to be from the edges of the abdominal incision; there was no bleeding vessel, but oozing from every portion of the wound. This was controlled, and she went through the operation as well as the first. On the third day she retained liquid food, and on the fifth day she had a ravenous appetite. The stools showed the presence of bile from the first movement, which was on the fourth day.

On May 4, twenty-one days after the operation, the sinus where the drainage-tube was placed in the gall-bladder was closed, and remained so for more than a *month*, without the least inconvenience, pain or tenderness in the region of the scar or gall-bladder. The cholæmia had entirely disappeared, and the stools returned to their natural color within a few days after the operation, showing the presence of bile in the intestine, and remained the natural color for more than *two months*' time. She gained in strength and flesh every day, and was able to go up and down stairs and to superintend her household duties up to about the middle of June, when she commenced to suffer from an uneasy sensation in the region of the gall bladder. She lost her appetite; the tongue became coated; the stools, which had before been the natural color, now became lighter and finally putty color. In a few days after she commenced to complain there was a perceptible enlargement in the region of the gall-bladder. As this increased she suffered more pain, became restless, appetite almost wholly failed, and she lost flesh rapidly. Within a week after she commenced to complain there was an enlargement in the region of the gall-bladder the size of a closed hand, with every

[1] A paper read before the Cincinnati Medical Society, September 9, 1890, also read by title at the Ohio State Medical Society, June 4, 5 and 6, 1890.

indication that she was again suffering with an obstruction of the common bile duct. The enlargement increased and commenced to bulge at the site where the drainage tube had been placed. This was incised by her physician, Dr. Stevens, and a pint or more of bile discharged. This gave her relief, and through the wound there was a thorough search made for the cause of the obstruction, but no stone could be found. After repeated examinations it was believed that the cause of the obstruction was due to a contraction of duct at the point where the stone was impacted at the time of the operation. Up to the time of her death the external wound closed about a half dozen times for a few days at a time. As soon as the wound would close the stools showed the *psesence of bile*, and the patient felt some better until the gall-bladder became greatly distended, when she would suffer from the pressure until the adhesions gave way or. it was laid open. These facts led us to more firmly believe that the obstruction in the common duct was due to a stricture, and not an impacted stone. After the gall-bladder discharged externally she felt better because relieved from pressure, but worse because deprived of bile. The last three weeks of her life the gall-bladder remained open externally and discharged freely. She died of exhaustion on the 24th day of August, four months and eleven days after the operation.

The autopsy was made the following day by Dr. E. S. Stevens. Present: Drs. W. E. Shaw and C. B. Van Meter. The stone here presented was found in the common duct. The stone, as you will see, is about the same size and shape as those removed at the operation, and has no facets upon it.

A very interesting question in the history of this case is, Where was this stone at the time of the operation? I think it was in the hepatic duct. My reason for believing that the stone found at the autopsy was in the hepatic duct at the time of the operation is the fact that I am certain it was not in the gall-bladder, cystic or common duct, and the known fact that stones do form in the *hepatic duct*. After removing the stones from the gall-bladder and the one from the common duct at the time of the operation, after probing the duct I passed a No. 7 English male bougie through the ducts into the intestine, as the physicians witnessing the operation will readily recall. After the operation, with the gall-bladder attached to the abdominal wall, a stone in the hepatic duct, in its descent the most direct course would be into the common duct, particularly when we remember that this was markedly dilated above the point where the stone had been impacted. Again, the subsequent history after the operation goes to prove that the common duct was pervious for more than *two months* after the operation.

Another question naturally comes up, Why did we not make a second operation? This is an important one, which I will try to answer and give you my reasons for not operating.

The whole history of the case after the operation was one that would indicate stricture, and not an obstruction from a stone. When we recall the fact that the patient had an impacted gall stone in the common duct for more than nine weeks before the operation, which probably caused ulceration at the point of impaction, it would not be an unreasonable thing to believe that the obstruction was due to stricture of the duct at that point; particularly when we recall the fact that at all times when the external opening to the gall-bladder was closed the stools showed the *presence of bile at once*, just as we would expect it to do in a case of *stricture*, and not as we would expect it to do in a case of impacted stone. This, and the fact that we were unable to find a stone by careful and repeated examination, is what we took for fair evidence to found our diagnosis upon. Granting, then, that we had an organic obstruction in the duct near the intestine, I could see but one thing to be gained by an operation, and that would be an anastomosis between the gall-bladder and the intestine. This was carefully and fully considered by the physicians and family, but the patient had lost strength so rapidly after the relapse that any operative interference seemed like a necessarily fatal procedure. Again, the family were not favorably inclined towards an operation unless we could promise definite results, therefore an operation was not urged. If we had known that the cause of the obstruction was due to a stone in the common duct, we could have promised something more definite from another operation, as it would have been an exceedingly easy task to remove it.

While I know of no case similar to this one—and we were governed wholly by the case before us at the time of action—it has been a most valuable lesson to me, and I want to put it on record for the good it may do others. The one great lesson it teaches, above all others, is *exploration in all doubtful cases.* An exploration might have saved the patient's life, yet I doubt this very much, in her feeble condition; but it would have given her a chance, and we certainly would have urged it if we had believed the obstruction due to a stone.

The result shows that there are remote dangers following the operation for gall-stones, which may terminate fatally as in this case. After the operation this was a most promising case, and the patient was practically well when she took the relapse. The remote dangers or complications following this operation have not been mentioned in any of the reported cases or books at my command.

The case also illustrates that obstruction of the common duct, and thus depriving the economy of bile, will cause the death of the patient in a comparatively short time.

OPERATIONS UPON THE ENLARGED PROSTATE.[1]

By WM. T. BELFIELD, M.D.,
CHICAGO.

SURGICAL interference becomes necessary for the relief of two conditions due to prostatic enlargement:

1. Acute retention where catheterism is impossible.
2. Chronic retention causing severe cystitis where self-catheterism is impracticable, or impotent to relieve.

The first condition—acute retention where catheterism is impossible—is in my experience never met, except as the result of forcible attempts to introduce metallic instruments. If the physician first called to a case of acute retention would use only rubber or elastic catheters, he would rarely fail to enter the bladder; for the obstruction is merely an œdematous swelling, not an organized stricture. Unfortunately the common practice is to resort to metal instruments and—if the first attempt fail—force; thus are made false passages, after which even the most skilful hand may fail to introduce any catheter. Under

[1] Abstract of paper read before the Mississippi Valley Medical Association, at Louisville, Ky., Oct. 9, 1890.

these circumstances the urine should be withdrawn by supra-pubic aspiration or puncture with fine trocar, a safe and simple procedure, and yet one whose value does not seem generally appreciated. After relief of tension and swelling by this means, spontaneous urination, or easy catheterism, usually follows.

The relief of the second condition—severe cystitis from chronic retention—is a more serious problem, which has, however, been solved by various operations during the past five years. Temporary drainage of the bladder by perineal or supra-pubic incision affords a relief complete, but of uncertain tenure; the factors which induced the original malady remain undisturbed; they may and, as experience shows, they often do cause a recurrence of the trouble; hence the need for radical procedures.

The simplest attempt at permanent relief is the supra-pubic fistula, a measure practised in various ways for half a century; its most satisfactory form is that recommended by McGuire, of Richmond, who makes the fistula run from the lower angle of the vesical wound to the upper end of the cutaneous incision, thus "bearing the same relation to the bladder that the spout of a coffee-pot does to the bowl." A permanent fistula is, however, a mutilation obviously to be employed only when the restoration of the natural channel seems impracticable; moreover, aside from the objections on the score of sentiment and comfort, the fistula sometimes fails to relieve the cystitis, probably because the prostatic tumors projecting into the bladder, like foreign bodies, cause mechanical obstruction. Bennett May, among others, reports three such failures in his own practice, one of which he subsequently relieved of cystitis by excision of a projecting middle lobe. It would seem only rational that if the surgeon goes so far as to make supra-pubic cystotomy and discovers prostatic outgrowths, he should certainly take advantage of the opportunity to restore the natural channel, rather than inflict a mutilation of doubtful utility in the form of a permanent fistula. In exceptional cases the restoration of the urethra may seem impracticable, and the permanent fistula, therefore, a justifiable substitute.

The removal of prostatic obstructions—the radical operation—has been sought by four avenues of approach:

1. The urethra (Mercier, Bottini).
2. Perineal urethrotomy (Harrison, Keyes).
3. Supra-pubic cystotomy (Belfield, Kummell, McGill).
4. Combined perineal and supra-pubic incisions (Schmidt, Belfield).

These represent successive stages of development; the primitive attempts of Mercier and the modification by Bottini seem to be hap-hazard procedures, based on a faulty conception of the nature of the obstruction. They may doubtless, by a happy chance, be sometimes successful.

Perineal urethrotomy secures digital contact with the prostate, and often permits intelligent operation upon the obstructing prostatic growths. Experience shows, however, that in the greater number of cases requiring operation, the prostatic urethra is too long and too rigid to permit the removal, or even the detection of the commonest obstacles, namely, the tumors of prostatic tissue which project, in the shape of median or lateral lobes, into the vesical cavity.

Supra-pubic cystotomy affords complete access to these projecting lobes, but in a few instances has failed to reach obstacles projecting into the prostatic urethra; in other words, has failed to restore a low-level urethra. Schmidt, of Cuxhaven, reports a striking example, where supra-pubic excision of a large middle lobe failed to restore voluntary urination or even easy catheterization; but, after a subsequent perineal urethrotomy and incision of a hard mass in the prostatic urethra, both were regained. I have had a case essentially similar.

In the abstract, therefore, supra-pubic cystotomy, with or without a supplementary perineal incision, as the exigencies of the particular case may require, is *the* operation for the removal of prostatic obstacles. Yet many patients are, when they reach the surgeon, too feeble to endure this procedure; in such cases the perineal operation is to be preferred. It gives temporary relief in all cases, complete cure in a fair minority, and, because so quickly performed, includes less danger of uræmia and shock, the two chief causes of mortality in these old men.

I have collected 133 operations on the enlarged prostate, performed prior to July 1, 1890. Of these, 41 were perineal (mortality 9 per cent.); 88 supra-pubic (mortality 16 per cent.); and 4 by combined incision (none fatal). An important question to be decided is, of course, whether voluntary urination can be restored in cases habitually dependent upon the catheter. For this purpose only 56 of the 133 cases are available, the reports of the remainder being incomplete.

Of these 56 persons who had been dependent on the catheter for periods varying from one to ten years, all were relieved of cystitis, and 38, or two-thirds, recovered the power of voluntary urination; in the remaining 18 the operation failed to restore this function.

Excluding the cases complicated with calculi—where it might be objected that the benefit accrued less from the prostatectomy than from removal of the calculus—there remained 41 cases of operation for the restoration of the urinary channel; of these, 32, or four-fifths, recovered the power of urination; in 9 the operation failed to restore this function. The successful cases were under observation for periods varying from six months to two and a half years after operation.

Radical operation upon the enlarged prostate is, therefore, an established procedure, worthy of general consideration; the pioneer results will naturally be improved by added experience.

INDIAN MEDICINE MEN.—THE HYPNOTIC COUNTENANCE.

By A. A. Surgeon S. S. TURNER, U. S. A.

IN a late number of *The Medical News* I printed some observations upon "Indian Medicine" as it was known amongst the Sioux Indians twenty years ago, and I purpose now some observations upon *Medicine Men*, and the "*Hypnotic Countenance*." The latter term, it is hoped, will be justified in the end.

My remarks in the previous article referred to were confined to medicine and surgery, for the reason that obstetrics is wholly a different matter with the aboriginies, and in the hands of an entirely different class of practitioners. Men are wholly excluded from the presence of the parturient patients. It fell to my lot, however, to be twice consulted in cases of this kind, in a service of something more than seven years. A description of the circumstances, and the outcome of these cases, will sufficiently illustrate the subject.

My first call was from an Indian who had served the army for some years as a scout—and was still in

the service—and had lived part of the time at a Military Post, away from his people—his duty being mainly that of mail carrier. In this way he had learned something of the practice of the army surgeons. By way of explanation he informed me that he had no faith in "Indian medicine," but was a believer in the white man's medicine. His squaw had been delivered of a papoose two days before, and the placenta had not come away. The old women could not help her, and he wished me to put her to sleep and relieve her.

I found her lying down, the cord tied with a dirty strip of calico and bound to the leg, near the knee. The old women had deserted her upon my approach, leaving her entirely alone. She was perfectly calm, and offered no objection to any of my proceedings. Not finding the placenta in the vagina, I administered ether, and found a well-marked case of so-called "hour glass contraction." Careful delivery was effected, and in a day or two the woman was about her work as usual.

My next call was from the principal chief of the largest band at the Agency, consisting of about four hundred lodges, including the following of several sub-chiefs. The afore mentioned scout was at present living with this band. One of the numerous squaws of this noted chief was suffering from retained placenta, of one or two days' duration. The shriveled old hags who constituted the midwives amongst this people did not desert the patient this time upon my approach. This was due to the patient herself. A numerous herd of them had her in charge, and were marching her about in a remote portion of the camp, the cord being tied to her leg, as in the previous case.

It was soon apparent that the chief was not master of a situation of this nature, and the usual social devices of pipes and councils were resorted to to gain time and wait for results. Various ambassadors were sent and returned, and finally the great warrior received his vassal's ultimatum: "She would adhere to the customs of her people; and, if need be, preferred death rather than that a man should come near or touch her in her present condition." On the following day the chief brought me the glad tidings that she was "all right."

Midwifery was restricted to women past the child-bearing period, and, for the most part, to the very old. Their duties were simple. They ligated the cord, received and cared for the child, rolling and packing it in such a way as to prevent movement, and leaving only the face and brow free, so that it could nurse. When the after-birth came away it was enshrouded and treated much as a corpse, except that instead of being placed upon a scaffold built either upon the branches of trees or upon posts sunk into the ground, it was hung upon a limb by a thong of dressed skin. As a physiological process, child-bearing amongst these savages differed little from "breeding" amongst common animals. Accidents were less frequent than amongst "thorough-bred" stock. There is much connected with the subject that would appear incredible to a person having no knowledge of savage life. A band of Indians on the march were not embarrassed by so simple a thing as the birth of a child. I knew a boy who was dropped into the snow. His mother rolled him in a blanket and rode twenty miles before going into camp, the temperature being below zero. I also recall the case of a woman who, as soon as her child was born, jumped into the river and amused herself bathing and swimming until the placenta came away. "Confinement" would be a misnomer applied to them, and from this standpoint may be estimated the price which woman pays for civilization and "meddlesome midwifery."

To the student of human nature, one of the most interesting studies connected with Indian medicine is the mental type of the men who alone, so far as my observation goes, aspire to fame and a numerous herd of ponies by adopting the calling. The mental constitution is usually plainly stamped upon the countenance, and denotes what I have presumed to call the "Hypnotic Countenance."

An experience of my youth made a strong impression upon me with regards to this type. Of mesmerism I knew nothing, either historically or from observation, when, out of curiosity, I attended an exhibition by a hypnotist of remarkable power. He was in the village for the first time in his life, and personally knew no one. He selected from the audience people well known to me, every one of whom possessed a dreamy, absent expression of eyes and features. He understood his business, and could tell at a glance an easy victim of his subtle power, the exhibitions of which were truly marvelous. Something inspired me to resent this power, and I defiantly placed myself at his disposal as a subject. I obeyed every instruction, with perfect confidence in my ability to resist his influence. He made no more impression upon me than if I had been a statue.

At a later period a so-called Spiritualist, to whom I was personally much attached, introduced me socially to a large and intelligent association of those of his faith, whose social gatherings I frequently attended. Here, to my surprise, I found the prevailing type of facial expression the same as that selected by the mesmerist for the demonstration of his marvelous power. I soon found it possible to judge almost infallibly who were believers and who, like myself, were interested spectators and students of human nature.

Two strongly marked examples of "the faithful" may be mentioned. The first, a sedate, dignified gentleman, of gentle, absent expression, was a trance speaker, "under the control of the spirit of Demosthenes." I think he believed this, and certainly the spirit of the great orator need not have been ashamed of his orations when in a condition of apparent trance. Whatever may have been the occult force inspiring this gentleman, his impressibility was something wonderful. I was never conscious of any hypnotic power in my own person, but by simply attracting his attention in a room, I could make him scream with terror that was strongly expressed by his features.

The second was a trance musician of great power and skill upon the piano. He had the most remarkable expression of face I ever saw—not idiotic, but dreamy almost to imbecility, and eyes that when opened had a far-away, "lachrymal aspect" that affected the observer strangely. He was "under the control of the spirit of Beethoven," so report said, and "projecting himself" into the trance condition, he would render most brilliantly not only the known compositions of the great composer, but others "composed in the spirit world," and "communicated while the performer was in the trance state."

Now, studying the medicine men of the savage Sioux, I encountered for the third time this same hypnotic countenance in its savage purity—or impurity. There was the same dreamy abstraction, not softened by culture, but bearing the impress of low, savage cunning in various degrees. There is none of the strength of the savage warrior in their

faces. As a matter of fact they do not fight, but "wrestle with the gods" while braver men rush to battle. These men are also under the control of spirits—not of Beethoven or Demosthenes, but usually of some animal, whose characteristics they imitate at times with such skill as they possess.

I recall one who was subjected to the control of the spirit of a bear. He dressed, looked, and acted the bear so far as he was able. I have seen him imitate the spiritualists' trick of working himself into a trance, when he would have his personality in that of the bear, and go through all the antics of the bear that is hunted, wounded, and finally slain. Beginning with the sinister look, and the deep, ominous growl, he would progress to frantic rage, tear the ground with his imaginary claws, and finally go into a convulsion and die, frothing blood and foam from his mouth. Presently he would come to life again—gaze vacantly and sheepishly about him, and steal away, without any one being able to "catch his eye."

All this was impressive to the savage mind, and always happened when spectators were numerous.

It may not flatter our vanity to suppose that "historic medicine" had its birth, if not its baptism, in the hands of men of this same type, but there is abundant reason for such a suspicion. And even in the present day this element supplies the "magnetic healers," the "faith curers," and quacks in general, while not a few of the higher branches of the mental tree drop into the mystic pool of Hahnemannism. But in the representative assemblies of the regular profession the hypnotic countenance is overshadowed by as strong and manly a set of faces as will be found in any other cultured assembly in the world. And yet, the ghost of this intellectual mysticism hangs about our camp, as is shown by the number in each rising decade who revive the hypnotic craze; who go wild over "methods" that are at best but dramatic and hurtful; and who from new and little understood discoveries, as the bacillus of tubercle, jump at conclusions which contradict the accumulated results of two thousand years of intelligent experience and observation.

Men now talk of hypnotism not only as if it possessed great possibilities for good, but as if it were a power at the command of all, and applicable to all individuals; while, as a matter of fact, relatively few are susceptible to the influence in any marked degree, and fewer still are capable of exercising it in a marked degree. According to my observation it is a power that, when possessed at all, can only be exercised by the stronger upon the weaker; and it is believed, by some at least, that the interposition of the stronger will of a third party will neutralize the power of a hypnotist in a given case. I recall a clergyman of wide learning and more than ordinary force of character, who assured me that he had repeatedly controlled this mysterious force by simply "making the sign of the cross." That he was truthful and sincere I could not for a moment doubt, but I could not accept his conclusion. What he attributed to the mystic power of a religious symbol, I attributed to his superior will-power. He believed that all the phenomena of "animal magnetism," "mesmerism," "spiritualism," "hypnotism," or by whatever name called, had their origin in evil. That it is purely a natural power, but little understood, I am equally confident. But that it may be a power of great evil in evil hands, there is no reason to doubt; while we may reasonably doubt that it has any known power for good. There is great usefulness, of course, in the mental force which enables one to control an obstreperous patient, as in cases related by Emmet and others; but it is doubtful whether such exhibitions belong to the class of hypnotic phenomena. They are evidences, rather, of the power which makes men leaders of men.

THE WEST INDIES AS A SANITARIUM.

By WILLIAM F. HUTCHINSON, M.D.

CHAPTER V.

BEFORE leaving St. Kitts, a gentleman sitting by my side remarked (we were then on our return-trip from Trinidad): "If somebody who had taken the trouble to write articles about these islands had only told us when we were here before that the very best green turtle dinner that the world can afford is furnished by the proprietor of the American Hotel at Antigua, upon receipt of a telegram to that effect from here, my opinion is that everybody would be very glad to take it in." So upon this suggestion I put it down. It is one night's trip across an arm of the sea to Antigua, and the ship dropped anchor, early in the morning, at the nearest point to the picturesque town of St. Johns that lay spreading out at the foot of a mountain three or four miles away.

From our anchorage, Mr. Ellery, the courteous harbor master, took us in in his steam launch.

There are as attractions in the city of St. Johns, the prettiest work in black and red seeds that I ever saw, specimens of petrified tropical woods from the valley a little way inland, called the "Valley of Petrifactions," and a public library containing several thousand volumes, large school maps of the island, with a collection of natural curiosities which would be of some use if they were labeled.

Also there is a beautiful view from the upper windows of a fine cathedral.

The drives about the island are not especially interesting, for it is devoid of striking contrasts of scenery, but they are of quiet beauty, and the air is heavy with the scent that makes even tolerable roads enjoyable. For the rest of the description of this island, my friend Dr. Gardiner has consented to provide our readers with one, which is as much better than mine as might be expected from an old resident. Listen to him.

"Antigua is situated in the Caribbean Sea, between 17° 2′ and 17° 3′ north latitude, and between 61° 44′ and 61° 58′ west longitude; of a rough circular figure, twenty miles long, fifty-four in circumference, and much indented by creeks and bays.

"Although properly classed with the Calcareous Islands, not half of its strata come under that description, while the remainder consists of trap rocks and curious marine and fresh water deposits, furnishing the amateur geologist with many interesting facts and problems.

"The island is flat, with the exception of the south-western division which is hilly. Some of these mountains rise with conical summits to the height of one thousand feet; others, of the same elevation, are more rounded and less precipitous, affording a good soil for sugar-cane. They are intersected by beautifully romantic valleys, and the abrupt sides of the mountains are clothed with the verdant foliage of a great variety of herbs and twining shrubs.

"St. Johns, the capital, is on the northwest coast of the island, and presents on the approach to the harbor a very picturesque appearance, from the beauty of its situation and generally neat aspect. It is a well laid out city, the principal streets are wide, crossed by others at right angles, and the town ex-

tends from east to west, having a gentle declivity towards the harbor, the highest point being about forty feet above the level of the sea. The water supply is ample, and is conducted by iron pipes into every street of the city.

"The Board of Health is vigilant, and the hygienic condition of the town is very good; in fact, the members of the Board pride themselves in saying that no other town in the West Indies can compare with St. Johns from a sanitary point of view.

"Climate:—The weight and temperature of the atmosphere vary but little throughout the year, and especially is this so during the months of January, February and March, when the fanning trade wind holds its steady course, infusing health and vigor into every living creature. The mean temperature of the year is 78° F.; the maximum, 89° F. During January this year the highest temperature registered was 80° F., the lowest 74° F., average being 76° F. During February the highest was 80° F., lowest 74° F., average 78° F. During March the highest was 88° F., lowest 74° F., average 80° F. The above figures were taken by a Fahrenheit thermometer at 9 A.M. and 4 P.M. each day, but during the cloudless moonlight nights at this period of the year the mercury occasionally falls to 66° F.

"The rainfall for January this year was 5′ 21″; for February, 1′ 00″; for March, 2′ 51″. In comparing the rainfall for these months during the last ten years, I find that we have had more than the average amount this year.

"Accommodation:—At present we have one comfortable hotel, capable of putting up from twelve to eighteen visitors, at a cost of thirty-five dollars a month; but there are private boarding-houses where board and lodging can be had at a cheaper rate. I may mention that the members of the Legislative Council are at present considering the advisability of granting a subsidy of seven hundred pounds per annum, with the view of establishing a first class hotel on American principles, so as to perfect as far as possible the island as a health resort.

"As regards luxuries for the table we are very well off here. For example, ice at one penny per pound; oysters at one penny per dozen; turtle eggs, green turtle, for a few shillings; venison seven pence per pound; land crabs, guinea fowls, a large and varied supply of fish. Tropical fruits abound, Antigua being famed far and wide for its pine-apples, which can be purchased for a few cents each.

"By way of amusements we have a well-stocked library, an abundance of tennis courts, cricket, billiards, shooting, Cinderella dances, concerts, etc. The sea bathing is charming, the water of a beautiful blue color, never too cold, just sufficient to enliven and invigorate, and can be enjoyed by all.

"The inhabitants are hospitable, and from being the seat of government for the Leeward Islands, the society can compare favorably with the surrounding islands. We have two clubs, where strangers may be introduced and pleasant evenings spent.

"Roads are good, and ponies can be had for the saddle or buggy at a cheap rate.

"The Registrar-General has kindly supplied me with the following statistics: The number of deaths of persons over twelve years of age, in the city and parish of St. Johns, representing a population of seventeen thousand, for the months of January, February, and March, this year, was eighty-five. Of that number old age and debility is credited with thirty; heart disease, fourteen; phthisis, twelve; dysentery, five; bronchitis, four; affections of brain (including apoplexy, etc.), four; diarrhœa, three; pneumonia, two; dropsy, four; syphilis, two; uræmia, two; leprosy, one; cancer, one; tetanus, one. Of this number probably not more than two or three were white. Heart disease is a common cause of death among the negro population, originating in the practice of carrying heavy burdens on their heads for long distances, without rest or refreshment.

"The number of deaths from phthisis requires to be explained; for, certainly, twelve deaths look ominous in a place posing as a health resort; but when we consider the patients afflicted, the nature of the malady, and the circumstances under which the disease runs its course, the number of deaths is not so alarming as it would appear at the first glance. Firstly, as to the patients. Negroes have not the stamina of the white man, and cannot withstand the attacks of any disease (more especially so is this true in respiratory and cardiac affections) for any length of time, and succumb very rapidly. Secondly, as to the nature of the malady. Phthisis, contracted here, tends rapidly to a fatal issue. Thirdly, as to the circumstances. The negro is ignorant of the most elementary ideas of nursing, and nursing is nowhere of more importance than in phthisis.

"When we come to deal with phthisis in the white population, we find the disease has a different history, especially where the lung mischief has been contracted in a cold country. Then, istead of a rapid progress, the lesion appears to be checked and lies dormant for a long time. Patients with alarming hemorrhage and large cavities, who possibly, if they had remained in a variable climate, would probably not survive another winter, are by a continued residence here improved in health and spirits, and enabled to earn their own living.

"Patients in whose lungs the tubercular bacillus has found a suitable nidus, and taken no uncertain hold of, will be benefited by a residence here, but not cured, that is, using the term as meaning a complete and thorough elimination of the bacillus from the system. I am afraid phthisis here as elsewhere makes truces, but never peace.

"Incipient phthisis and chronic bronchitis benefit by a short residence here in a most remarkable degree; the cough becomes less troublesome, the secretion lessens, and patients gain in health and weight in a in a very short space of time.

"Renal lesions are uncommon in our population, and cases contracted in a cold country do well here. Syphilis is common, but of a very mild type, many of the natives seek treatment, and a fatal result is rare, residence in a warm climate affecting the prognosis considerably for the better.

"Acute rheumatic fever and vesical calculi are practically unknown.

"Business men, nervous and melancholic from over-work and worry, will find a trip to Antigua healthful, pleasant and agreeable, returning home in good spirits, refreshed and invigorated.

"From the above statistics it will be seen that there are no deaths from fevers. Visitors need not be afraid of contracting any malarial taint, which, when it is prevalent in the autumn, is of the mildest type of any in the West Indies. An epidemic of yellow fever has not been known here for over twenty years. PETER GARDINER, C.M., M.D."

In addition to what my friend Dr. Gardiner has said of the hotel accommodations at Antigua, I must put in a word for the excellent green turtle dinners that are served at the American Hotel at short notice, and remind my readers of what I said in a previous

paragraph about cabling over from St. Kitts at the landlord's expense, to have one of them ready when the ship gets in.

There are the usual stories about Captain Kidd going about Antigua, and one of our passenger picked up a fine specimen of a pine-tree shilling for a few pence, which he afterwards sold for thirty-five dollars, which, of course, came from the pirate's hoard.

About the lovely bay, which is full of pretty islets, there is good fishing and sailing for those who like the water, and, take it altogether, it seems to me that a tourist might do far worse than to settle down for a couple of winter months in St. Johns.

Of the island of Dominica there is more to be said from the tourist's point of view than from that of a sanitarium. Some four hundred years ago when Columbus sighted the lofty peaks of Roseau, it chanced to be Sunday, and the captain, with his usual piety, named it Dominica, Sunday Land.

Its capital town is anything but interesting from an artistic or comfortable point of view. There is nothing in the shape of an hotel, nor even a boarding-house, that I could find, but the inhabitants, with generous hospitality, are always ready to find comfortable resting-places for those who come to stay among them.

But if the town is not attractive, the island itself is very much the reverse, for of all the scenery that the West Indies boasts, whether of mountain gorge, deep, dim, verdure-clad valley, or of precipitous orchid-clad mountain side, there is no better example than may be found in beautiful Dominica. One cannot obtain even a slight idea of its beauty without going at least as far up the hills as the famous fall of the boiling springs, and as this involves an entire day, there are few of the tourists by any of the present lines who have an opportunity to study it. Then, too, on the other side of the island from the town of Roseau, there is a tribe of ancient Caribs, or of their descendants, who retain in that inaccessible spot the customs, costumes and manners of the native lords of the soil. But there are twenty-five miles of virgin forest, glades and mountain gorges to traverse to reach them, and one must camp out one night on the way, as there are no places to stop, and as this requires a fitout of servants, animals and tents, there are not many who venture upon the expedition.

But I cannot leave Dominica without speaking of the well-known boiling springs to which we did go, and which I carefully examined.

Leaving town early in the morning, accompanied by a guide, I rode out of the city and set my face toward the distant mountain. Beyond a shallow stream that wound across the path, where darkey women were washing clothes between two rocks, the road plunges into a vast plantation of lime trees, whose golden fruit hung thick overhead among the dark, waxy leaves, or rolled in profusion among the horses' feet, till we came to the factory where the juices are squeezed out, boiled down and shipped to England to be bottled. A little later on, we began the steep ascent upon a road that wound steadily upward beside a mountain stream, in the cool shade of overhanging cliffs, and such glorious luxuriance of tropical foliage as is rarely found, even in these islands. There were clusters of tree ferns, sixty or one hundred feet high, with trunks as thick as one's body, and leaves ten feet long, each one as delicately cut as the little fronds that we find in dark valleys of our own mountains. What the names were of other trees around us, each one of which was wound with parasitic vines, loaded with air plants of every kind, we had no means of ascertaining, for none of us were botanists.

We halted by midday for a little lunch at a point where the barometer measured twenty-two hundred feet elevation. At this place was a sugar estate called "Wotten Waven," that belonged to the American consul, Mr. Steadman. After luncheon we kept on our way until in a ravine we heard the jerky puffs of steam like a high pressure engine, and began to smell the sulphur of the boiling springs. In the bed of the stream made by the spring water, there was a circular depression some six feet across, in which thick blue mud was seething and boiling in the fiercest way. Little cones from the mud burst with mimic explosion, and gave place to open craters which in turn soon became cones. Beneath the ledge on which I sat to sketch, there was rumbling and trembling as of a steam boiler close below with the safety valve tied down. It soon grew so hot that I was glad to get up, and a thermometer bulb, pressed upon the spot I had vacated, marked one hundred and sixty degrees.

A little farther on was the main spring about fifteen feet across, over which, even in that hot air, were clouds of steam. I went to the edge of the water with considerable caution, and found its temperature two hundred and eight degrees. In a moment there came an eruption, and jets of boiling water from every part of the surface were thrown up at least twenty feet in the air; then an interval of quiet of six minutes, and another eruption, and the guide said that this was the usual condition of things. Although the vapor of the air was loaded with the scent of sulphurated hydrogen, I found no evidence of free sulphur to any extent. Stones and limbs of trees in the water course showed no deposit, and a silver coin, held a few minutes in the stream, was not discolored. Probably the metal was vaporized by the intense heat of the spring. Farther on in the depths of these virgin forests, there is a great boiling lake which has been visited by very few white men. My friend Ober, author of "Camps in the Caribbees," is the only one, as far as I know, who has made any study of it, and I commend a trip to the boiling lake of Dominica as worthy the attention of tourists.

Dominica, West Indies, March, 1890.

ADMINISTRATION OF MORPHINE BY THE NOSTRILS.[1]

By CARL H. VON KLEIN, A.M., M.D.,
DAYTON, OHIO.

IN the administration of morphine by the mouth there is generally, besides an inprecipitate taste, a great deal of hacking and spitting, in many to such an extent that it produces an irritation of the throat, especially of the soft palate. If used repeatedly it excites the same irritation of the lips and tongue as in the use of opium, and has been known to blister the mouth. In persons not accustomed to the taste of morphine it produces nausea and vomiting.

Dr. Billroth[2] reports in the case of a lady who took small doses, 0.007 gramme (gr. $\frac{1}{9}$), and even 0.003 gramme (gr. $\frac{1}{22}$), he saw such anxiety, nausea, and vomiting, that, although suffering intense pain, she refused to take the remedy again. Cases of the same nature have been reported by Laborde.

Dr. Wernick[3] has called attention to the occurrence of a paræsthesia of taste after the use of morphine.

[1] Delivered before the American Rhinological Association, October 6, 7 and 8, 1890, Louisville, Ky.
[2] Wiener med. Wochenschr., 1868, p. 763.
[3] Archiv f. Psychiatrie, Vol. ii, p. 174.

As a rule where persons are found to dislike the taste of morphine, or where it is desired to have a rapid physiological action, the hypodermic is resorted to. This, too, finds opposition, on account of puncturing the skin and the danger of producing abscess.

The new method of administering morphine through the mucous membrane of the nose, which I will now describe, has been thoroughly tested by me in over one hundred cases, where the immediate physiological action of morphine was necessary. I have found it to be the most reliable, tasteless, and prompt action than given by the mouth or hypodermic. It requires much smaller doses than taken by the mouth, and no larger than given hypodermically.

The manner of administering morphine through the olefactory canal is simply by snuffing it up the nasal chambers in the same manner and in the same way as snuff tobacco is used. You divide the dose intended in two equal parts; each part is placed upon the end of the thumb and snuffed up into the nostrils. The membranes being very soft and delicate, it instantly appears to absorb. I have tried it myself on several occasions, and it seemed almost instantaneous absorbtion. No more than fifteen seconds after the introduction I have blown my nose and nothing could be found in the secretion.

However, in poor qualities of morphine the drug will not absorb so readily. In cases where the nasal chambers are incrustated and covered by dry secretion, the cavities should be cleansed before administering. Care should be taken not to snuff it up too strong to engulf in the throat. If the drug is of a poor quality it will produce sneezing, but the narcotic effect will be the same.

The administration I have now described, you will find, besides the tasteless and rapid action, to retain the narcotic effect for a longer period than taken by either mouth or hypodermic.

COUGH, OF NASAL ORIGIN.[1]

By A. B. THRASHER, M.D.,
CINCINNATI.

COUGH is a reflex phenomenon due to the irritation of a nerve fiber in the air-tubes, larynx, pharynx, nose, ear, stomach, etc.

A normal cough is for the purpose of freeing the air-tract from some foreign body. Irritation of the upper part of the trachea, and of the ventricles of Morgagni, most frequently produces cough. An irritation in many other locations may be referred by the sensory centers to this region, and thus give rise to cough. Inflammation of the cavernous bodies of the nose or of the adjacent septum has been known to give rise to a distressing cough, and has been mistaken for an evidence of tubercular disease. This is more apt to occur in a person of neurotic temperament. The cough due to nasal disease may sometimes be recognized by its metallic ring and absence of expectoration. It can, as a rule, be provoked at will, by touching the irritable spot in the nose with a silver probe. Dr. Thrasher recited three cases illustrative of nasal cough from his private practice.

CASE I.—There were no subjective symptoms of nasal disease. The cough had been present for three months, and was not benefited by the usual cough mixtures. The lower turbinate was found to be hypertrophic, and touching it with a probe provoked violent coughing. The cautery was applied, and in three days the patient ceased to cough.

[1] Abstract of paper read before the Mississippi Valley Medical Society, Louisville, October, 1890.

CASE II.—A young lady had been coughing violently for three months. She referred the irritation to the throat, which had been penciled and sprayed, for some time with no relief. Touching the posterior extremities of either lower turbinate produced violent cough. Treatment as Case I, with good result in two months.

CASE III.—Cough had been present six months and was not benefited by constitutional or local treatment. The seat of the trouble was found to be in the left middle and right lower turbinate. Treatment similar to other cases was followed by cessation of cough within a month.

"A FEW 'POINTERS' FOR THE GENERAL PRACTITIONER."

By HERBERT A. STARKEY, M.D.,
HEGEWISCH, ILL.

A VERY valuable suggestion I received in the Windy City was in regard to the lightest kind of a fracture dressing. Plaster bandages are heavy and disagreeable to apply; the same can be said of starch and the others. Get the stuff called "wiggin," used by the fair sex to stiffen certain portions of their clothing. Make it into the necessary size bandages, and when needed soak in hot water and apply; in a short time you have a light, hard dressing, which can be covered with shellac, cut with a sharp knife, and laced as a corset or shoe.

We all have to throw a light into some cavity of the body at times, and the stronger the light the better, but the beautifully nickel-plated, double lens concentrators cost more than we, perhaps, can just now afford. So, until our cash account grows, we will take a common police dark lantern, cut the rim from top and bottom, solder a piece of reflector on the posterior wall and set it on any kind of a lamp, and if the chimney won't fit inside put it on top, and you have a good concentrator of rays, and one which you can throw in your bag to carry and use anywhere.

After you have turned the light from this down someone's throat they will remember that the baby has an earache, and as you will need something better than the paper cone to blow the necessary boric acid at the diseased part, we will manufacture an insufflator; take a hard rubber thermometer case and an atomizer bulb, cut the thermometer case in half, drill a hole in the small end, and at the other wind a piece of stiff paper tightly, letting the paper project about an inch beyond the tube; now take the other piece, open up the end and attach the atomizer bulb, cut the other end bias, making a lip with which to scoop up the powder; fit in the paper, squeeze the bulb, and you have quite a respectable powder blower.

One who is liable to get surgical cases should not be without a half dozen pairs of hæmostatic forceps ready to hand; but if we are not the possessors of these valuable inventions of Tait, we go to a furnishing store and get a card of the ordinary clips one finds on the anterior extremity of our suspenders and on sleeve holders; for ten cents you have a dozen pair of hæmostatic forceps that have held a femoral artery in several cases. They are not built on the antiseptic plan, but boil and soak them in carbolic acid, and the germs will be too ill to cause any trouble.

None of these ideas are original, but I have tried them all and found them good; for the last suggestion I am indebted to Dr. Hurd, of Jefferson Hospital, Philadelphia, who I have seen use the clips on several occasions in preference to the regular forceps.

Society Notes.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, October 8, 1890.

The Vice-President, JOHN B. ROBERTS, M.D., in the Chair.

A REPORT OF INTERESTING AND IMPORTANT ABDOMINAL SECTIONS.

DR. MORDECAI PRICE submitted a paper with the above title.

Mrs. S., forty years old, suffering from chronic inflammatory pelvic trouble, probably the result of a badly treated abortion.

The law laid down by Mr. Tait, to finish an operation when once begun, at any cost, is unquestionably true so far as the patient is concerned; but the point to which I wish to call your attention, in reporting this case, is, should not the feelings and the anxiety of the operator in this desperate work receive some consideration?

The patient came to my office for an examination and relief. I found both sides diseased and greatly adherent, the uterus immovably fixed, much tenderness; unable to attend to her household duties, general condition miserable. An operation advised and consented to; weight of patient, probably two hundred pounds.

Operation.—Quite a good deal of hemorrhage in the abdominal wound, two and a half inches in length; everything adherent in the pelvis—bowels, bladder, uterus, and omentum, and I knew that to remove this diseased condition of the tubes and ovaries would require a long and tedious enucleation, involving great shock and loss of blood, and with the indorsement of my brother, who made a careful examination, I decided to remove the diseased parts. The enucleation required almost an hour for its completion, and the hemorrhage was terrible; the diseased parts tied away, all the large vessels secured, still the bleeding was very troublesome. Sponge-packing and warm irrigations were used to stop the blood, which seemed at the time to control it. Patient at this time was pulseless at the wrist, sighing respiration, and greatly shocked. Drainage tube placed, abdominal wound closed, and patient put to bed; but a great deal nearer dead than I would like to see another. It was some twelve hours before reaction was complete; during this time two ounces of pure arterial blood was removed through the drainage-tube per hour. At no time was the patient in a condition that I could reopen and use any means to stop the blood. As reaction slowly took place the hemorrhage decreased, and at the end of twenty-four hours the quantity was only about one-half ounce per hour, and slowly decreased until the end of the fourth day, when the drainage tube was removed. To know how I felt during that first twenty-four hours, I advise you not to experience it to find out. This patient went steadily on, and made a good recovery.

To have stopped anywhere during the enucleation and closed up the abdominal wound, would certainly have been attended by a fatal result.

Mr. S., Dr. Dundor's patient, sixty-eight years old, suffering from obstruction of the bowel from distention, the result of paralysis. There were inflammatory bands at the sigmoid, but not sufficient, I think, to be the cause of the trouble. On June 4th I was asked by Dr. Dundor to see the patient in consultation. Dr. Dundor had only just been called to attend the case; he had had two previous attacks almost identical with this one, though not so long nor so serious in character.

We found the patient, a man over six feet in height, lying on the broad of his back, with his abdomen distended almost to bursting, suffering great pain from the distention, no vomiting. He was taking at this time small doses of calomel; forcible injections had been used, but the bowel would retain but little fluid, showing the obstruction at the sigmoid.

This was the eighth day without a movement of the bowels. The patient's condition did not indicate an inflammatory condition. We considered it safer, owing to his present condition—no vomiting, pulse but little accelerated, temperature but little above normal—to wait rather than proceed with abdominal section. Epsom salts were ordered in one ounce doses, to be given every four hours until the bowels were moved or symptoms of more serious character made their appearance. Four ounces of salts were given before I next saw the patient.

Dr. Dundor was to see the patient early next morning and send me word as to his condition. He was detained with a serious case of labor, so we did not see our patient until the evening. I then asked my brother, Dr. Joseph Price, to see the case with us. He heartily abused me on the way to the patient's house for not operating when I first saw the patient. After a thorough examination, he agreed with us that it was better to wait even then for daylight, rather than operate in the dark. We left him, with the understanding that if there were no favorable change we were to be called at 5 o'clock in the morning, when I would do an abdominal section.

At 5 o'clock sharp I was notified by the messenger that the patient was rapidly growing worse, and wanted something done for his relief. At 6 o'clock, with the assistance of Dr. J. Price and Dr. Dundor, I opened the abdomen midway between the pubis and umbilicus, making an opening three inches in length. So great was the distention that the mere touch of the knife made a great gaping wound. On examination, the large intestine was found distended to the size of my thigh, the small intestine empty. After a short examination, finding we could make nothing out of the condition, the incision was enlarged, and the bowel brought out and an opening three-quarters of an inch made in it. Gas and feces were driven with great force through the window into the street. We removed a large, old-fashioned tin basinful of liquid feces, all the gas and all the contents of the bowel that we could remove, probably two gallons. The bowel was thoroughly washed and examined, the adhesions at the sigmoid were torn away, wound in bowel closed with fifteen Lembert sutures, and again thoroughly washed. The estimated length of colon when returned was ten feet. Patient put to bed in moderately good condition, suffering but little that day and night. On the following morning, at 9.30, I found him taking a bath in a bucketful of liquid feces, from his head to his heels; he was quite comfortable in every way, barring his filthy condition. I was delighted to see the salts having such a happy effect. I scarce need tell you that I cleaned him; both Dr. Dundor and myself had to continue to do so every day for a week. The salts taken previous to the operation unquestionably saved our patient. He went on without intermission to a rapid recovery.

I wish to call attention to the fact of the immediate closure of the intestinal wound. It must have been immediate, or there would have been leakage.

PAROVARIAN CYST STRANGULATED AFTER DELIVERY.

Mrs. W., confined July 18, patient of Dr. Hinkle. This tumor was known to exist prior to labor. No complications made their appearance until the third day after her delivery, when the patient, turning on her left side, felt the tumor move completely across the abdomen, and experienced severe pain. This pain did not decrease; her symptoms became more serious daily, and on the third day her condition became so alarming that her attending physician decided there was a strangulation of the tumor from twisting of the pedicle.

A consultation was decided upon, and Dr. Hinkle asked me to see the case with him. After examining the patient, I concurred in his diagnosis. A section was advised at once, and was promptly accepted by the patient and family.

The operation was performed at 4.30 A. M. The temperature was 99°, pulse 150. The temperature went up for forty-eight hours from normal to 103½°. The pulse continued also to increase, and about six hours before the section was done the temperature dropped to 99°, pulse 150—every indication of collapse. The operation was proceeded with at once; patient etherized, placed on the table, parts thoroughly cleansed, inch and a half incision. Black and discolored walls of tumor came at once to view; a knife had to be used before a trocar could be pushed through the walls of the tumor. About twelve or fourteen pounds of fluid were removed from the tumor, four complete turns of the tumor on its pedicle, the twisted portion including the ovary and tube, all of which were discolored and in a semi gangrenous condition down to and including a part of the cornua of the uterus. The ligatures included part of the cornua of the uterus. The tumor was cut away, peritoneum generally inflamed, thorough irrigation, glass drainage for twenty-four hours. This patient made a beautiful recovery in twenty-one days—was practically well in a week. Nursed her baby all the time but two days.

Mrs. W., aged thirty-six, married fourteen years; suffering with double pyosalpinx; probably a pint of pus in both tubes and peritoneum; a general peritonitis existing. One ovary was completely destroyed by an abscess, the other could not be found. General adhesions to bladder, pelvis, floor, bowels, and all surrounding structures. The enucleation was very difficult; both tubes completely removed with irrigation and glass drainage. The patient's history is an interesting one, having in the past six years suffered from an old-fashioned pelvic cellulitis or peritonitis with five different attacks, in four of which I attended her; and I have no doubt as to the cause of these attacks. She was suffering from chronic tubal trouble; cold or exposure increased the irritation of the tube. There was leakage, consequently a new attack of peritonitis. As long as the patient was in a fair condition the fluid was absorbed and she improved, and after weeks of suffering, and on one occasion months, she returned to a moderate state of health; but at no time was the uterus free, nor the ovaries and tubes movable. There was always great tenderness on pressure.

At the last attack the patient was in a septic condition, with general peritonitis and every indication of approaching death. She made a slow recovery, her septic condition greatly retarding it.

Discussion.—Dr. A. J. Downes: I had a case in the last four days which is somewhat similar to the case of obstruction reported by Dr. Price. In March last I operated on a woman weighing two hundred pounds, with thick abdominal walls. I closed the wound without drainage. She suffered with pain for ten days. All summer she suffered with constipation and intense pain after movement of the bowels, which was only secured by large doses of salines and magnesia. She wanted me to operate, and on Saturday I did so, and found the cæcum and the small intestine bound together, and the appendix between them, and all adherent to the right cornua of the uterus. In the four days prior to the operation she took eight bottles of magnesia and two ounces of salts. There was not complete obstruction, but the bands of adhesion were very firm. I think that this case should have been drained on account of the thick abdominal walls, which must have bled very freely. In the last operation I drained, and the patient had a natural movement of the bowels two days after the operation. She is doing very well. The appendix was four inches long, and inflamed, with many adhesions. I removed it; which, I think, was good surgery.

Dr. William S. Stewart: There is one point which Dr. Price emphasized that I think we should all consider, and that is, in every intricate case in which we have begun an operation, that we should not give it up half done. I had such an experience not long ago. A number of good operators who were present advised me to hurry up or the patient would die on the table. It was a case of degenerated ovary and abscess, with adhesions not only to the walls of the abdomen, but deep in the pelvis to the psoas muscle. There was no place where I could entirely remove the sac. The wall was so degenerated that it was torn in my efforts to remove it, and large quantities of pus escaped into the abdomen. Even before the operation was begun the patient seemed to be in a dying condition. I decided, however, to make an exploratory incision, and, finding such a serious condition of affairs, determined to continue the operation. I dissected away the wall of the abscess as cleanly and carefully as possible, and washed out the abdomen. Hypodermic injections of strychnine, digitalis, and stimulants were given, and when the patient was removed to the room her temperature was 96°. She, however, made a good recovery, and is well to-day.

In regard to drainage: In one case of extra-uterine pregnancy I was compelled to use drainage five days before I was satisfied that it was safe to remove the tube. The patient did well, and recovered.

In regard to operations during gestation, I wish to caution the society against hastily deciding on such operations. I remember one case when I was asked to be present at an operation where it was stated that the patient had a fibroid tumor. The woman was a former patient of mine, and before the operation I made an examination and advised her to postpone any operation for the present. At the end of a month she again called, and I suggested still further postponement. The operation was again indefinitely postponed, as the woman felt life in the tumor. It was a rare case of retroflexion with conception. I did not replace the uterus until labor set in, and delivered her successfully; and it is, I believe, the only case on record in which mother and child, under such conditions, were saved.

Dr. J. M. Baldy: My thoughts have wandered over quite a large field as Dr. Price has narrated his cases, and many interesting ones have occurred to me. This point of prolonged drainage after extra-uterine pregnancy: I have noticed, and have come to the conclusion, that drainage must be prolonged

in such cases, at least where the placenta has attached itself to the pelvic wall—as has been the rule in most of my cases. Looking at the condition of affairs in the pelvis, we can see why it is that prolonged drainage would be needed. The branches of placental tissue penetrate the pelvic wall, and much of this bleeding tissue must be left. We know how vascular placental tissue is, even in its earliest formation, and I think that we will find that all cases will require comparatively prolonged drainage.

The subject of unfinished operations is one of extreme importance to everybody in abdominal and pelvic surgery. I have often been tempted to give up an operation in the midst of it, leaving it half done. Unless the principle of always finishing what was begun had been thoroughly rooted in my mind, I should have fallen into that great error. After operation is begun, and hemorrhage started, it is folly to take the great risks of an unfinished operation. The chances are better by going on and enucleating the disease and getting a ligature around the base of the mass. It may sound rather reckless to say that one will not stop and leave an operation unfinished, but the time to hesitate is before beginning. The time to make up the mind in regard to the feasibility of finishing the operation is before one begins the enucleation. After the abdominal cavity is opened, exploration should be made and a fixed decision arrived at. If in any doubt as to the possibility of finishing the operation, it should not be begun. If begun, it should be finished. I can call to mind just now four unfinished operations, and all the patients succumbed. I should take large risks of the patient dying on the table rather than the still more dangerous risk of putting the patient back to bed with hemorrhage coming from I know not where.

The case of obstruction of the bowel was very interesting. These cases of obstruction are often difficult to deal with from a diagnostic point of view. It is often difficult to determine what we shall do, or if we shall do anything of a surgical nature. I recall the case of a colored girl twelve or fourteen years of age, which was under my care some years ago. She had obstruction of the bowels. One day she was better, and the next worse. She was up and down in the way with which you are all familiar, and I was uncertain whether to operate or not. By the time I had made up my mind to operate, the patient was dead. It was just as well that I did not operate in this case, for there was an immense amount of tubercular disease about the cæcum, and at the post-mortem the bowel ruptured at a point where it would have been impossible to have reached it or dealt with it in any way.

I have lost a case where obstruction of the bowel followed abdominal section. For four and a half days I tried to get the bowels open. The patient did not vomit a single time; she had a flat belly for two days. She took salts and calomel in large quantities, and retained them. The middle of the third day the abdomen began to distend. There was no discharge from the bowel. She was given repeated enematas ubsequently containing turpentine. A slight amount, ot fæcal matter was removed from the lower bowel. During this time the patient was apparently in good condition, with a pulse of from 80 to 90, and a temperature below 100°. There was, of course, colicky pain. At six o'clock on one evening the pulse rose to 100, and the temperature to 100°. By midnight the pulse was so rapid that it could not be counted, and the temperature was 103.5°, dropping in an hour to 97°, and the patient died before I could reach her when summoned. At the post-mortem, I found the descending colon completely collapsed from the splenic flexure to the sigmoid. The rest of the intestine, without exception, was distended with liquid contents and gas. I could find no cause for the obstruction. There was no kink, no volvulus or pressure.

Cysts complicating pregnancy should be dealt with as Dr. Price has suggested. I never had a large cyst in which the pedicle became twisted and the cyst became gangrenous at this time, but I have seen six or seven cysts in which inflammation has been set up at the time of the labor, and the woman had afterward suffered from severe puerperal trouble, and the cyst had become generally adherent, and for months and years had caused discomfort, and had subsequently to be removed; at the time of the operation considerable difficulty was experienced on account of the adhesions.

I think that most cases of pyosalpinx go through the course prescribed by Dr. Price, viz., repeated attacks of peritonitis. We cure the peritonitis, and the patient is relieved of her symptoms for a time, and we suppose she is cured. We have many such cases on record.

Dr. John C. DaCosta: I believe in the general rule of finishing an operation after you have begun it, but do not think that we should lay that down as a *cast iron rule*. As I speak, three cases occur to me which I feel sure would have died if I had persisted in continuing the operation. In one case I opened the abdomen and there was one mass of adhesions. It was almost impossible to distinguish anything. I tried to break up the adhesions, but found the mass could not be removed without probably killing the patient. The hemorrhage was severe and controlled with difficulty. It was finally stopped, the abdomen closed, and the patient put to bed. She made a rapid recovery. Although I did not get away the tubes and ovaries she is now comfortable and has menstruated without trouble. She suffers with neuralgic pains in the head, but the abdomen is free. If there is such a thing as "pus tubes" this undoubtedly was such a case, and from the history it was probable that the husband had something to do with it.

In the second case I could not make a clear diagnosis of the condition of the parts. I felt sure that the patient had sarcoma, and the question was, whether or not a pedicle could be found and the sarcoma removed. A sarcoma was found filling the entire pelvis without the possibility of making a pedicle anywhere. Had the operation been finished I should have had a bleeding surface as large as my hand, without the probability of stopping the hemorrhage, and we all know how sarcomas can bleed. I removed some thirty-five or forty pounds of fluid, and made her comfortable, and in ten days she was ready to go home. That woman will die in the course of six or eight months, but I think that she would have died on the table if I had persisted in the operation, and feel that I was right in not finishing it.

In a third case a woman came over two hundred miles to see me. I felt sure that she had a sarcoma. She had an indistinct scar on the abdomen, indicating that a former section had been made. I was, however, assured by the husband, who, I am sorry to say, is a physician, that such was not the case, but that the scars were the result of tappings. I did not believe him, but at his urgent request made an exploratory incision, and found a condition of affairs similar to that noted in the second case. I removed a large quantity of bloody fluid, and the woman was able to go home in a week. Two or three

days later the husband told me that a distinguished surgeon had made an exploratory incision some time previously, and had refused to go further. Here we have the authority of one distinguished man, who says, by his work, that it is not always wise to finish an operation.

In those cases where there is pus, or much blood, or even much serum, it is well to put in the draining-tube. There is no rule as to how long it should remain. You may take it out in twelve hours, or you may have to keep it in a week, or you may not need to use it at all; every patient is a law to herself.

Dr. William E. Ashton: I agree with the gentlemen who have preceded me, in regard to unfinished operations. I believe thoroughly in exploratory incisions. I think that we may have an exploratory incision without an operation. I do not think that it is necessary to go on with an operation because we have made an exploratory incision, but if we once so disturb the relations of the parts as to cause hemorrhage, we must continue. I recently had one case at the Philadelphia Hospital which illustrates this point. A woman had been sent to the medical ward for ascites, and had been tapped, but nothing but blood was removed. I may say here that I believe the time is coming when puncture for ascites will be a thing of the past. The patient was sent to my ward, and I made a careful examination and found a large mass completely filling the pelvis and extending up toward the umbilicus. There was some free fluid in the abdomen, which I thought was probably blood, and that she had an internal hemorrhage aggravated by the trocar. I opened the abdomen, and found it filled with blood. In my manipulations I found the hemorrhage increasing. There was carcinoma, and the only way to stop the hemorrhage was to enucleate and get a pedicle. It would not matter whether a bowel was torn or not in the removal, the only thing to do was to go ahead. That was her only chance. In another case I know of, an operation was not finished, and the patient died from the operation. In another case in which I assisted Dr. Parvin, where there was malignant disease of the ovary, there was a profuse hemorrhage; a rapid and complete removal resulted in the patient's recovery.

In regard to drainage, the majority of cases should be drained. In ectopic gestation drainage should be continued for a long time, for the parts are so destroyed by the growing ovum that there is a large amount of oozing and considerable débris to come away. There is no question in regard to the use of the drainage-tube in cases of pus tubes, and in any case where we have adhesions.

I agree with Dr. Price in regard to the operations on ovarian cysts. I think that it is absurd to allow an ovarian tumor to exist in a pregnant woman after it has been discovered. The time to operate is when the tumor is discovered; if found early so much the better.

Dr. A. B. Hirsh: As a matter of record, I wish to mention that in May I performed section on a woman seventy six years of age, for simple ovarian cyst, in which there was prompt recovery. There were no unusual features other than that the pedicle was probably an inch and a half in length. I had seen the patient only two weeks before the operation, she history being that of a slowly-growing mass, first discovered by the patient herself a year and a half previously. The operation was the classical one.

So far as drainage is concerned the pendulum seems to be swinging from the extreme of always at once closing the abdomen, to that of invariably using drainage. So far as opinion was voiced at Berlin this summer, it pointed to the universal employment of drainage. This being possibly a matter of change of fashion, the question arises as to whether the middle course would not be the one to select as we pick our cases.

Dr. Price: I gave Dr. Agnew a short history of the bowel case, and he told me that in the Wistar and Horner museums there was a large colon which had contained sixty-seven gallons of fluid. The man had died of ruptured bowel without operation.

In regard to securing a movement of the bowels, it is pretty well established that where you have peritonitis, or any condition of the bowel where peristalsis is interfered with, you have constipation from paralysis. This is most marked in cases of strangulation. In the earlier operations in these cases it was not much noticed because then the desire was to secure rest of the bowels. We now do not wish that, but begin the use of purgatives as soon as the patient rallies from the ether, and the stomach will retain medicine. I have had eight or nine cases of obstruction of the bowel, and all have recoved but one. In that case the patient was moribund when I saw him, and I operated only at the patient's urgent request. In that case there were eight inches of gangrenous intestine. In one case I had to give as much as six ounces of Epsom salts before securing a movement of the bowels, showing that the intestine was in a paralyzed condition.

There is no question as to the use of drainage. The law is, I believe, that a man should always drain when in doubt, and I always try to imagine myself in doubt. I have never seen a bad result from drainage. If you put in a drainage tube in a case where there has been adhesions, you will almost always find the belly flat; there will rarely be tympanites. A nurse who attends to these cases would far sooner take care of a case with drainage than of one without. It is folly to say that drainage is absolutely necessary in cases without adhesion. In such cases I see no reason for using a drainage-tube, although I do not believe it would do harm. Where there are no adhesions, where you can remove the cyst through a small incision, and where irrigation is not needed, I think that drainage is not called for. When in doubt always drain.

I entirely agree with Dr. Baldy that when one begins an operation he should finish it. The time to decide is when we have made the exploratory incision. I also heartily agree with Dr. Da Costa in leaving these cases of sarcoma alone. I have had one experience with sarcoma. I was called to see a man above Scranton. There were a dozen opinions that it was sarcoma. I begged the man not to have an operation. He insisted on an operation because he wanted to know what was the matter. I made the incision an inch above the upper border of the tumor, which involved the bladder, bowel, and omentum. The bleeding was excessive, and it was with the greatest difficulty that I could control it. I did not enter the peritoneal cavity within an inch of where the tumor was. If I had planted my knife over the tumor the man would never have found out what was the matter with him.

In regard to operation in apparent obstruction of the bowel, I think that we can establish a law. If we are called to a patient with apparent obstruction, with great distention and no movement probably for a week or even weeks, and that patient has no fever,

and a pulse that does not indicate any grave or serious lesion, we have no right to interfere with the knife. I was called to Chester county, to see, with Dr. Ewing, a lady sixty-five years of age, with obstruction of the bowels of eight days' standing. She had been treated with enemata and internal remedies without result. I examined her carefully and noted the stupid appearance of her face, the expression of absolute want of mental capacity which was present. There was freedom from pain and no fever. The bowels could be seen like knuckles of sausage under the skin. There was no positive indication of mechanical obstruction. I advised injection of warm solutions of Epsom salts, and the use of calomel. Before the trouble with the bowels had commenced, the woman had had a severe epileptic convulsion, and had several light attacks of the same character since. I have no doubt that the bowels were paralyzed owing to the condition of the spinal cord, or the brain, or some lesion in the abdomen of a nervous character. Under the treatment suggested she began to have free movements of the bowels, and they were thoroughly emptied. Where a man has a case of bowel trouble, or peritoneal trouble, with high temperature and thready pulse, and dose not at once proceed to use Epsom salts or other saline, provided vomiting does not occur, and attempt to get rid of the trouble, and failing in that does not go ahead and operate, does not do his duty to his patient. The moment that the patient begins to vomit anything resembling the contents of the bowel we should operate. I have never seen an abdomen opened in which something was not found to justify the operation.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

THE Sixteenth Annual Session of this association was held in Liederkranz Hall, Louisville, Ky., October 8, 9, and 10, 1890. The meeting was one of the largest and most successful of the many of that character in the history of the association. The physicians were entertained at a reception given by Drs. Yandell and Roberts; a reception at the Galt House, followed by an elegant banquet, and a number of private dinners and entertainments. The visiting ladies had several occasions arranged in their honor. Receptions, an interesting excursion to the Blind Asylum, where a concert was given by the pupils, gymnastic exercises, etc. The social arrangements were admirable, and the Kentucky belles captured more than one bachelor doctor.

The American Rhinological Association held its sessions October 6 and 7, and closed with a banquet to the members and a few invited guests.

The President of the M. V. M. A., Dr. Joseph Matthews, of Louisville, had been quite ill with blood poisoning from a wound, but was able to preside at most of the sessions; the Vice-President, Dr. C. F. Early, of Pennsylvania, filled the chair in his absence. The next meeting will be held at St. Louis the third Wednesday in October, 1891.

The officers elected for the coming year are: President, Dr. C. H. Hughes, St. Louis; First Vice-President, Dr. S. S. Thorn, Toledo; Second Vice-President, Dr. J. M. Hollister, Chicago; Secretary, Dr. E. S. McKee, Cincinnati; Treasurer, Dr. C. F. McGahan, Chattanooga. Chairman Committee of Arrangements, Dr. I. N. Love, St. Louis. Judicial Council, Dr. Murdock, Pennsylvania; Dr. H. N. Mudd, St. Louis; Dr. D. N. Griffiths, Springfield, Ill.; Dr. A. M. Owens, Indiana; Dr. Xenophon Scott, Ohio; Dr. Walker, Detroit; Dr. D. S. Reynolds, Louisville.

The address of Dr. John A. Wyeth on the Medical Student was a masterly effort, full of wit and wisdom. Prof. Wyeth graduated at Louisville, and the citizens vied with the profession to do him honor. His operation of bloodless amputation of the hip-joint was witnessed by a large number of medical men and students at the Medical Department of the University of Louisville.

Dr. Wyeth dwelt at length on the value of practical work in the acquisition of a knowledge of anatomy. He said he could shut his eyes and pick out the best men of the class by the sense of smell alone. It takes a sublime enthusiasm to enable one to forget the disgusting stench of decomposition in his efforts to master the magnificent labyrinth of bones and muscles, nerves, brain, arteries, veins, and organs which you have brought here with you to-night. He favored two sessions of purely clinical didactic teaching, and a third in which the instruction would be purely clinical. Too much time, he thought, was usually given to chemistry. For the practice of medicine, surgery, etc., a limited knowledge of the subject is all that is necessary, and that should be learned principally in the laboratory. Three months in active practical pharmacy, he thought, would be of immense benefit to the student. The nearest approach to the ideal clinical training he considered to be service as interne in a large, general hospital. The doctor, who had his first medical practice in the mountains of Alabama and the swamps of Arkansas, said that the Southern doctor could hold his own in the land of the golden calf. As proof he cited the names of Marion Sims, Emmett, Thomas, Metcalf, Bozeman, Polk, Wiley, Gibney, Gray, Dew.

The convention passed a unanimous vote, thanking its officers for their very efficient and successful work in bringing the meeting to so successful a termination.

THE PSYCHOPATHIC SEQUENCES OF HEREDITARY ALCOHOLIC ENTAILMENT

was the very interesting subject of a masterly paper read by Dr. C. H. Hughes, of St. Louis, President-elect. The doctor opened with the statement that nothing in neuropathology is plainer than the retrograde heredity of chronic alcoholics. It has been shown that the first generation shows immorality, alcoholic excess, and brutal degradation. The second one will usually show hereditary drunkenness, maniacal attacks, and general paralysis or some other similar psychopathic affection. The third generation may show sobriety; but instead of the transmitted drunkenness, the hereditary neuropathic perversion will probably reveal itself as Morel saw it, in hypochondria, mania, lypemania, and tendency to homicide and suicide; and we shall see in the fourth and after-coming generations feeble intelligence, stupidity, early insanity and the beginning of the end of family extinction. The long-continued use of alcohol as a beverage has the undoubted power of engendering neuropathic and psychopathic conditions directly in the individual, besides a great number of extra neural morbid conditions, as the oft-observed and long-doubted delirium tremens, epilepsy, insanity, imbecility, paralysis, and the neurotides of drunkards show the morbid entailments of alcoholic excess do not stop with the individual, as we have seen. They pass over in greater force to his descendants. This is the gospel of science: that the nerve mechanism which never escapes in the habitual or periodic excessive drinker, but more especially in the regular, so-called social drinker—who never sprees, though seldom refuses when asked to take a drink; who takes

his regular evening night-cap, and morning eye-opener, and tri-daily appetizer—is the vaso-motor system. This failure causes the pneumonic to die from an attack of lung fever of no greater severity of causation than that of which his non-drinking fellow in the next bed promptly recovers. We find among the drunkard's children one an idiot or imbecile, another erratic, moody, violent, visionary, melancholic or insane, epileptic, choreic, or suddenly criminal, especially among the latter offspring; while only the children born of his loins earlier in life, when alcoholic excess had made no organic impress upon him, are ordinarily healthy in mind and body.

Having made a preliminary review of what we know of the hereditary neurotic enthrallment of alcohol, he recorded an interesting hypothetical case, which he supposed to cover the facts in an important medico-legal record of detailed alcoholic disease, and crime perpetrated under its fatal sway. It is indeed a strange phenomenon of the human mind in its forensic relations, that an agent which the world recognizes and acknowledges as the parent of pauperism, insanity, and crime, and the chief direct or indirect populator of penal, eleemosynary, and correctional institutions, and the proven cause of so much disease, misery and death, should be held responsible to the extent it is before our judicial tribunals when the hapless, and often hopeless and helpless, victims of its vicious power are often arraigned to answer for crime committed through its influence over their involuntarily enslaved organisms—organisms often prenatally predestined to pathological perversion through the alcoholic excesses or other neuropathic disorders of ancestors, or through a precocious drink craving, however engendered, whether ancestrally or self-acquired, and prematurely and excessively indulged, to the harm of the delicate machinery of the brain. It is for humanity and law to decide in each individual instance, however, how far, on the one hand, inebriety should extenuate crime, and to what extent, on the other, it should punish the volition which might have engendered the disease.

The Polyclinic.

A LADY applied to Prof. Waugh for relief from a troublesome flow of saliva that had persisted, in spite of treatment, for several years. No cause could be found until it was noticed that she had her teeth filled—some with gold and others with amalgam. She was advised to have the latter removed, as it was possible that her trouble was due to galvanic action. The result is told by the patient in the following letter:

"I followed your advice and had the fillings removed from my teeth, and have been greatly benefited by it. There is now only a natural accumulation of saliva, and my general health is better, for I have not that constant feeling of nausea.

"I regret that I did not know of this sooner, as I had put up with the spitting so long, and taken so much worthless medicine, that I came to regard my case as hopeless. A. R."

"YORK, PA."

A CASE OF TETANY.—Kate B., age three, admitted August 25, 1890, suffering from tonic contraction of the muscles closing the lower jaw, and of the extensors of both lower extremities causing them to be quite rigid.

The child had been treated as an out-patient fourteen days previously for thread worms (oxyuris), these had been removed leaving the child "in perfect health" until August 23, 1890, when she fell on her knees in a playground, causing a very slight scratch on the left leg.

On the next day (24th) the child had diarrhœa—five motions, and on that evening the mother noticed that the teeth were firmly clenched.

On the 25th both legs suddenly became rigid and remained so until admission on that day.

The child was pale, fretful, teeth firmly clenched, thighs, legs, feet, and toes fully extended and quite rigid, head retracted, marked risus sardonicus when the child was touched anywhere. Temperature 98.4 F. It took milk through the clenched teeth with avidity. It was fed by nutrient enemata and by mouth with fluids, and remained in the same state until August 27.

On this day when the child was touched there was marked opisthotonos. The child was pale, and emaciating rapidly. Temperature 99.8. Urine normal. The rigidity was present when the child was asleep.

28th.—The teeth can now be slightly separated, and the right leg is a little relaxed, head retracted, neck muscles rigid. All muscles of the arms and trunk respond normally to weak faradic current, legs not influenced by strong current in any way. The child is very weak, and now will not swallow; nutrient enemata at once returned.

2 P. M.—Temperature 102.4.

The child gradually sank and died at 3 A. M., August 29. Temperature 105°2, and 45 minutes after death 105.8.

At the post mortem, ten hours after death, all muscles were relaxed. Heart, lungs, spleen, kidneys, and liver normal and healthy; intestines normal and healthy. The mesenteric glands were acutely inflamed and of a dark red color. Mesenteric veins much enlarged. No signs of peritonitis.

Spinal Cord.—There was excess of brown serous fluid in the subarachnoid space, clearly the result of hemorrhages. Brain, spinal cord, nerves and vessels of lower extremities also normal. Microscopic sections of the mesenteric glands showed masses of micrococci in the veins and many small hemorrhages. No tubercle bacilli.

Is this to be regarded as a case of tetanus or tetany?

Tetanus is rare between one and nine years of age, and nearly always begins in the jaws. Spasms and opisthotonos are common, but generally cease during sleep. Tetany generally begins in the arms or legs, is common from one to five years of age, is usually paroxysmal, and may persist during sleep, is rarely fatal; rickets is generally present. Upon the whole, therefore, the case would seem to have been one of modified tetany, fully accounted for by the mesenteric glands. The history of injury to the knee in the case is very slight, and it is difficult to understand what caused the mesenteric disturbance, which was evidently acute and not chronic in character.

The child was treated with potassi bromide and chloral, and inhalation of chloroform, but these had no effect upon the condition.—*Med. Press and Circular.*

AN ALLEGED ABORTIONIST.

NOT long ago, in an editorial entitled "Quacks and Their Methods," we drew attention to the fact that in pursuance of our duties as a medium for the advance of the medical sciences, we would always denounce, and, as far as lay in our power, eradicate quackery and malpractice in the profession.

Following this policy, a member of our editorial staff proceeded to Easton, Pa., on September 10, not only to appear as one of the leading witnesses, but also to render all possible aid to the Commonwealth in the prosecution of Dr. Howard Fackenthal for criminal abortion.

Early in May, Dr. de Lano Eastlake—now a member of our editorial staff—while in Easton, learned of the unsavory reputation of Dr. Fackenthal, and, chagrined that a graduate of one of the leading medical schools in the United States should be dubbed as a professional abortionist, determined to prove or disprove these charges by a personal investigation. At the time Dr. Fackenthal was under bail, awaiting the investigation of the grand jury for a case of abortion.

Dr. Eastlake wrote a letter, under an assumed name, in which he posed as an applicant for a criminal abortion which he wanted performed upon a "lady friend." Dr. Fackenthal answered the letter, stating that "confidence begets confidence," and requesting a personal interview. In the interview which followed, Dr. Eastlake was most careful to maintain the character of a young man in trouble, and assumed a total ignorance of all medical subjects. To his unbounded surprise, Dr. Fackenthal confessed that he made criminal abortions a specialty, offered cheerfully to relieve the posthumous female in question; said that the operation was practically painless and devoid of danger, that he had had large experience in similar cases, and finally explained his *modus operandi*, by the aid of Gray's Anatomy and several instruments.

The instruments claimed to be used by him were the uterine sound and, for advanced cases, a uterine return canula. In occasioning an abortion, Dr. Fackenthal said that he did not rupture the membranes, but, unless the case presented unusual difficulties, was able to accomplish his purpose by merely passing a sound or the canula between the membranes and the uterine wall, and, by sweeping the instrument around, loosen sufficient connection between fetus and mother to "blight its life and cause it to mature and be expelled, just as a worm blights an apple and causes it to ripen and fall prematurely to the ground." These were the doctor's words. After such an operation, he said, an abortion would follow in about five days; no immediate results would occur, and the patient might even dance the same night with impunity.

Finally it was arranged that Dr. Eastlake—or, rather, Mr. Wm. Clark, as he had called himself—should bring the woman to Dr. Fackenthal's office, ostensibly alone; that the operation should then be performed, and that a few days later he (Mr. Clark) should take the woman to some cheap hotel in Philadelphia, register as man and wife, and as soon as labor began Dr. Fackenthal should be telegraphed for, and would "see her through all right." No nurse would be needed, and the patient might be about again in ten days.

Such was the substance of the interview which was published in full in the *Medical and Surgical Reporter* at the time. The admission which had thus been secured, Dr. Eastlake naturally felt convinced should be given to the Commonwealth, and he accordingly sought the lawyer who had been retained, or said he was retained by the prosecutor of the case that Dr. Fackenthal was then under bail for.

The outlines of this case are briefly as follows: A young woman, pretty but of low mental calibre, finding herself pregnant, confided in her lover, who promised to marry her if such were her condition, but requested her to submit to an examination. This she consented to. Accordingly the young man made arrangements with Dr. Fackenthal, who was his friend, and an appointment was made. The girl did not know where she was going until in front of the doctor's office. The young man then went into the office to see if the "coast was clear," and returned shortly for the young woman. Dr. Fackenthal was found awaiting them alone. An introduction followed, and the girl was immediately ushered alone into the doctor's private office.

Dr. Fackenthal asked her if she were in the "family way." She said yes. He then asked her if she would like to get rid of the child; to which she replied, yes, if it did not hurt much. Dr. Fackenthal said it would be no more painful than an ordinary confinement, that she would not get sick for a day or two, and that the operation would be comparatively painless. In other words he made use of the same reassuring words with which he had comforted "Mr. Clark." The girl was told to lie down on a lounge. Dr. Fackenthal then took from a closet a tubular speculum and a uterine sound, and introduced first the one instrument and then the other, and causing a "sharp cutting pain." He then told her that that would be all. A week followed, but no abortion;

and the man again took the girl to the doctor's. A similar operation was performed, and again both sound and speculum used. The next day the girl was taken with severe labor, and confessed to her mother that she had been to Dr. Fackenthal. The family physician was summoned, but seeing how matters stood, refused to touch the case, and Dr. Fackenthal was called in. He reassured the mother by saying that the same man who had brought her daughter to his office had brought two other girls, and he had gotten them well, and would also get her daughter well. As it was he managed to do this, but according to all accounts the girl nearly died. She aborted a ten weeks' fetus. Dr. Fackenthal was subsequently arrested by the girl's brother and the case brought before the 'Squire. Here the above story was told. The girl identified the speculum, but as no other instrument was shown her, and as she was greatly mortified and nervous, failed to mention the sound at the time.

The defense had their own stenographer, whose record says that the girl claimed the speculum to be the only instrument used, although the 'Squire's records show that this question was not asked. The prosecutor, who is a poor workingman, also found himself in possession of a lawyer who "volunteered" to take the case.

As had been said, Dr. Eastlake, realizing the value of his evidence, sought this lawyer, but again disguised himself as a detective in search of money, in order to ascertain the lawyer's true position in the case. This was soon evident. The learned gentleman said there was nothing in the case, that the prosecutors were poor, and that if he (Dr. Eastlake) wanted to make money out of the case he had better go to the defendant. It was quite plain that the lawyer was very much in sympathy with the defendant, while confessedly working without pay for the prosecution. So Dr. Eastlake sought the district attorney, who later laid the case before one of the judges of the court, the result being that the case was taken out of the lawyer's hands and given to Mr. Merrill, one of the most scholarly and conscientious members of the Easton bar.

At the grand jury's investigation a true bill was found, largely on the strength of Dr. Eastlake's evidence, and the case came up before Judge Schuyler, of Easton. Dr. Eastlake was called as a witness, but went also as representing THE TIMES AND REGISTER, and therefore ready to render the Commonwealth all possible assistance in convicting a man who, by his own confession, made a practice of committing one of the most revolting of crimes, by which not only one life is purposely taken, but another often lost, immorality upheld, and the profession degraded. In this work Dr. Eastlake was greatly aided by Dr. Edgar M. Green, of Easton, and to him our most sincere thanks are due.

The fetus was examined both microscopically and macroscopically, and gave evidence of ante-mortem wounds or punctures—such as could have been made by a sound—on the head, shoulder, and side. A bottle of bromide solution was analyzed by Dr. Green, and found to contain seven and one-half grains to the drachm. This had been given the patient after the first operation by Dr. Fackenthal.

In the trial the defense were able to produce physicians who swore that the uterine sound could not be used through a tubular speculum, and also that a fetus ten weeks old might be born alive, and, finally, that in the determination of pregnancy the speculum was a proper instrument to use. In a word, endeavored to show that, first, an abortion could not be produced by a uterine sound through a tubular speculum; second, that if a fetus could be born alive at ten weeks the ante-mortem wounds could have been made after its birth by the fingers or nails of the physician in charge; and, finally, that when using a speculum, Dr. Fackenthal was doing what he ought to do in determining pregnancy.

In contradiction to this assertion, it was shown by the Commonwealth, aided by Drs. Eastlake and Green, that a sound could produce abortion; that it could be used through a tubular speculum, and indeed that one of the proper uses of the tubular speculum was to aid the passage of the sound. In confirmation, Simpson's Diseases of Women, page 772; Simpson's Obstetrics and Gynecology, page 618; Hewitt's Diseases of Women, pp. 74, 75; Mundé on Minor Gynecology, pp. 93 and 95; Tidy's Legal Medicine, Vol. IV, page 106; Goodell's Gynecology, page 26, and other works were quoted. Regarding the use of the sound as a means of producing abortion, Tidy's Legal Medicine, pp. 99 and 102, and Cazeaux Theoretical and Practical Midwifery were quoted. Regarding the speculum as being unnecessary and useless in the determination of pregnancy, Hewitt, Mundé and Tidy were again quoted. The impossibility of a fetus ten weeks old being born alive was shown by Tidy's Legal Medicine, p. 31. Other points of medico-legal interest were also brought up by the defense and defeated by the prosecution.

The defense then endeavored to show that the child might be born and still remain connected with the placenta by the umbilicus; and that the injuries found could have been accidentally inflicted. Our representative showed by Gray's Anatomy that neither the true umbilicus nor the maternal placenta exists at the tenth week of pregnancy, and that, therefore, the proposition of the defense was worthless. Again the defense endeavored to prove that bromide in the dose given would tend to prevent an abortion, and again Dr. Eastlake cited Pepper's System of Medicine, page 511, in which it says that during the entire course of abortion bromide of potassium or some other nervine is indicated.

In the closing speeches the counsels for the defense spent most of their time in vituperating our representative, heaping insult upon insult upon him and in endeavoring to make him out all that is bad and vicious. The prosecution did not attempt to leave the main issue of the case, but dealt with the plain evidence. The girl had gone to Dr. Fackenthal's; an operation of some sort had been performed and instruments used; a miscarriage had been the result, ante-mortem injuries had been found on the fetus which could have been made by the uterine sound, and finally Dr. Fackenthal had displayed these self same

instruments to Dr. Eastlake, while he was acting the part of Mr. Clark, and had claimed to have frequently used them in causing abortions. Such briefly were the salient points of the evidence laid before the jury, and upon such evidence they returned a verdict of "not guilty."

Although in this case justice has apparently been defeated, still we trust that abortionists, in this State at least, will hesitate before continuing their criminal practice, knowing that THE TIMES AND REGISTER is always on the sharp lookout, and will spare no pains in checking crime in the profession.

Regarding our attitude in the case, we confess that we have been most gratified at the universal appreciation of our labors in behalf of justice. The press of Philadelphia and Easton have spoken in terms of unqualified praise about the evidence and expert testimony given by our representative, and even citizens of Easton have both publicly, through the press, and privately, expressed their appreciation.

For these courtesies we are most grateful; sincere appreciation is always gratifying, and we can, in reply, only state our readiness to do any service by which we may uphold in the profession that which is honest, that which is just, that which is true, and that which is of good report; so that our lay brethren, as well as the profession, may profit by our labors.

BERMUDA.

IN a short time the rain and bleak winds of autumn will be upon us, and physicians will be confronted once more with the old but never satisfactorily-answered question, "What shall we do with our patients?" Knowing this, we do not think a few words about Bermuda will be amiss.

Among the visitors who at present frequent the Islands are a large number who will tell you they have come here to recover their health; yet, from a spectator's point of view, they present the appearonce of as healthy an aggregation of humanity as can be found anywhere. In addition to these, there is a generous sprinkling of pleasure-seekers and globe-trotters, thus placing invalids among cheerful company and doing much to divert their minds, which is an undoubted advantage.

Heretofore, when the bleak winds of winter came on, the South has hospitably opened its arms to give shelter to our invalids. Florida, the spot most favored, is unfortunately subjected to the ravages of yellow fever, and the profession has had its attention directed to Texas and California as possible alternatives, neglecting to recognize the claims of the beautiful summer islands whose proximity alone should attract their attention.

The trip takes but sixty hours from New York, and is accomplished under most agreeable circumstances. The accommodations afforded by the steamers of the Quebec Steamship Co. are all that can be desired. They are safe, comfortable, and well managed.

The climate, like all semi-tropical resorts, has its variations. The changes recorded by the thermometer are so small, however, in comparison to those we experience in the North and West, that they pass entirely unnoticed after one has become acclimated. The worst evil which winter entails is rain, and even then it is rarely more than a hard shower. Several consecutive days of rain, as we have so often experienced in the last few years, is of rare occurrence.

Moreover, the rain causes but little discomfort, on account of the coral formation of the islands, which absorbs the water with sponge-like rapidity.

During the past ten years the average minimum temperature at night, or in shade, from December to May, was from 55° to 65° F.; while the average maximum temperature in the same time was from 68° to 77° F. The highest temperature reached during the same period was 80°, which is unusual.

The record of the winter of 1889 and 1890 shows the following temperatures:

	Highest.	Lowest.	Mean.
December	73	58	65.27
January	71.5	52	64.03
February	72	49	63.88

In February the thermometer fell to 49° at 10 P. M. This was the coldest night of the winter, and those well posted say that it was the lowest they have ever known the thermometer to register.

Bermuda is situated in the 32d parallel of latitude, and it is a mistake to suppose that the islands are thoroughly tropical either in appearance or climate. The atmosphere is genial and pleasant.

The barometer usually registers from 30 to 30.7, and rarely, even during a storm, falls to 29. Competent resident physicians claim that the climate is beneficial for the following diseases: (1) Nervous prostration. (2) Genito-urinary troubles. (3) Chronic rheumatism and gout. (4) Dyspepsia. (5) Convalescence from acute or other affections.

There are numerous comfortable hotels and boarding-houses where the prices are reasonable, besides several large and luxurious hotels where charges are, of course, much greater.

Bermuda is a charming place at all seasons, and is exempt from the ennui of many sub-tropical retreats. The pastimes indulged in by the Bermudians include almost every kind of out-door sports, from tennis to yachting. Besides there is excellent sea-bathing all the year around, the water being often warmer than the air. Riding and driving are the amusements most indulged in. The perfect roads and low charges by the liverymen have done very much to popularize them. With regard to the novel scenic attractions, there are but few Northerners who will not be enchanted with the diverse effects. There are numerous points from which fine views can be had. One of the most beautiful and striking sights is the Easter lily fields, whose crop adorns many of our churches on Easter day.

The change from a temperature which fluctuates 40° and 50° in a day; the invigorating atmosphere; the delightful sociability of the place; the absence of protracted rain, and the novel scenery, both landscape and marine, all contribute to assure the future of this spot of concentrated loveliness as one of the most popular sanitariums of America.

Annotations.

IN the *New York Medical Times* we find a paper presented by W. M. Decker, M.D., to the New York Homœopathic State Society, entitled Some Therapeutic Principles, Now and Previously Held by the New School of Medicine, which are Unsound. The article concludes as follows:

The following resolutions offered at the conclusion of my paper were tabled, the society thereby putting itself on record as not ready to denounce these untenable theories of Hahnemann:

Resolved, That in the opinion of this society the theory of potentiation of drugs, as taught by Hahnemann in the "Organon" and in his other writings, that is, the doctrine that the more drugs are attenuated by successive trituration, or the more they are diluted or succussed, the more their power and effectiveness is increased, is hereby declared unsound and unreasonable in principle, except the fact that division of drug matter is accomplished.

Resolved, That all symptoms attributed to provings with high potencies are of doubtful reliability, and therefore they are not trustworthy guides in practice.

Resolved, That, in the opinion of this society, the theory of the psoric origin of chronic diseases, as set forth by Hahnemann in the "Organon" and in his other writings, is erroneous; and, therefore, as a basis for treatment, it is misleading.

Resolved. That, in order to prepare for intelligent action on the foregoing resolutions at the next annual meeting of this society, the bureau of Materia Medica is hereby authorized to compile and issue an abstract of its report for distribution to the members of this society.

A. LAPTHORN SMITH calls attention, in the *Canada Medical Record*, to the absorption of drugs from the vagina. He has noted this when using iodine, iodoform, and corrosive sublimate. With the latter, the post-partum introduction of a pint of 1 to 1,000 solution was followed by sudden diarrhœa, collapse, and suppression of urine. He inclines to the belief that this absorption takes place even when the membrane is unbroken. He says:

"I have now been employing the local administration of bichloride of mercury in doses of one-tenth of a grain every three or four days, on a boro glyceride tampon, during the last two years, about five hundred times in about fifty cases of vaginitis, endometritis, salpingitis, ovaritis, and pelvic peritonitis, and I feel sure the duration of treatment, before relief has been obtained, has been very much less than was the case before I adopted this method. Exactly how much of my success is due to the bichloride alone, I am unable to say, for the simple reason that, at one time or another of the treatment, in every case, I employed other remedies and measures in addition to it. One of my reasons for attaching so much value to the bichloride of mercury employed in this way is, that nearly every one of the diseases above mentioned is due more or less directly to septic absorption, and that the more or less constant production of septic matter is necessary to keep up the disease."

AFTER laughing at Chinese warriors for several centuries for their use of stinkpots as weapons in battle, Christendom has suddenly awakened to the fact that there may be something in the idea. "In a sham fight at Portsmouth an advancing column was so affected by the fumes of the smoke-ball, which was used to raise a cloud of impenetrable obscurity under which they could advance, that the men had to keep their hands to their noses to avoid suffocation. It is now proposed that the smoke-ball shall receive a further development. It has occurred to some military men that instead of half suffocating their own troops it would be better to follow the example of the Chinese pirates with their stinkpots, and asphyxiate the enemy. A Vienna scientist has accordingly invented a bomb of such power and virulence that every one who is within a certain radius of it when it explodes is rendered unconscious. Devices such as these would soon modify the art of war, and probably the next development will be an anti-asphyxiating bomb whose fumes will neutralize those of the other. It is said that many years ago a scheme based on the throwing of poisonous gases over a tract of country was put before the war office in England for the purpose of devastating the country in the face of an invading army, but the agency employed was so terrible in its effects that it was not made public and was consigned to the secret records of the war office."—*Chicago Daily News.*

TREATMENT OF TYPHOID FEVER.

IRVIN, in the *American Practitioner and News*, contributes a paper on typhoid fever, the summary to which we quote as an example of the extreme slowness with which new ideas penetrate the professional mind. Scarcely one of his propositions is tenable, and the resort to opium for every emergency reads like one of the "Tales of a Grandfather." We quote:

1. There is no medical treatment for an uncomplicated case of typhoid fever.

2. Diet and stimulants carefully regulated to suit the case, and good nursing, fulfill all the indications.

3. The fever is best controlled by frequent sponge baths of tepid water and alcohol, and the internal use of stimulants and opium.

4. Feeble heart and prostration from hemorrhage or diarrhœa are relieved by opium, stimulants, belladonna, and oxygen gas.

5. Pneumonitis and bronchitis are not influenced by special medication. Food and stimulants, with opium to relieve cough and pain, and quinine in tonic doses may be given.

6. Hemorrhage of the bowels requires the free internal use of opium only.

7. Perforation of the bowels is only successfully treated by the use of opium.

8. Peritonitis requires the use of opium in repeated doses.

9. Tympanites is most successfully relieved by the use of opium internally three or four times daily, with turpentine applied to the abdomen.

10. Diarrhœa is controlled by opium and the regulation of food.

11. Insomnia yields best to the use of opium; where this drug is not well borne codeine paraldehyde or urethan may be given.

12. Nephritis should be poulticed locally and opium given internally to relieve pain.

13. Constipation is best relieved by mild laxatives and enemata.

Retention of urine requires the use of the catheter only.

TEXT-BOOKS ON OBSTETRICS.

"OF making of books there is no end"—no doubt more applicable at the present time than when first uttered. Authors appear one after another in such rapid succession that neither student nor physician can find time for the careful perusal that it is expected will be given the various works.

From the necessities of the case all are characterized to a large extent by lack of originality, excepting in general arrangement and expression, being more or less compilations and transpositions of what has been already written.

Of the elaborate works on Obstetrics at the present time, that of Cazeaux and Tarnier is perhaps the most complete, and is well worth the student's leisure hours. As a work of reference Edgar's edition of Winckel is excellent. The works of Parvin and Lusk are useful to students and practitioners. Galabin lacks systematic arrangement, but in other respects is a good text-book.

For the student Playfair will be found to give still most satisfaction, owing to the systematic arrangement of its subject-matter and conciseness of statement. Among the smaller works Stewart's Synopsis is the most complete hand-book of reference for student's use.

It would seem that the time has about come when instructors and authors should form an association which might appoint from its number various capable members, eminent specialists and talented writers, who shall be the authors of the recognized text-books of the future. Their first work should be accurate compilations of the knowledge which exists, but is to some extent lost either by scattering throughout various works or by the confusing want of uniformity in nomenclature, classifications, measurements, etc. From time to time the needed revisions could be made, and the newer ideas and later discoveries incorporated.

The great number of text-books on each subject published at the present time adds undoubtedly to the prices of all works, as each new one meeting with favor interferes more or less with the sale of others, and no sooner is one book recommended to the student and secured by him than another appears and claims his attention.

The enormous expense incurred by the public schools from year to year through the frequent changes of text-books is a familiar instance of this, in some measure at least, unnecessary outlay.

Letters to the Editor.

PIRATICAL PUBLISHERS.

THERE is probably nothing which excites greater indignation amongst literary men than the unauthorized reproduction of their works.

May I beg your assistance in exposing a gross case of publisher's piracy, of which I have the misfortune to be one of the victims?

In November last I published here and in London a book on the Treatment of Chronic Bronchitis, the result of ten years pretty hard work at the Westminster Hospital. I printed it at my own cost, and went to considerable expense in the matter of illustrations. I made a satisfactory arrangement with my old friends, Messrs. P. Blakiston, Son & Co., of Philadelphia, for the issue of an American edition, which appeared in due course. I have just heard from them that it has been "pirated," I believe that is the polite expression, by Messrs. Wm. Wood & Co., of New York, who have reprinted it not only without asking my permission, but without communicating with either my American or English publishers. It appears that there are now firms in New York who appropriate the property of their trade colleagues with as little compunction as they do that of British authors. This is certainly a new departure in journalism, and one which should be more widely known.

On looking over Messrs. Wood & Co.'s list of recent publications I came across the names of several of our best known English writers, and I was anxious to learn how they had fared. I accordingly placed myself in communication with about a dozen of them, and the result has been a storm of indignant letters; the authors, one and all, complaining that their works had been disgracefully pirated.

Sir Henry Thompson says: "I had not heard of any reproduction of any work of mine by Messrs. Wood & Co., of New York, until you named it."

Mr. Bryant says: "I had no idea that my book had been reprinted in America. It has certainly been done without my permission."

Dr. Dickinson says: "The information in your letter that Messrs. Wood have reprinted my lecture on the Tongue is new to me. They did the same for my book on Urinary Diseases. I have of course given no permission."

Dr. George Harby says: "I am grieved to find that Wood & Co. are among the publishing pirates, and am surprised to learn that they are about publishing some of my writings."

Mr. Jonathan Hutchinson says: "I certainly never gave any permission to Messrs. Wood & Co. to reprint my Pedigree of Disease. In a recent Atlas of Skin Diseases a large portion of the plates are mine without, so far as I can find, a single word of recognition."

Mr. Richardson says: "Wood & Co., of New York, not only pirated my entire essay, but did so in face of my protest."

I have received similar communications from Mr. Keetley, Mr. Mark Hovell, Dr. Simon, of Birmingham; Dr. Sinclair, of Manchester; Dr. Whittle, of Brighton; Dr. Theis, Dr. Lloyd Tuckey, and many others.

The only exception appears to be in the case of Dr. Currie, of London, who states he was offered a small percentage on the sale of the book, but adds significantly that up to the present he has not received it.

There is, I understand, an impression in America that Messrs. Wood & Co. pay the authors whose works they appropriate, but I cannot find that there is any foundation for this belief. I have talked the matter over with many of my American friends—authors and others—they are naturally indignant at the treatment we have received. I have always met with such kindness and courtesy from my colleagues on both sides of the Atlantic that I hope they will assist me in exposing such unworthy tactics. I am told that there are English publishers who pirate the works of American writers, and, if this is the case, I trust no diffidence will be felt in mentioning their names. I for one have no sympathy with the wrong-doers.

There is, unfortunately, at present no International Copyright Law, and presumably we have no legal redress, but a little wholesome exposure may serve to bring Messrs. Wood & Co. and their friends to their senses, and make them understand that there is such a thing as fair dealing, and that a departure from the recognized rules of commercial integrity does not pay in the long run.

WILLIAM MURRELL.
WEYMOUTH STREET, Portland Place, London, England.

MUCH interesting matter may be found in this weeks' advertising pages.

Cincinnati Letter.

THE Cincinnati delegation to the Mississippi Valley Medical Association was the largest and most numerously represented on the programme of any of the cities represented at Louisville. They all seem to be quite well pleased with what they heard, saw, and tasted in the Kentucky metropolis. Those who did not get to go were great losers.

Dr. B. Knox Ratchford has returned from Berlin where he has been spending some months paying special attention to pediatrics.

The many friends of Dr. Robert Bartholow in this city, hear with much regret the report of his ill health and retirement.

The South Western Ohio Medical Society had the good sense to adopt a constitution and by-laws modeled after that of the Mississippi Valley Medical Association, thus excluding medical politics, one of the greatest clogs to medical science.

Dr. W. W. Dawson has been suffering for some time a second attack of la grippe, which his many admirers deeply regret.

One of Cincinnati's batchelor doctors could scarcely tear himself away from Louisville's fair ones, and has the credit of being the last one home. He said he was making investigations as to the prevention of myopia.

Dr. J. B. Cromly will soon remove to New York, where he will practice in the future.

Dr. J. C. McMechan is responsible for an interesting story on cremation. The vessel was not quite large enough to hold the remains of his patient, and the devoted wife, not wishing to waste any of her beloved's ashes, placed the rest in an unused pepper-box. One day the cook, in a flurry preparing dinner, found the pepper-box and peppered the roast beef. As something seemed wanting about the beef the mistress of the house inquired if it had been peppered. The cook insisted that it had, and to prove it produced the identical pepper-box, which contained a part of the ashes of the departed head of the house. Which part the doctor does not say.

The South Western Ohio Medical Society met in its regular semi-annual session at the Burnet House, Cincinnati, October 16 and 17, 1890, with the President, Dr. J. C. Reeves, of Dayton, in the chair, and the Secretary, Dr. Willis W. Hall, of Springfield, at the desk. The address of welcome was made by Dr. J. T. Whittaker, of Cincinnati. The doctor welcomed the visiting doctors most warmly, then went into the consideration of two diseases which especially merited consideration, to speak only from the standpoint of internal medicine, one local, the other general, both attended with great mortality, as the most frequently encountered, and both as a result of recent study entirely preventable, viz.: typhoid fever and tuberculosis.

Typhoid fever we now know to arise wholly and exclusively from drinking water contaminated with the feces of typhoid fever patients. We get it plainly in our city from infected river water, and the lesson we are taught every year cries louder than the water famine of a single year for reformation in this regard. Nature has kindly lifted for us, in our immediate vicinity, great natural basins for reservoirs, on the adjoining hills of Kentucky, above cities which are in reality but suburbs of our own, across a river which will soon be bridged at every block—and all that is needed is pumping stations higher up the river at sources of more pure supply. From large receiving basins on the Kentucky shore, wherein the water might remain a week or more to settle, the streams may be conducted over a viaduct to our present basins as centers of distribution.

The typhoid bacillus does not live long in fresh water—according to recent investigations, not longer than a week—and whatever germs of disease are present would gravitate to the bottom of the lake, if quiescent, to be removed with other refuse when the basin is cleared out and cleaned. The objection of the ward politician that our sister State might some day be an enemy, is easily met by the preservation of our present works for such a dire emergency.

Tuberculosis we have always with us as a result, almost wholly and solely, of contamination of the air by dried, disseminated sputum. The spectre of heredity has now disappeared entirely from the etiology of this disease, with the observation that the children of tuberculous parents, removed from danger of infection, entirely escape the disease. Advanced tuberculosis in parents never produces the disease in the new-born, for the simple reason that the essential elements of a fecundation never show or contain the tubercle bacillus. This disease is not congenital, but contracted, acquired after birth by breathing in an infected air. All that is necessary to prevent the dissemination of this disease is to keep the sputum moist, to use cuspidors and cups half filled with water, to be emptied daily in drains, which, in turn, empty into running streams.

No particulate bodies can possibly arise from moist surfaces. This particular law simply contains all the essence of prevention in the case of this disease.

The doctor next described the various agents used to limit the growth of the bacillus in the body of man, and made mention of the recent discoveries of Koch with the cyanide of gold, and more especially with the salts of cobalt, which would prevent the inoculation of the extremely sensitive guinea-pig, or check the advance of the disease in animals inoculated before. Every clinician and every pathologist believed that the time was near at hand when some agent would be found to destroy, or more especially to check, the growth of the tubercle bacillus in the body, without damage to the cells and tissues of the body. The doctor did not believe the recent telegraphic dispatches to the effect that Koch had abandoned his experiments concerning the cure of tuberculosis.

Peritonitis was the subject of a paper by Dr. Dan'l Millikin, of Hamilton. The doctor laid special stress on the symptoms, a very pointed one being pain. The patient lies on his back, with knees elevated, and soles of feet applied to the bed. This is done to prevent the bedding from touching the exquisitely tender abdomen. Abdominal respiration is abandoned, and shallow respirations take their place. If there be any cough the patient makes every effort to suppress it, on account of the severe pain it causes. Vomiting is an early symptom, and food is violently ejected. Diarrhœa is rare, but constipation frequent. The abdomen is retracted in the earliest stages. In the later stages the intestines become distended, and the abdominal muscles yield. The pulse is frequent and small. Respiration runs as high as 40 per minute. Average temperature runs as high as 101.5° F. The countenance is anxious like a wild animal in a trap. The mind remains clear throughout the disease. The pallor is a peculiar feature, and death comes with decline of pulse and temperature. The doctor spoke of the great variation in the symptoms of the disease, and remarked that some cases were so

masked that they went on to death, and the disease was only diagnosed on the post-mortem table.

The treatment of the insane was the subject of a paper by Dr. A. B. Richardson. He advised the establishing of a hospital for the treatment of the curable insane of the country, to be under the care of a special staff, also a consulting staff of physicians and surgeons. He urged the better teaching of students with regard to the treatment of insanity.

The Surgical Treatment of Epilepsy was discussed by Dr. B. M. Ricketts, of Cincinnati.

Headaches by Dr. Philip Zanuer, of Cincinnati.

Chloroform was the subject treated by Dr. H. N. Brown, of Hillsboro. He considered this a safe anæsthetic, but its safety lay in its administration.

Sympathetic Ophthalmia was the subject treated of by Dr. S. C. Ayres, of Cincinnati.

Hysterical Paraplegia in a Child was the subject of a paper by Dr. S. P. Deah, of Potsdam.

Cæsarian Section, with report of case, by Dr. J. N. Bartholomew, Trenton.

Cardiac Diseases in Soldiers, Dr. F. H. Patton, National Military Home, Dayton.

Delayed Operations in Ovariotomy was the subject treated by Dr. Rufus B. Hall, Cincinnati.

Chloroform and the Hyderabad Commission was the subject of the President's address, by Dr. J. C. Reeve, of Dayton, a national authority on anæsthetics. He handled the Commission, their sins of omission as well as commission, without gloves; denying, and apparently proving his denial of many of the points of their report.

The officers of the society elected were as follows: President, Dr. Dan'l Millikin, of Hamilton; Vice-Presidents, Drs. S. P. Deah, of Potsdam, and R. T. Trimble, of New Vienna, Vernon; Secretary and Treasurer, Dr. W. W. Hall, Springfield. Next place of meeting, Hamilton, April, 1891.

The society adopted a constitution and by-laws copied largely from those of the Mississippi Valley Medical Association.

Book Notices.

THE MEDICAL STUDENT'S MANUAL OF CHEMISTRY. By R. A. WITTHAUS, A.M., M.D. Third edition. New York: William Wood & Co., 1890.

The advances in chemistry are exemplified in the necessity for a third edition of this book within seven years. In the present edition the sections on chemical physics and mineral chemistry contain much new material. The carbon compounds have also required special attention; this chapter having been largely rewritten. The book now forms a handsome volume of 528 pages, with a strong and durable binding.

A TREATISE ON THE DISEASES OF INFANCY AND CHILDHOOD. By J. LEWIS SMITH, M.D. Seventh edition, thoroughly revised. With fifty-one illustrations. Philadelphia: Lea Brothers & Co., 1890. Cloth, 8vo., pp. 900.

It has been four years since the sixth edition of Dr. Smith's work was issued, and in that interval "many additional facts have come to light relating to the etiology, nature and treatment of the diseases of children." In all the departments the work shows evidences of revision done with Dr. Smith's conscientious thoroughness. The author is at all times the tried and trusty practitioner; judicial rather than enthusiastic, and one feels that his approval is not given without being earned. We look upon this as the best of our American works upon children's diseases; and as such recommend it to our readers.

WOOD'S MEDICAL AND SURGICAL MONOGRAPH. Vol. VIII, No. 1. October, 1890.

Contents: Suppuration and Septic Diseases, by W. Watson Cheyne, M.D.

Pharmacopœia for Diseases of the Skin, by James Startin.

The Nasal Neuroses, by Granville Macdonald, M.D.

Artificial Respiration: The Theory and Practice, by Benj. W. Richardson, M.D.

The Newborn Infant: Its Physiology, Hygiene, and Nourishment, by Dr. A. Auvard.

The Urine in Neurotic Diseases, by Dr. Alexander Peyer.

THE LATIN GRAMMAR OF PHARMACY AND MEDICINE. By D. H. ROBINSON, Ph.D., and L. E. SAYRE, Ph.G. Phila.: P. Blakiston, Son & Co., 1890. Cloth, 12mo, pp. 271.

Our constant readers will have noted how frequently we have had occasion to criticise the Latin of prescriptions, in books noticed. How bad is the Latin generally used by physicians, no man can conceive, unless he has inspected the prescription files of a pharmacy. While a book like this will not make a scholar of one who has no previous knowledge of Latin, it will at least enable him to use correctly what he requires in reading or writing prescriptions. The difference between this and any ordinary Latin grammar is that in the book before us the examples are words used in medicine; such as tussis, sulphas, etc.; so that the student learns a little of his own spec al profession with his Latin. A short vocabulary is attached. Designed for students who wish to get up their Latin in a hurry, it accomplishes its purpose admirably.

A TEXT-BOOK OF COMPARATIVE PHYSIOLOGY, for Students and Practitioners of Comparative (Veterinary) Medicine. By WESLEY MILLS, M.A., M.D., D.V.S. With 476 Illustrations. New York: D. Appleton & Co., 1890. Cloth, pp. 636.

As teacher and practitioner, Dr. Mills has earned the right of having and expressing views upon his specialty. Works on equine physiology are rare; since there are but two others printed in English, and those only appeared within the last year. And yet, a knowledge of this subject appeals to man in his most sensitive spot—the pocket. It seems singular, when one thinks of the vast interests involved in the breeding and care of stock, that veterinary students should be compelled to view their subject through the medium of works on human physiology alone. The present work treats of general biology, reproduction, development of the embryo, chemistry of the body, the blood, contractile tissue, muscle physiology, nervous system, circulation, digestion, respiration, the skin, the kidney, metabolism of the body, the spinal cord, brain, special senses, voice, and locomotion. The cuts are excellent and plentiful; the book will be found of value by all who desire a concise manual of comparative physiology.

Pamphlets.

Proceedings of the National Conference of State Boards of Health at the Seventh Annual Meeting held at Nashville, Tennessee, May 19–20, 1890. Published for the State Board of Health of Pennsylvania.

Functional Albuminuria; or, Albuminuria in Persons Apparently Healthy. Read before the American Medical Association, by William B. Davis, A.M., M.D., of Cincinnati.

Annual Report of the Health Commissioner of St. Louis, Missouri, for the fiscal year ending April 7, 1890.

A Study of the Anæsthesias of Hysteria, by Charles L. Dana, M.D. From *The American Journal of the Medical Sciences.*

The Medical Digest.

FRENCH NOTES.

By A. E. Roussel, M.D.

Surgery of the Nervous Centers.—(Berlin Congress; M. Horsley, of London).—Operative intervention is indicated in each case when we find ourselves in the presence of a traumatic lesion involving the brain, principally in young subjects, if the lesion does not cause epilepsy or mania it may very well cause arrest of development. In cerebral hemorrhage an immediate intervention may prevent thrombosis and its consecutive paralysis. This intervention consists in the ligature of the primitive carotid. The author has performed this operation twenty times, and his experimental researches on the subject have proved to him that this ligation completely arrests the hemorrhage in the region affected. Trepanation in cases of meningitis has not been followed with success in pachymeningitis; excision of fragments of the thickened dura-mater may be productive of some results, but it is especially in cases of localized diseases, tumors, Jacksonian epilepsy, that surgical treatment promptly applied has produced good results. Cerebral gummata are, according to the author, subject to the same treatment, specific treatment being insufficient to cause their total disappearance.

The mortality of trepanation is 20 per cent. Trepanation of the vertebral column, indicated in puncture of the vertebræ with symptoms of compression of the cord, is a difficult operation, offering but few chances of success.—*Revue de Therapeutique.*

Identity of Human and Animal Diphtheria.—M. Delthil presents the following conclusions: All goes, therefore, to prove that the diphtheria of animals, whether coming from mammals or more especially from the ornithological race, is analogous to that of man, that it is transmissible from animal to man and *vice versa.* It results, therefore, that we should carefully watch, in point of view of contagion, the animals of our stables and yards, as well as inspect the markets.

This opinion is becoming more generally accepted day by day in France, in Germany, in Italy and in Switzerland.—*La Médicine Moderne.*

Epilepsy of Nine Months' Duration Following Dental Caries.—M. Bakowski reports the following cure of reflex epilepsy: He was called on the 15th of May, 1889, to attend a young girl of sixteen years whom he found in an epileptiform attack. Notwithstanding varied treatments (bromide of potassium, quinine, arsenic), the attacks continued; they were accompanied by loss of consciousness and were repeated several times a day. At the end of the month of December, 1889, M. Bakowski had his attention attracted to the teeth of his patient. The first upper molar on the right and the first inferior molar on the left were decayed. The patient did not suffer from the above; but immediately before each attack she experienced a sort of a disagreeable sensation (*aura epileptica*). These teeth were removed, and since this time the attacks have no longer returned. This cure has now continued for six months.
—*La Bulletin Médical.*

Correlations of the Sexual Functions and Mental Disorders of Women.—Barnes (*Med. Press*) thus concludes a paper on this subject:

I may conclude this imperfect presentment of a great theme by stating what seems to be the logical sequence of the facts and arguments set forth.

The proposition I present is, indeed, self-evident. All the resources of medicine, special and general, should in every case be brought to relieve the sick. This implies that similar direct objective investigations as that which is pursued in the case of females suffering from sexual disorder not apparently complicated with nervous disorder, shall be made in the subjects of nervous disorder in whom there is reason to infer that sexual derangement exists.

In the first place, there is the immediate indication to seek for light as to the cause of the nervous disorder, with a view to relieve this complication. In the second place, even if the nervous disorder be found not to depend upon the sexual disorder, it is still the duty of the physician to do what he can to relieve the sufferer from this element of trouble. An insane woman has surely as much right to relief from disease of the ovaries and uterus as a sane woman has.

Griesinger (1867) speaks very decidedly upon this point. He says: "On the least suspicion, a local examination should be made. It is certainly of great detriment to the patients that there exists amongst the asylum physicians a truly childish delicacy in regard to vaginal examinations. In Germany, France and England, I have found the same delicacy; they seem to be afraid of exciting the patients." This was said in 1867. I think the censure may now be considerably modified.

One rule I strongly urge. In every case of puerperal insanity, examine into the condition of the pelvic organs. Imperfect involution of the uterus is in the highest degree probable. In addition to other factors the functions of the breasts are almost always suspended. Thus a most potent stimulant to involution is wanting. Then retroversion or retroflexion is very probable. Relief from these conditions cannot fail to be beneficial, and may even bring about recovery.

Thus we see that in this inquiry the physiologist and the gynæcologist meet on common ground, each enlightening the other; and both helping to build up out of the materials of their special knowledge that true science, that comprehensive medicine which holds out the best prospect for the relief of physical and mental suffering.

Fatal Dyspnœa Due to a Caseous Gland.—The patient was an infant in arms, and previously to the onset of the dyspnœa was believed to be in perfect health. Suddenly, and without any obvious reason, the baby was seized with urgent dyspnœa. On admission, the house surgeon explained the dangerous condition to the mother, and that tracheotomy might be necessary at any moment. The mother, however, would not consent to any operation without first consulting her husband, and went away for this purpose. Meanwhile, the dyspnœa became extremely urgent, and tracheotomy was performed by the resident medical officer without the parents' consent. Some temporary relief was afforded; but a foreign body which was believed to be the cause of the trouble could not be found, nor any other satisfactory explanation for the dyspnœa. The child died within one and a half hours of the commencement of the attack. At the post-mortem examination a caseous gland, which had ulcerated its way into the trachea, was found just above the bifurcation, occluding one bronchus entirely. There had been no symptoms to attract attention to such a condition.—*Med. Press.*

ADULTERATION IN FOODS AND DRUGS.—Dr. Newton, Dairy Commissioner of New Jersey, reports for the past year that of 2,507 articles of food analyzed, 1,102, or 43.96 per cent., were adulterated. While all the American canned goods examined were found in good condition and free from metals or other dangerour ingredients, 88 samples, out of 107, of foreign canned goods were adulterated, the chief adulterant being copper, which had been added to give a green color. Three-fourths of the samples of extracted honey analyzed were adulterated with glucose or cane-sugar syrup. More than half of the molasses specimens were adulterated with molasses or cane-sugar; and what was sold for molasses was glucose and contained tin. Seventy per cent. of the pickles contained copper; seven samples of baking powders contained alum; raspberry syrup contained no raspberry, but in its stead an artificial ethereal flavoring essence colored with an aniline dye; and sausages were dyed with Bismarck brown and garnet red, and coated with a varnish composed of shellac, resin oil, and alcohol. Jellies, however, bore off the palm. Of 192 samples, 159 were adulterated; starch, water, acetic acid, currant flavoring extract, glucose, and coloring matter masquerading as currant jelly. In Philadelphia one manufacturer sold thirty-nine tons of this stuff in a single week, while another delivered one thousand tons in six months. Fifty factories are engaged in this business in this country.

Of the drugs examined, 64.55 per cent. were found adulterated or not equal to the standard. The fraudulent list included cream of tartar, opium, paregoric, iodide of potassium, seidlitz powders, spirit of nitrous ether, laudanum, and tincture of chloride of iron.

—*Brooklyn Med. Journal.*

Medical News and Miscellany.

PHILADELPHIA streets are unusually dirty.

DIPHTHERIA still exists at Bridgeton, N. J.

DIPHTHERIA has become epidemic in Indianapolis.

OSMAN, of Cavallovit, Turkey, is said to be one hundred and sixty years old.

THE bad quality of the potatoes at Killarney has produced an outbreak of fever.

THE public school at Center Grove, N. J., has been closed on account of diphtheria.

DR. JOHN S. MILLER, of Philadelphia, last week trephined a man for traumatic epilepsy.

DR. E. B. MATTHEWS, of Mobile, Ala., claims to have the largest rosebush in the world.

DIPHTHERIA has appeared in the southern part of Chicago, at Hyde Park and Homewood.

SOMETIMES a man becomes such a victim to drink that even the hopes of his friends are dissipated.

AN unfortunate Swede is confined in the Chester pest house, supposed to be affected with leprosy.

AUNT EDITH WILSON, of Providence, Kentucky, is said to be one hundred and thirty-three years old.

IT is proposed to employ the phonograph to take down the utterances of drunken men, that when sober they may realize what fools they have made of themselves.

NUSSBAUM, the celebrated Bavarian physician who died last week, is said to have been an opium habitue.

DURING September the deaths in St. Louis numbered 710; representing an annual mortality of 18.73 per 1,000.

DR. CHAS. B. PENROSE has been elected surgeon to the German Hospital of Philadelphia, to succeed Dr. F. H. Gross.

DR. W. B. COSTILL, of Trenton, has been made the defendant in a divorce suit, but emphatically denies the marriage.

COPIES of Dr. Frank S. Billing's paper on Inoculation can be obtained on application to the author, 134 Rialto Building, Chicago, Ill.

BLACKENING the nose and cheeks under the eyes has been found an effectual prevention of snow blindness and of the glare from snow.

DR. C. C. CROLLY, of White Plains, N.Y., endeavored to commit suicide on the graves of his two children, recently dead with diphtheria.

THE American Academy of Medicine will hold its next annual meeting at Philadelphia, Wednesday and Thursday, December 3 and 4, 1890.

DR. CHARLES MEIGS WILSON has resigned his position as physician to the Lying-in Charity, at Eleventh and Cherry streets, Philadelphia.

PROF. HOLDEN, of Lick University, claims to have discovered on the moon parallel walls two hundred feet thick and twelve hundred feet apart.

DR. QUINDARO MCQUAIDE, lately of the Norristown Asylum, has opened an office in Dr. Duer's former residence, at 1704 Arch street, Philadelphia.

WHEN certain foods disagree, it is better to lessen the quantity than to forbid them altogether.

—Sir William Roberts.

THE new wards of the Presbyterian Hospital will be ready for occupants on Thanksgiving Day; which has been designated as Donation Day by the Managers.

THERE is some trouble between the nurses and residents at the Philadelphia Hospital; due to the division of authority between the Chief Resident and Head Nurse.

DR. A. P. HELLER, of Millville, Pa., died last week, after practising in Columbia county for over forty years. He left a large estate. He graduated at the Eclectic Medical College, of Philadelphia, in 1854.

THE "all watches are compasses" item is destined to go the rounds. It may be that "when the hour hand is pointed towards the sun, the south is exactly half way between that and the figure xii," but on which side?

THE new Industrial Home for Girls and Women was opened November 3, at 425 South Thirteenth street, Philadelphia. It is intended as a shelter for women out of work, where they can earn something and keep straight.

DURING October there were 33 admissions to the Germantown Hospital, 30 discharges, and 2 deaths. In the dispensary 284 medical and surgical cases were treated; also 204 eye and ear cases; total, 488. There were 22 ambulance calls.

DONATION DAY at the Philadelphia S. P. C. A. realized over $400. During the past year the society investigated over 11,000 cases of alleged abuse. We regret to hear that this most worthy society is not in good condition ; the membership is decreasing yearly.

DURING October, 34 medical cases were admitted to St. Mary's Hospital. In the dispensary there were 1,901 visits paid by patients, among which were 426 new cases, 175 accident cases, 100 eye cases, 95 ear, nose and throat cases, 51 medical cases, and 40 surgical cases.

RUSSIA now allows female physicians to practise in all parts of that empire. They will wear a badge of their profession, and can practise in female schools and institutions admitting women, in similar institutions of the Zerustvos, and are specially exempted from calls as experts to attend criminal trials.

IN Southern California are Indians said to be from one hundred and fifteen to one hundred and forty years of age. They are said to have lived very temperately, their food being acorns, flour and water. Whether they or the world are any better off than if these people had died at the early age of seventy, is not stated.

A NOTICE was sent to the newspapers Saturday night stating that Prof. Bartholow had been offered the chair of materia medica and therapeutics in the Pennsylvania College of Pharmacy, and when installed he would be the dean. Prof. Bartholow said he knew nothing about it, and if offered the place he would not accept it.

AT the annual meeting of the contributors to the Gynecean Hospital, held recently at the office of J. Sergeant Price, the following officers were elected: Governors, Alexander Biddle, Dr. R. A. F. Penrose, J. Sergeant Price, Dr. William Hunt, Edward H. Trotter; President, Alexander Biddle; Secretary and Treasurer, Edward H. Trotter.

THE *Alabama Age* states that the law regulating registration in that State was so curiously worded that, though the Supreme Court has decided that illegal practitioners are criminals, they cannot be punished. An effort is being made to remedy this omission, but is opposed by the practitioners who do not belong to the regular school.

THE following were the operations of the Pennsylvania Eye, Ear and Throat Infirmary, northeast corner of Thirteenth and Chestnut streets, during October: Eye patients treated, 205 ; ear patients, 63 ; throat patients, 12 ; total, 280. Number of visits paid by eye patients, 1,341 ; ear patients, 1,020 ; throat patients, 233 ; total visits, 2,594.

THE popular view of the situation at Jefferson Medical College is shown in the following conversation : "Why does not Jefferson bring Dr. I. N. Love, of St. Louis, here to fill Bartholow's place? An able therapeutist, brilliant lecturer, and immensely popular man." "It is not so much brains that are wanted as it is a fat contribution to the Building Fund."

RECEPTION and donation day at the Philadelphia Home for Incurables, 4800 Woodland avenue, occurs Saturday, November 8. Visitors and donations will be received between 11 A. M. and 6 P. M. Gifts in money, dry goods, and groceries are solicited by the managers. In a circular just issued the managers make a special appeal for the cancer annex, and ask that contributions be sent in on donation day.

THE ladies have raised $100,000 as a fund to induce Johns Hopkins to open their medical school to women, and the money has been paid over to the Trustees. The object for which this has been contributed will not be attained until the fund has grown to half a million dollars. There is a shrewd suspicion that other medical colleges would have opened their doors to women for less money ; and have given a course of instruction fully equal to that of Johns Hopkins.

The *National Zeitung* states that Koch is about ready to announce his cure for tuberculosis; which is further said to consist in inoculations which render the body insusceptible to the disease. The introduction of the remedy practically is promised in six weeks; and so important is the matter considered that the government has granted permission to Koch to give up his winter teaching, so that he can devote himself to his (?) new discovery.

A NEW medical journal has appeared. This time it is the *Baltimore Medical and Surgical Record*, a monthly, at $1.00 per annum. The opening number contains forty-two pages of reading matter, mainly from local contributors, among whom are West, Rohè, Jones, and Canfield. There is also a steel plate of Dr. H. P. C. Wilson. The editor is T. H. Graham, who is also proprietor. Baltimore has but one other medical journal, and there may be room for another in that city.

THE primary battery has been applied to the propulsion of invalid chairs in England. A strong chair, weighing about two hundred pounds, is fitted with a battery at the back of the seat, and can be speeded up to about five miles an hour. As it is calculated that the cost of maintenance of the battery does not exceed four cents an hour, and as no renewal would be required during an ordinary day's use, the economy of this mode of propulsion for invalids is apparent.—*Chicago News.*

WHEN the United States removed the duty from coffee, over twenty years ago, Brazil, which supplies nearly all the coffee used in this country, immediately clapped on an export duty. Now, since the McKinley bill has become a law, Brazil has reduced the export duty from 11 to 4 per cent. The price to the consumer has remained the same as it would have been without any change in the duties; the difference being that under free trade the revenue went into the Brazilian treasury, and with the tariff this income is transferred to the treasury of the United States.

A CORRESPONDENT of the Chicago *Tribune* complains that he took a foreign prescription to a druggist in Chicago, who declined to return the paper after putting up the medicine. The writer claims that in England and Scotland the apothecaries return prescriptions, retaining copies. A Chicago druggist thinks that a good case can be made out for both customs, although "under ordinary circumstances, in this city, any druggist will give a customer a copy of the prescription he brings in, unless the physician's request is to the contrary."

A CHINAMAN'S PRESCRIPTION.—The Anniston, Alabama, *Hot Blast* publishes the following as the prescription which a Chinaman handed to a druggist of that city, to be filled for cancer: "Pickled lizards, two pairs; Corea ginseng root, one-half ounce; willow cricket skins, half a dozen; rattlesnake tail, one-fourth ounce; sweet potato vine, one ounce; black

dates, two ounces; red bark, one and one-half ounces; devil-fish suckers, three ounces; reindeer's horn (ground), one-half ounce; bird's claws, one-fourth ounce; lotus leaves, one-half ounce; white nuts, one ounce; dried ginger, one fourth ounce; coffin nails (old ones), five ounces. Boil the whole in two quarts of water, drink two spoonfuls a day, and make paste with the solution and powdered rat's flesh, and apply to the sore."

SECRETARY WINES, of the Illinois State Board of Charities, finds room for much improvement in the Cook county almshouse. The insane hospital has one thousand and eighty-four patients crowded into the space designed to accommodate seven hundred and fifty. Four additional wards are now being erected. Commitments to county asylums are not authorized by Illinois laws, and under these conditions, a patient once committed may be retained for life. Politics ruling the appointment of attendants, their quality is below the mark.

THE managers of the Charity Ball have selected three institutions as beneficiaries for the present season. The Home for Crippled Children, in West Philadelphia, is probably the most deserving of these. There are at present thirty-two of these little sufferers in it, and the institution has only one endowed bed. The Maternity Hospital is simply one department of the University Hospital, which manages in some guise to come in for its share of this charity nearly every year. The Kensington Hospital for Women was started by Dr. Kelly as a private hospital, and since he went to Baltimore has continued under the charge of Dr. Noble.

The Trustees of the Jefferson Medical College postponed until December 8 the election of a Professor of Materia Medica. The vacancy in the College Faculty is to be filled temporarily by an instructor to be selected by the professors. The Trustees received several additional nominations for the vacant Professorship, making the list stand as follows: Dr. Hobart Hare, Professor of Clinical Diseases of Children in the University of Pennsylvania; Dr. Thomas J. Mays, Professor of Experimental Therapeutics at the Polyclinic; Dr. Samuel O. L. Potter, Professor of the Practice of Medicine in the Cooper Medical College, San Francisco; Dr. S. Solis-Cohen, Professor of Clinical Medicine in the Polyclinic; Dr. Daniel E. Hughes, Chief Resident Physician at the Philadelphia Hospital; Dr. Joseph Hearn, a member of the surgical staffs of the Jefferson and Philadelphia Hospitals; Dr. J. S. Alleyne, Professor of Materia Medica in the St. Louis Medical College; Dr. F. P. Henry, a member of the medical staffs of the Jefferson and Philadelphia Hospitals.

ONE of the Louisville journals relates the following incident in the life of Dr. John A. Wyeth. While attending college after the close of the war, he came one snowy day with an old Confederate overcoat on—the only one he then possessed. Some youths prepared to give him a hot reception with snow balls; but, noticing them, he instantly assumed a limp. Nobody would throw a ball at a wounded soldier, and he got inside the gates in safety, when his limp at once vanished, to the great wrath of the boys, who promised him on their next meeting a worse mauling than he had ever received from Uncle Sam's soldiers.

PATENTS, ETC., issued October 28, 1890:—

Cosmetic	A. Bosse	Paris, France.
Electro-dental heater	L. A. Faught	Philadelphia, Pa.
Dental-tool holder	C. M. Richmond	New York, N. Y.
Preparing artificial gums	D. E. Rugg	New York, N. Y.
Dentist's burring-tool	A. W. Browne. (Reissue)	Princes Bay, N. Y.
Apparatus for automatically disinfecting water-closets, etc.	W. & G. Heywood	Middleton, England.
Machine for labeling bottles	S. Cooper	Manchester, N. H.
Obstetrical apparatus	W. S. Hall	Boston, Mass.
Ointment	F. D. Hall	Plattsburg, N. Y.
Operating-chair	H. R. Allen	Indianapolis, Ind.
Decomposing bicarbonate of soda	L. A. Staub	Winnington, England.

CHARLES J. GOOCH, *Patent Attorney.*
LOCK BOX 76, WASHINGTON, D. C.

DONATION DAY to the Philadelphia Polyclinic Hospital, northwest corner of Broad and Lombard streets, on Wednesday, November 12, 1890. The Ladies' Aid Society issues its annual appeal for aid to enable the hospital to carry on successfully its important work. The members of the society will be in attendance at the temporary building, northwest corner of Broad and Lombard streets, on November 12, from 2 to 6 P. M. They will gratefully accept contributions of money for the building fund, or for furnishing the new building, which is to be occupied on or about January 1, 1891. Donations of delicacies for the sick, groceries, provisions, coal, furniture, muslin for bandages or household purposes, cooking utensils, china, glass ware, carpets, rugs and all useful household articles are greatly needed. The expenses of the new building will be great, and this appeal is strongly urged, so as to extend the peculiar usefulness of the

Polyclinic Hospital to a larger number of patients. During the year 1889, 4,607 new patients were treated, and there were 18,006 return visits of old cases, making a total of 22,613 in the twelve special departments. These patients came from twenty-eight counties of Pennsylvania and twelve neighboring States. The work of the hospital for the ten months of 1890 has far exceeded that of any previous year, and the cramped temporary quarters have proven totally inadequate to meet the increasing demands. The new building will afford increased facilities, and its usefulness must depend entirely upon the financial support given it by the public. Its far-reaching charity as the only Post-Graduate Medical College and Hospital in the State of Pennsylvania, carries the appeal for assistance outside the narrow limits of a local charity. Every physician who attends the Polyclinic carries the benefits he has received to the far distant sick poor of his neighborhood, and to the rich as well. Like the Johns Hopkins University, etc., its benefits and its appeal are broad-cast, and it is hoped that similar generous responses may be obtained by the Philadelphia Polyclinic Hospital. It is expected that the new building will be in condition to hold a bazaar on December 3 and 4, so that there will be an opportunity to inspect this thoroughly modern new hospital. Checks should be drawn to the order of Mrs. H. Augustus Wilson, Treasurer to the Ladies' Aid Society of the Polyclinic Hospital; or, Henry Leffmann, Treasurer to the Board of Trustees.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy and Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from October 3, 1890, to October 13, 1890.

By direction of the Secretary of War, the following changes in the stations and duties of officers of the Medical Department are ordered: Major George M. Sternberg, Surgeon, is relieved from duty as Attending Surgeon and Examiner of Recruits at Baltimore, Md., and as a member of the Army Medical Board appointed to meet in New York City, N. Y., and will repair to San Francisco, Cal., and take charge of the Medical Purveying Depot at that place, as Acting Assistant Medical Purveyor, relieving Colonel B. J. D. Irwin, Surgeon. Colonel Irwin, on being thus relieved, will report in person to the commanding general, Department of the Columbia, for assignment to duty as Medical Director of that Department, and as Post Surgeon, Vancouver Barracks, Wash., relieving Major William E. Waters, Surgeon, now Post Surgeon, and temporarily in charge of the Medical Director's office. Major Waters, on being thus relieved, will report in person to the commanding officer, Fort Custer, Mont., for duty at that station. Par. 8, S. O. 232, A. G. O., October 3, 1890.

By direction of the Secretary of War, Major Van Buren Hubbard, Surgeon, is relieved from duty at Columbus Barracks, Ohio, and will report in person to the commanding officer, Fort Spokane, Wash., for duty at that station, relieving Captain Henry S. Turrill, Assistant-Surgeon. Captain Turrill, on being relieved by Major Hubbard, will report in person to the commanding officer, Madison Barracks, New York, for duty at that station, relieving Major John D. Hall, Surgeon. Major Hall, on being relieved by Captain Turrill, will report in person to the commanding officer, Fort Canby, Wash., for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Captain Rudolph G. Ebert, Assistant-Surgeon, is relieved from duty at Angel Island, Cal., to take effect upon the arrival at that post of Major William H. Gardner, Surgeon, and will then proceed to Vancouver Barracks, Wash., and report to the commanding officer of that post for duty. S. O. 232, par. 15, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Captain Robert B. Benham, Assistant-Surgeon, will proceed from Fort Hamilton, New York, to Mount Vernon Barracks, Ala., and report in person to the commanding officer of that post for temporary duty, relieving Captain John J. Cochran, Assistant-Surgeon, who will return to his proper station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Captain C. N. Berkeley Macauley, Assistant-Surgeon, is relieved from duty at Fort Supply, Indian Territory, and will report in person to the commanding officer, Fort Lewis, Colo., for duty at that station. S. O. 233, par. 2, A. G. O., Washington, D. C., October 4, 1890.

By direction of the Secretary of War, leave of absence for three months is granted Captain Robert J. Gibson, Assistant-Surgeon, to take effect on being relieved from duty at Fort Trumbull, Conn., by Major Henry M. Cronkhite, Surgeon. Par. 12, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Captain Arthur W. Taylor, Assistant-Surgeon, is relieved from duty at Fort Wingate, New Mexico, to take effect on the expiration of his present sick-leave of absence, and will report in person to the commanding officer, Fort Adams, Rhode Island, for duty at that station, relieving Captain J. J. Cochran, Assistant-Surgeon. Captain Cochran, on being relieved by Captain Taylor, will report in person to the commanding officer, Camp Eagle Pass, Texas, for duty at that station, relieving First Lieutenant Paul Clendenin, Assistant-Surgeon. Lieutenant Clendenin, on being relieved by Captain Cochran, will report in person to the commanding officer, Fort Brady, Mich., for duty at that station. Par. 8, S. O. 232, A. G. O., Washington, D. C., October 3, 1890.

By direction of the Secretary of War, Captain Walter Reed, Assistant-Surgeon, is relieved from further duty at Mount Vernon Barracks, Ala., and assigned to duty as Attending Surgeon and Examiner of recruits at Baltimore, Md. Par. 7, S. O. 233, A. G. O., Washington, D. C., October 4, 1890.

Leave of absence for one month, on surgeon's certificate of disability, is granted Assistant-Surgeon, N. S. Jarvis. S. O. 107, Dept. of Arizona, October 14, 1890.

By direction of the Acting Secretary of War, the retirement from active service, on October 12, 1890, by operation of law, of Captain Andrew V. Cherbonnier, Medical Storekeeper, under the provision of the act of Congress, approved June 30, 1882, is announced. Par. 11, S. O. 240, A. G. O., Washington, D. C., October 13, 1890.

By direction of the Secretary of War, leave of absence for four months is granted Captain J. E. Pilcher, Assistant-Surgeon. Par. 12, S. O. 244, A. G. O., October 18, 1890.

By direction of the Acting Secretary of War, the retirement from active service on October 12, 1890, by operation of law, of Captain Andrew F. Cherbonnier, Medical Storekeeper, under the provisions of the Act of Congress approved June 30, 1882, is announced. Par. 11, S. O. 240, A. G. O., Washington, D. C., October 13, 1890.

PROMOTIONS.

IRWIN, BERNARD, J. D., Lieutenant-Colonel and Assistant Medical Purveyor. To be Surgeon, with the rank of Colonel. August 28, 1890.

FRYER, BLENCOWE E., Major and Surgeon. To be Assistant Medical Purveyor, with the rank of Lieutenant-Colonel. August 28, 1890.

COWDREY, STEVENS G., Captain and Assistant-Surgeon. To be Surgeon, with the rank of Major. August 28, 1890.

APPOINTMENT.

VOLLUM, EDWARD P., Colonel and Surgeon. To be Chief Medical Purveyor, with the rank of Colonel. August 28, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending October 25, 1890.

CERDEIRO, F. J. B., Past Assistant-Surgeon, detached from U. S. S. "Nipsic" and granted three months' leave of absence.

HEFFINGER, A. C., Past Assistant-Surgeon, placed on the retired list, October 20, 1890.

The Times and Register.

THE PSYCHOPATHIC SEQUENCES OF HEREDITARY ALCOHOLIC ENTAILMENT.[1]

By C. H. HUGHES, M.D.,
ST. LOUIS,
Professor of Psychiatry and Neurology, Marion Sims College of Medicine, Late Superintendent of the Missouri State Lunatic Asylum No. 1, etc.

NOTHING in neuropathology is now plainer than the retrograde heredity of chronic alcoholics. The alcoholic poison interferes with the highly organized physiological movements of the psychical centers, arrests and perverts the complex activities of the cerebral cortex, and begins a decadent and perverted neural metamorphosis that goes on from one stage of instability to another, until the final ending of all neural instability is reached (unless fortuitously arrested) in dementia or imbecility and death, when even perverted neural force can no longer be evolved. The evolution of the cerebro psychical centers thus arrested or perverted, ends in final dissolution and extinction of type.

The neuropathic thrall of entailed alcoholism is no new theme to neurologists. It was familiar to Benjamin Rush, and the researches of Morel in the field of neuropathic degeneracy sequent to ancestral alcoholic excess, have been so often affirmed and reaffirmed by credible medical testimony that no doubt now remains, in the medical mind, of the power of excessive ancestral alcoholic indulgence to pervert neuropsychic function in the descendants of the victims of this vicious disease.

We need not dispute the point as to whether alcoholism is a vice or disease, for it is, and it may be both or either, and whether it in the beginning be one or both its ending is always in disease, which is either the beginning or continuance of a transmitted neuropathic or neuro-psychopathic heritage.

If the first generation, as Morel has observed, shows immorality, alcoholic excess and brutal degradation, the second one will usually show, as he also observed, hereditary drunkenness, maniacal attacks, and general paralysis, or some similar psychopathic affection. The third generation may show sobriety, but instead of the transmitted drunkenness, the hereditary neuropathic perversion will probably reveal itself, as Morel saw it, in hypochondria, mania, lypemania and tendency to homicide and suicide; and we shall see in the fourth and after-coming generations feeble intelligence, stupidity, early insanity and the beginning of the end of the family in extinction.

All alienists have confirmed this observation of Morel, and the fatal heritage of chronic alcoholic toxhæmia is proven upon those living within the walls of asylums for the insane the world over, and in every walk of life without, and upon the cadavers of those who have died under the power of this neuro-toxic force. We no longer need the extensive clinical observations of Magnan nor the later pathological researches of Bevan Lewis for proof. The diseased arterioles, the granular degenerations of the nerve cells, pericellular and perivascular nuclei proliferation, aneurismal dilatations and exudative and indurative cerebral changes, are too familiar now to be longer doubted, and witnesses too many to be here enumerated, embracing all who have clinically studied inebriety, attest the fact that the habitual long-con-

[1] Read before the Mississippi Valley Medical Association, at Louisville, Ky., October 9, 1890.

tinued use of alcohol as a beverage in excessive quantity in one generation makes an indelible impress upon the nerve stability of the generations that follow.

It has the undoubted power of engendering neuropathic and psychopathic conditions *directly* in the individual, besides a great number of extra neural morbid conditions, as the oft observed and no longer doubted delirium tremens, epilepsy, insanity and imbecility, paralysis and the neuritides of drunkards show, and the morbid entailments of alcoholic excess do not stop with the individual as we have seen. They pass over in greater force to his descendants. This is the gospel of science. These morbid endowments of the drink habit are more apparent in the drunkard's progeny, for the reason that his children come into the world dowered with less power of neurotic resistance to the depressing and perverting assaults of alcohol and its compounds upon the integrity of the ganglion cells of the cerebrum and the nervous centers of the whole cerebro-spinal axis and sympathetic system.

By reason of a better organic heritage and the greater inherent power of vital resistance, the drinking person may show but little of the inroads his alcoholic excesses are making upon the physiological soundness of his cerebro-spinal and ganglionic centers. An occasional or single epileptic seizure during a debauch, or none at all, during a life given to drink; some perversions of disposition or mental depression, or a day or two of trance following a prolonged spree once or twice in a life-time, or none of these evidences of cerebro-psychical damage may so markedly appear. (The subject of alcoholic trance is too extensive to be treated here as its forensic merits require. We content ourself now with a simple note. *Vide finis.*)

None of these positive and more directly perceptible consequences of alcoholic damage may appear directly in the individual. He may go through life moderately full of alcohol, able to attend in a fairly good manner to the routine demands of his business, to be cut off prematurely under some slight extra organic strain (for one of his extraordinary hereditary endowment of nerve resistance), by an apoplexy —cerebral or pulmonary—or hepatic disease, which another less strongly endowed for resistance by nature, would have withstood. His ganglionic centers fail him in some vital crisis, and the "silver cord is loosed" forever.

The nerve mechanism, which never escapes in the habitual or periodic excessive drinker, but more especially in the regular so called moderate social drinker (who never sprees, though seldom refuses when asked to drink, who takes his regular evening night-cap, and morning eye-opener, and tri-daily appetizer) is the vasomotor system. This failure causes the pneumoniac to die from an attack of lung fever of no greater severity of causation than that of which his non-drinking fellow in the next bed promptly recovers. He may die prematurely of an over-worked kidney or an over-taxed liver, by reason of ganglionac paralysis (and I believe that over distension of the renal circulation from the general vascular hyperæmia of over-brain strain and alcoholic stimulation combined, are the remote causative factors of Bright's disease), and neither he nor his friends may think that alcohol has done him harm.

But look at the drinking man's children! He may have been himself a very proper and apparently healthy citizen, beginning in early life a regular business, and having acquired and filled a regular and honorable business place in the world, and never seriously sick till the last acute illness that suddenly carries him off before his physiologically appointed time.

Why is one child an idiot or imbecile, another erratic, moody, violent, visionary, melancholic, or insane, epileptic, choreic, or suddenly criminal despite the best of training and environment, especially among his latest offspring, while only the children born of his loins earlier in life, when alcoholic excess had made no organic impress upon him, are ordinarily healthy in mind and body?

The habitual disturbances of organic functions—morbid physiological exaltation, and reactionary morbid depression, through increased vascular relaxation and consequent capillary congestion, may not materially affect the integrity of function in the matured cells of the psychical centers of the parent of sober lineage, so as to markedly modify their matured and long-established habit of acting, but in the drunkard's child, who starts unstably endowed by hereditary neuropathic entailment resulting from an ancestor's alcoholic excess, the resistance power of the parent or parents in early life is not in the child's organism. He is a step lower than his father or mother, or both, if they were habitual drinkers, in the scale of organic degradation, and has, in consequence, feeble resistance to the assaults, not only of alcohol from within, but of adverse environments from without, and they reveal this hereditary organic degradation in erratic actions, morbid, insane or criminal conduct—conduct which in them is always the offspring in whole or in part, of disease—disease within. Upon them, consequently, influences without their organisms, resisted by others, have an overpowering force. Their environment leads them irresistibly into crime, like the extraneous circumstances which cause in them disease their parents had not shown, and crime their parents would have resisted.

The drunkard's child's crime is not all his voluntary crime, nor his vice engendered disease, all disease of his own making. His father, or his father's father or mother, may have deliberately chosen that which, with all its voluntary seeming in the boy, is become to him an inexorable morbid fate, appearing as immoral conduct. "The fathers have eaten sour grapes, and the children's teeth are set on edge."

With this too cursory preliminary review of what we know of the hereditary neurotic enthrallment of alcohol, we record an interesting hypothetical case, which we will suppose to cover the facts in an important medico legal record of entailed alcoholic disease and crime perpetrated under its fatal sway.

HYPOTHETICAL CASE.

Suppose a young man approaching his majority, naturally kind of heart, not reared in crime nor in the slums of a city's poverty quarters, but in comfortable circumstances, and fairly educated among correct people, commits an unprovoked murder of one of the dearest and nearest of his friends. In his family the following abnormal traits appear: On the maternal side a grandfather is a man of excess in eating, drinking, etc.; inebriate and melancholy, and he dies of apoplexy. An only son survives him long enough to develop inebriety and die of drink in his youth. A brother is like himself, and dies a drunkard. Sisters and cousins in varying degrees, according to environment, exhibit the same failing. A grandmother at an early age drank liquor to excess, and died prematurely in consequence of excessive drink. All the sons of the grandmother's sisters died young in consequence of drink. Of the remaining ancestry of this alcohol-tainted organism, one uncle was, from early youth, addicted to alcoholic indulgence, his thirst for drink becoming finally insatiable, and he died of delirium tremens in early manhood, after previous attacks of acute alcoholic insanity. An-

other uncle was also addicted, from his early youth, to the use of alcohol to inebriety, and finally became melancholic and insane with delusions of dread and suspicion. Several sisters of these two men were victims of the hereditary failing, among them the mother of the supposed young man we are considering. The boy's father, too, was in early life, before the boy's birth, an intemperate man, and the boy himself was, from early puberty, intemperate, unstable and choreic, and had suffered in childhood from a physical shock to his nervous system, caused by a violent fall. This young man in question, when under the influence of liquor, was a markedly changed man, and when the time of one of his periodically recurring sprees would come around, he was likewise very different from his natural self, being moody, listless, drowsy and melancholy; and after indulging in his inordinate craving and unnatural appetite, he would become exhilirated, reckless of danger, excessively cheerful at times, and extremely violent towards, and suspicious of his best friend, filled with morbid fears, dreads and suspicions. When sober he was nervous, restless and unhappy, and whenever he got a taste of liquor he would invariably drink to excess—drinking to exhaustion, prostration and illness in consequence of his excess. Suppose for five or ten years the life of such a person was almost one continual succession of sprees—suppose such a man, after such a life, and at the close of a several weeks' prolonged spree, takes the life of his best friend by manual violence while struggling to get money from this friend who had refused it, and with the aid of an accomplice takes money, jewelry and other valuables from his person, pawns some of the things for liquor, making no attempt to escape, and not appearing to remember or realize the enormity of the crime committed, remains in the neighborhood of the murder intoxicated until arrested, vaguely remembering the fact of the robbery, but not believing the party robbed and maltreated was dead or seriously injured.

This is a common kind of inebriate crime. This picture would answer for the ordinary portraiture of the average inebriate criminal arraigned in our courts of justice. It is of necessity so drawn as not to describe personal cases that have come under my professional care, but it is true to inebriate nature, as I have seen it all too pitiably and painfully portrayed, and will answer well for a composite picture of morbid, as contradistinguished from purely immoral inebriety and crime. The picture is not overdrawn, but is faithfully true to nature.

I have purposely put in a criminal motive in the above hypothesis that the natural semblance to crime may appear just as it appears in many cases of insanity. The inebriate and the insane person act, unless totally demented, from motive more or less apparent, but the hidden springs of human conduct in both are different from those in the rational and healthy mind. A different combination of morbid influences, ancestral and immediate, in the nervous organism of the chronic inebriate or the periodic inebriate, unites with his environment in the drink-enthralled man, from that which influences and determines ordinary human conduct in sane and temperate men.

1. Assuming the above hypothetical case to be true, what would be your judgment as to the existence or non-existence of hereditary alcoholic degeneracy and impairment of the brain, and the existence or non-existence of dipsomania, or involuntary and resistless impulse to drink alcoholic liquors to excess, in the case of the supposed youth, and degree of irresponsibility from drink?

2. What was the mental condition of the supposed person when he committed this unlawful deed?

3. What is the effect on the mind and on the will of such an inherited taint, united with the state of chronic alcoholism, as in the case of such a supposed youth?

Such, with more or less completeness of specific detail, is the character of the hypothetical case and interrogatories of late years propounded in our courts to the expert in psychiatry, for the neuropathic entailments of chronic ancestral alcoholism. Thanks to an enlightened judiciary in some of the American States, aided by the wise and judicious efforts of our medico-legal societies, inebriety has become a recognized extenuation and often complete and just excuse for crime perpetrated under its potent and often resistless morbid influence, and the following, or something like them, are still the customary interrogatories propounded, *pro forma*, by the counsel for the State:

1. Is it your opinion that such a supposed person was unable to distinguish between right and wrong?

Or, perchance, the more enlightened and just interrogatory, like the following, is offered by the State:

"Will you say that a person so affected could not tell that an act which he committed was wrong, or, if conscious, that it was wrong—is it your opinion *that he was incapable of resisting the impulse to commit it*, by reason of disease hereditarily entailed or acquired?"

It were fortunate for the unfortunate victim of the faulty and imperiously unstable neuropathic heritage of long-continued or hereditarily transmitted alcoholic indulgence, if a wise, humane and considerate counsel and court secure such just instructions in such clear conformity with the facts of clinical observation and experience as the last interrogatory would warrant, for inebriety either in its periodic or continuous forms is a disease, as much so as the recognized and acknowledged phases of insanity, epilepsy, idiocy and imbecility it both directly and indirectly engenders, and while in considering it in its medico-legal relations, we have also to consider the accompanying factor of a once normal volition, we have in the inebriate a mind and will always more or less modified, perverted, or deranged by disease; alcohol being itself a directly toxic agent, in its influence on the brain and allied nervous system, as well as potently poisonous to the blood itself in any considerable quantity, and especially so as all experience proves, when long continued, in excess, in either the individual or his ancestors.

It is, indeed, a strange phenomenon of the human mind in its forensic relations that an agent which the world recognizes and acknowledges as the parent of pauperism, insanity and crime, and the chief direct or indirect populator of penal, eleemosynary and correctional institutions, and the proven cause of so much disease, misery and death, should be held responsible to the extent it is before our judicial tribunals, when the hapless and often hopeless and helpless victims of its vicious power are arraigned to answer for crime committed through its influence over their involuntarily enslaved organisms—organisms often prenatally predestined to pathological perversion (as most of the unfortunate inmates of asylums for the insane are organically predetermined to an aberrant course of life conduct), through the alcoholic excesses or other neuropathic disorders of ancestors, or through a precocious drink-craving, however engendered, whether ancestrally or self-acquired, and prematurely and excessively indulged, to the harm of the delicate machinery of the brain.

The force of physiological habit is recognized in all of our dealings with men. Why, then, should courts

ignore the power of that neuropathic thralldom which alcohol undoubtedly engenders in certain individuals, to their harm and the harm of the world about them, enchaining, enslaving and perverting conduct, until the unfortunate slave of its vicious sway is no more in harmony with his natural self, unperverted by this disease, than the lawfully and justly consigned inmate of a lunatic asylum is?

The dipsomaniac is as surely perverted and deranged in his brain and connected nervous system as any other lunatic, and the confirmed inebriate claims our sympathy and succor and the kindly consideration of the law, because he is the victim of disease. It is for humanity and the law to decide in each individual instance, however, how far on the one hand inebriety should extenuate crime, and to what extent on the other it should punish the volition that may have engendered the disease. It is a plain proposition, which admits of no doubtful interpretation, that acute alcoholism voluntarily and premeditatively induced, or even voluntarily yielded to, for the purpose of committing or shielding from crime, is as culpable as any other criminal intent, while on the other hand a diseased propensity to drink, indulged in obedience to the promptings of a resistless organic aptitude handed down from father to son, or transmitted through the womb of an alcoholized or otherwise neuropathic mother, should receive a different consideration, just as any other neuropathic heritage causing psychopathic perversion, extenuates even the most heinous of crimes in the eye of the law and in the judgment of courts.

Our ancestors in the medical profession rescued the lunatic from the neglect and violence of ignorance: let us protect and save the nerve-degenerate inebriate.

NOTE.—A correspondent of the *Courrier des Etats-Unis* sends from Paris, under date of September 20, 1890, the following mention of a recent trial for homicide, committed in that city under somewhat peculiar circums ances, and of the prompt acquittal of the accused on the ground of mental irresponsibility. We present to our readers a translation:

On April 20 last, at 11 o'clock A.M., a cry for help was suddenly heard to proceed from a house in Park Royal street, an apartment of which was occupied by a widow, aged twenty-seven years, named Bohringer. The neighbors met a man on the threshold of her room who remarked: "You can enter. It is all over with her. There she is,"—at the same time pointing to the young woman, who lay stretched on the floor in a pool of blood. The victim had been struck with a finely-sharpened cold-chisel. After being conveyed to the Hospital St. Louis, she was able to speak but a few intelligible words, and died after an agony of a few days.

The assassin, named Joseph Hahn, a widower and the father of three children, had long paid assiduous court to the deceased, with the expectation of marriage. That he had premeditated the crime was patent from the fact that he had hired a cutler to sharpen the chisel, the day before. It was satisfactorily shown before the court that Hahn was a skillful workman, that his probity was incontestable, that he adored his children, but that, when drinking, he became violent and brutal, destroying or injuring whatever was within reach.

At first sight, the tranquil face of Hahn in no way betokens insanity; but his attitude before the court and the audience was so singular as properly to raise a doubt in this regard.

The following were his replies to questions by the court:

Court. The police report represents you to be an honest man.

Hahn. Yes; I have always been honest. I have never in my life intentionally done harm to any one. But sometimes I drink too much, and then it affects my head, so that I know no longer what I do.

C. Why do you drink?

H. Because I am obliged to associate with the public in order to procure work.

C. You met the Bohringer woman in a Roquette street restaurant. Did you know that she had a lover?

H. No; I did not know it.

C. Did you propose marriage to her?

H. No; it was she who proposed it to me. We were to be married at the end of her term of mourning. We had but two months more to wait.

C. Then why did you kill her?

To this question Hahn at first replied: "I do not know;" and then, gesticulating wildly, he said, amid loud sobs: "I loved that woman as I did my eyes. She deceived me. She had an accepted lover, and I did not know it. She gave me by mistake a handkerchief belonging to that lover. She had consumed my money."

Doctor Ball testified to the limited responsibility of the prisoner. "Hahn," he said, "occupies the very borderland of insanity; he is of so hysterical a temperament that he does not enjoy the full possession of his faculties."

The jury rendered a verdict of acquittal. On the reading of the verdict Hahn appeared astounded and stupefied for several minutes.

WIRING THE SEPARATED SYMPHYSIS PUBIS, SUPPLEMENTED BY A NOVEL PELVIC CLAMP.

By WILLIS P. KING, M.D.,
KANSAS CITY, MO.

I WOULD not deem it necessary under any circumstances to tire the patience of a body of physicians by going over the entire question of fractures of the pelvis, as an introduction to a paper of this character, and I deem it especially unnecessary before a body of men such as compose this association. I will, therefore, be as brief as possible by coming at once to the point. The object of the paper is to report a case of separation of the symphysis pubis, with fracture of the interposed fibro-cartilages, fracture of the descending ramus of the pubis, with deep lacerations of the surrounding soft parts, and, more particularly, to report the methods resorted to in order to support the pelvis and reinforce the sutures after the pubis had been wired together.

Bonnie Jacobs, aged twenty, single, a hearty, well-developed country boy, brakeman on a freight train on the Missouri Pacific Railway, while making a coupling at Harrisonville, Mo., on March 25, 1890, fell down with one leg under a brake beam, and the other over it, holding on to some part of the car with his hands, and was shoved about one car length, the brake beam crushing into the anterior portion of the pelvis, fracturing the descending ramus of the pubis, separating the symphysis, and lacerating the surrounding soft parts, as hereafter described.

He was received at the Missouri Pacific Hospital at Kansas City during the night following, and, as it was found upon examination that there was no hemorrhage, the parts were cleansed and packed with bichloride gauze, his urine drawn off, and he was put to bed until morning. On the morning of the 26th, he was placed upon the operating table and anæsthetized, and a careful examination made. The pubic symphysis was found to be separated about two inches, the inter articular fibro-cartilages were each broken into three or four pieces, the descending ramus of the pubis on the right side was fractured; the inner border of the adductor longus muscle was lacerated, and there were extensive lacerations of the soft parts above the pubic arch, exposing the bladder and extending on the right side into the right inguinal region. These deep lacerations above the pubis embraced the skin and all of the underlying muscles and tissues in the supra-pubic region down to the bladder, and extending upward to the right and left; but the lacerations on the right side extended somewhat higher up than those on the left. The fragments of the fractured cartilages were removed, and the centers of the opposing surfaces of the separated pubic arch were roughened with a chisel—the edges being

[1] Read before the Mississippi Valley Medical Association.

already roughened in the separation; then with a common drill and a small dental tool two holes were drilled in each side. These holes began about three-fourths of an inch back from the edge on either side, and the tool was permitted to emerge just above the inferior surface of the bone. A strong silver wire (the largest made) was then passed through each of these, and while an assistant pushed upon the pelvis from each side, until there was coaptation of the separated symphysis, the wires were twisted down, cut off short, the ends turned down and hammered in between the ends of the bones.

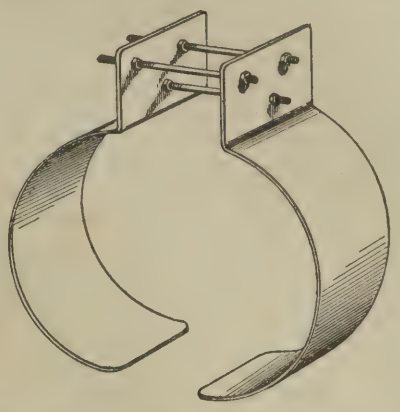
The bladder, having filled with urine during this operation, was emptied, and the deeper lacerated tissues were whipped, quilted and stitched over it with cat-gut. The irregularly torn integument was then drawn into position and closed with silk. Rubber drainage tubes were put in at appropriate points, so as to thoroughly drain the whole injured region.

Feeling assured that the two silver wire sutures in the pubic arch would not be sufficient to hold the symphysis together, the patient was then lifted on to blocks—the blocks being under the upper part of the thighs and lower part of the spine, a half-gallon rubber water bag was filled with water and laid over the pubis—covering the entire wounded surface. Two thicknesses of flannel were then thrown around the pelvis, covering about eight inches in width and passing over the water bag. Over this, plaster of Paris in crinoline was passed, and two perforated barrel hoops were worked in between the layers of plaster. The plaster was put on quite thick, so that there would be no spring in it after it set. After the plaster had hardened, the stopper was taken from the water bag, and the water emptied into a vessel between his thighs, and the collapsed bag removed. This left an ample arch under which to apply the dressings to the wounded parts.

This plaster support was kept on for twelve days; but, as he was delirious and the contents of his bowels moved involuntarily, the back part of the cast became so foul as to necessitate its removal. It was then cut away, and a drawing of a pelvic clamp was hastily made and sent to the company's shops. In the meantime a broad, strong bandage was applied around the hips, extending over the dressings. On the same evening the clamp was received and applied. This clamp was of steel plate, one-eighth of an inch in thickness, and was in two parts—each being fashioned after the plaster of Paris cast, which had been sent to the shops. Each part extended over the curve of the hip so that it would not slip up when tightened. The lower part rested on the bed, but did not extend under the body. Each part embraced the pelvis on its side, curved up and over to the iliac fossa, and then turned to a right angle upward. The flat surface of this part faced a similar flat surface on the opposite side, and when applied without being tightened were about five inches apart. Through these surfaces three holes were made in the form of a triangle, and bolts, with screws, cut on each end, passed through. The three bolts were necessary, because I knew that, with one or two bolts, the clamp would rock and would, therefore, not serve the purpose for which it was made. Taps were put both on the inner and outer side. The reason for this is obvious.

The hips being neatly padded, the clamp was applied, and the screws being tightened, it was found to be not only an excellent support, but that we could apply as much or as little pressure as was desirable. The supra-pubic wound (which had not all healed by the first intention) was dressed beneath the connecting rods.

This pelvic clamp was kept on until the thirtieth day after the injury, when, as it appeared that there were perfect union of the symphysis, it was removed.



The patient was delirious for twenty-eight days. He urinated in the dressings, necessitating a change of the dressings two and three times in twenty-four hours. Of course we had suppuration; but, as our drainage was perfect and permitted a thorough irrigation of the wounds, we were enabled to prevent the burrowing of pus, as well as to prevent the spread of septic material in the surrounding soft parts. For the first thirty days he had more or less temperature—the fever at one time rising to 105° Fah.

He was kept on a water bed from about the end of the first week until he was able to leave his bed as a convalescent. There was suppuration at the point of fracture of right descending ramus of pubis, and where a portion of the adductor longus muscles was lacerated; for a long time pieces of detached necrosed bone coming away at times. He left his bed for an invalid chair at the end of about five months. Within three weeks after this he began to use crutches, and ten days afterward he threw his crutches away and used only a cane. Now (for the last two weeks) he is walking up and down stairs—everywhere—without any support. He is growing strong rapidly, and, I feel assured, will in a short time be ready for any duty.

Drs. F. R. Smiley and Geo. F. Hamel, my house-surgeons, assisted in the operation of wiring, and Dr. Hamel took personal charge of the case, and the good result is due largely to his indefatigable and unwearying attentions at all times, day or night, when the patient's condition demanded it.

The case suggests some valuable points:

1. The operation of wiring in a case of separation of the pubic symphysis so completely coaptates the parts that it would seem that scarcely any other method of dealing with this condition can be equal to it.

2. The manner of applying the plaster of Paris support in the first place, with the use of the water bag to make an arch under which to dress the wounded parts, is new and original, so far as I know, and is a method that may be adopted and easily practised by any one who knows how to use plaster of Paris.

3. The steel hip clamp as a permanent support in separation of the pubic symphysis is also new, so far as I know, and is a means that may be adopted with benefit in any case of fracture of the pelvis, where immobilization of the fractured part will contribute to the comfort of the patient, and to the union of the fracture.

DR. R. J. LEVIS died, November 12, of pneumonia.

TREATMENT OF EPILEPSY.[1]

By PHILIP ZENNER, A.M., M.D.,
CINCINNATI.
Clinical Lecturer on Diseases of the Nervous System in the Medical College of Ohio.

IN order to judge properly the effects of remedies on epilepsy it is necessary to study the natural course of the disease, and how other influences than therapeutic measures modify the disease.

According to Nothnagel 4 to 5 per cent. of the cases of epilepsy get well without treatment. Various pathological processes may favorably modify the disease. Acute febrile processes sometimes cure it, and, generally, cause a temporary improvement. Injuries and wounds, or surgical operations are likely to be followed by lessened frequency, or a longer or shorter absence of the fits. A change of scene or place, entering an asylum or hospital, or the administration of a new drug, are likely to cause temporary improvement.

The success of therapeutic measures depends largely on the form of disease presented. *Grand mal* is much more amenable to treatment than *petit mal*. The latter, and cases with mental symptoms, are usually very intractable to treatment. The shorter the duration of the disease, and the smaller the number of attacks, the more favorable is the case for treatment.

The etiological factors are exceedingly important in relation to treatment. In all cases there is a constitutional vice, either hereditary or acquired, without which the disease would not exist. Besides this there is, in many cases, a peripheral source of irritation which, in a reflex way, excites the attack, and may even have produced the constitutional condition. Among such conditions may be mentioned injuries and wounds, disturbances in the digestive tracts, various genito-urinary diseases, eye strain, disease of the nasal mucous membrane, etc. Very often too much weight has been given to such conditions, and even harm done in their treatment, but we must also be careful lest we run into the other extreme, and give them no weight. Each case must be individualized and carefully treated on its own merits. But in all cases, whether such local disease be found or not, treatment for the constitutional condition should be applied, chiefly proper hygiene and hyrotherapy.

With this treatment we may succeed in many cases without further medication, especially when there have only been a few convulsions. But in the chronic cases we must add some of the anti-epileptic drugs. The number of such drugs which have been handed down to us is very large. The most important of those of the pre-bromide period are nitrate of silver, oxide of zinc, digitalis, and belladonna. Of these belladonna is the most used to-day, and is often a valuable adjuvant to the bromide treatment. Digitalis is more or less in use, being of greatest value in cases with weak hearts and feeble circulation. But the bromide treatment has supplanted all others to-day, and is far more effective in the majority of cases. As to the size of the dose there is great variability, some not bearing small doses well, while others can take four or five drachms daily for an indefinite period. There is but one rule to follow, to give large enough doses either to entirely control the disease, or to produce slight bromism. It is best to begin with small doses, one drachm two or three times a day, and gradually increase until the desired effect is obtained. Sometimes the medicine seems to lose its effects with time; then an increase is necessary. After learning what dose can be borne, or is effective, the medicine should usually be continued in same doses for a long time. When the convulsions only occur at stated periods, as during the menses, it is well to give large doses for a few days before the attack is expected, and in the interval give smaller doses. If no more convulsions appear, two or three years should be allowed to elapse since the last fit before beginning to gradually reduce the medicine. If the convulsions recur at times it may be necessary to continue the medicine for life.

The medicine should not be discontinued suddenly, unless for urgent causes, as such a withdrawal may be followed by severe recurrence of the disease. If it be necessary to reduce the drug for other reason than its long control of the disease, it is best to substitute the deficiency with some other anti epileptic drug. Seguin speaks very highly of chloral used for this purpose. He often substitutes from one fifth to one-half of the bromide dose with an equal quantity of chloral, and thinks the combination has a greater control of the fits, and less ill effects, than the larger doses of bromide.

The ill effects of the long-continued use of the bromides can often be averted with care. The disturbances in the digestive tract can often be avoided by very largely diluting the drug, preferably in alkaline waters. Cutaneous eruptions need usually not interfere with the treatment. Sometimes they can be controlled with arsenic. The blunt condition of will and intellect is often less noticeable after the system becomes accustomed to the bromide, or can be improved by slightly diminishing the dose. The same is true of the altered disposition, irritability, etc., sometimes manifested after the fits have ceased to appear. Any tendency to impaired nutrition may, perhaps, be avoided by administration of cod liver oil tonics and nutritious food, and a weak heart may be supported by digitalis.

If great attention is paid to details and the patient can be persuaded to persevere in the treatment—always a difficult matter—most cases can be benefited, and in quite a number a practical cure, and in a few an actual cure can be effected.

The bromide of potassium is the kind of bromide in most common use, and is very effective, but on account of its having a less depressing effect on the heart the sodium salt is often preferred. A mixture of the bromides of potassium, sodium, and ammonium is a favorite combination.

Other bromide preparations, bromide of gold, of nickel, etc., have, as yet, had no extensive trial.

A number of other drugs have appeared in the medical journals in the last year or two in connection with the treatment of epilepsy. Borax, though not a new drug, has been tried at many hands, in some instances with favorable effects, in others unsuccessfully. It is given in from ten to thirty grain doses. After long use it is liable to produce ill effects, as disorder of the alimentary tract, cutaneous eruptions, impaired nutrition, etc., which may be averted to some extent by largely diluting the drug, arsenic, cod liver oil, etc. The author tried it in a number of cases with apparently favorable effects, but the time is yet too short to tell any thing of its real value.

Amylhydrat was found very valuable in the status epilepticus. Antipyrine, antifebrine, and some other drugs recently used seem to have a temporary but not a permanent control over the fits. Probably many of these remedies will assist us where a temporary

[1] An abstract of a paper read before the Mississippi Valley Medical Association at Louisville, Kentucky, October 10, 1890.

suspension of the bromides is necessary, and perhaps they may prove to be of value in combination with the bromides. Amadel states that for four months no convulsions occurred in the asylum at Cremona since he combined the antipyrine with the bromides.

Surgical Treatment: Operative procedures which have been long cast aside, and ligature of the vertebral arteries whose value is, at least, doubtful, were brought into review.

Trephining for epilepsy is one of the oldest operations of surgery. At one time it was resorted to in any or all intractable cases. Thus brought into discredit for a long time it was scarcely done at all. To-day it is done with more discrimination.

It is now resorted to chiefly in traumatic cases. The success denoted by statistical tables is misleading. Most reports are made within a short time after the operation, whereas a number of years should be allowed to elapse before a cure is pronounced.

The author believes those cases to be appropriate for an operation in which the lesion is a limited one, its location ascertainable, and its removal possible; that is, the operation must have a distinct and definite purpose, the removal if a source of irritation. The location of the lesion should be indicated by either local symptoms, such as local pain or tenderness, reflex phenomena, convulsive movements, or fully developed convulsions produced by pressure over the source of irritation, etc., or nervous (cortical) symptoms such as monaspasm (Jacksonian epilepsy), monoplegia, aphasia or sensory, ocular, aural symptoms, etc.

The object of the operation should be the removal of the source of irritation, the extirpation of the entire area of the disease. In order to do this it may be necessary to remove, in connection with the cicatrix, surrounding brain substance.

Those cases are more favorable for a complete cure where the epilepsy is of the Jacksonian type, because it is more likely that the lesion is quite circumscribed, and that with its removal the disease will be eradicated. When the epilepsy is of the ordinary type there is the probability that the disease has been fully engrafted in the system and will not disappear with the removal of original source of irritation. For similar reasons there is a greater probability of success if the operation is performed soon after the injury than if performed at a later period.

Operations have also been made in a small number of non-traumatic cases where the disease was of the Jacksonian character. The idea is to remove the cortical center wherein the disease appears to be located. It is yet too early to say whether this operation will have a future.

SPONTANEOUS (NON-INSTRUMENTAL) ACCESS OF BACTERIA TO THE BLADDER

AND SLIGHT VESICAL INCOMPETENCE AS CAUSES OF CYSTITIS, ESPECIALLY IN THE FEMALE, WITH REMARKS ON TREATMENT OF THE RESULTING DISEASE.[1]

By R. VAN SANTVOORD, M.D.
NEW YORK CITY.

THE writer reviewed the literature of spontaneous bacteriuria, *i. e.*, of cases in which, in the absence of specific disease, bacteria for the most part indistinguishable by ordinary microscopic examination from those usually found in decomposing urine were present in freely passed urine. Stress was laid especially on a paper read by Dr. Wm. Roberts before the International Medical Congress in 1881, in which he distinguished between two forms of spontaneous bacteriuria, in one of which the urine settled clear after being passed; in the other it remained turbid, resembling urine undergoing decomposition. In the former the symptoms of vesical disease were cured or greatly relieved by salicylate of soda, the bacteria disappearing entirely or almost entirely with the relief of symptoms. In the second class no effect was produced on symptoms or bacteriuria by the same drug.

The writer of the paper cited cases from his own experience illustrating these two forms of disease, and confirming Dr. Roberts' conclusion as to the effects of the salicylates.

In two cases of the second form of the disease it was pointed out that for months before the development of acute symptoms the patients complained—in one case of foul smelling urine and slight vesical irritability; in the other, of slowness and effort in the act, the urine being turbid on being passed. Slight vesical atony, spontaneous invasion of the bladder by bacteria, whose multiplication in that organ was rendered possible by the residual urine and final transformation of slight irritation into an acute inflammation under the influence of apparently trifling exposure, seemed to be the most rational explanation of the clinical course of these cases.

The treatment consisted, first, in doing away with the vesical atony by the use of strychnine and cantharades, and possibly electricity. The tenesmus attending acute symptoms might in itself be a useful factor in stimulating vesical contraction. It should not be entirely suppressed by too free use of narcotics, nor should large vesical injections be used for the same reason. The bacteria would vanish when the bladder became able to fully empty itself, and when the products of inflammation which furnished appropriate nourishment for them ceased to be formed under the influence of appropriate treatment. Injections of antiseptics, strong enough to be bacteriacidal, were too irritating. All the bacteria were not reached, and the inflammation was aggravated by them.

The cases cited were probably common varieties of disease. The existence of slight vesical atony might be difficult to demonstrate in the female, and was probably more frequent than the current literature would lead one to expect. The recognition of bacteriuria, especially of the second variety treated by Dr. Roberts, was of value as pointing with great probability to this condition.

DR. VAN SANTVOORD'S PAPER.

Discussion.—Dr. Martin considered the cases reported by Dr. Van Santvoord similar to three that came under his observation. They were in females, and the condition of the urine in all three showed the presence of bacteria, and in two of pus. They were put on the internal administration of salol, benzoic, and boracic acid, three grains of each, four times a day, and all three got well. He mentioned this to bear out the statement that this condition is not so uncommon as was supposed.

Dr. Manley said that it was now the generally accepted view that bacteria are the exciting agents in the production of inflammation in those parts which have a direct communication externally, as, for instance, the pharynx, nasal passages, bladder, rectum, etc. Accepting this theory as valid, the treatment

[1] Abstract of paper read before the Harlem Medical Association October 1, 1890.

would be very simple. First, destroy these bacterial elements, and second, to prevent their multiplication or return. The great difficulty is to get something which will act as a bacteriacide, and not at the same time poison the individual. Then get the parts in such a condition as to make it impossible for the bacteria to thrive. Dr. Van Santvoord, he thought, placed very little reliance in direct applications—internal antisepsis of the bladder by internal agents. His experience in dealing with vesical troubles had been quite contrary to the doctor's in that respect. There were two things he found of great value in vesical irritation—drinking large quantities of water, which not only serves as a diluent in the bladder, but washes out whatever micrococci may lodge in the mucous membrane of that viscus, and next, the use of ordinary diuretics, such as buchu and squibbs. They know these act energetically on the kidney. He thought it would be well in cases that resist all medicinal treatment to resort to the method recommended by Dr. More Madden, of Dublin, giving rest to the sphincter by surgical interference, or do a suprapubic operation, as advised in the case of an adult by McGuire, of Richmond, Va. If the disease was of microbic origin, the way to do was to find the proper antiseptic, and then surgical interference would not be warranted. He had been very much instructed by the paper of Dr. Van Santvoord, and felt the association would appreciate its true value.

Dr. Van Santvoord stated in conclusion that he did not wish to be understood as advocating the view that spontaneous invasion of the bladder in these cases by bacteria was the sole cause of cystitis. He did not regard bacteria as the primary and only cause of cystitis. It was, of course, the general opinion that vesical atony was a predisposing cause of cystitis, and in the paper he wished to emphasize that he believed it to be *frequent*. He supposed bacteria get into the bladder when there was a little residual urine and multiply. Probably a slight amount of multiplication does no harm if there was not enough residual urine to set up irritation. As for the cases being common, he believed they were very common, and on that account were of interest. Dr. Roberts has stated there was a certain class of cases in which the salicylates were of the greatest value, while in others they were of no value at all. The difference between the two classes of cases was that in one there was probably considerable atony of the bladder, while in the other there was none. In the latter case it was, he thought, a question whether bacteria had anything to do with the symptoms.

Society Notes.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Special Meeting, September 16, 1890.

G. W. Allyn, M.D., President, pro. tem., in the Chair.

Dr. W. C. Bane: On the 13th of February last, there was brought to my office, upon the recommendation of Dr. C. B. King, a rather delicate girl, whose vision was apparently very defective. Upon my record-book I find the following memoranda:

L. R., aged fourteen. Use of eyes for near work causes them to ache, also smarting of the eyelids. Dread of light, or photophobia, during the past three weeks. General health not good. Rather tall for her age, and anæmic. Had never menstruated. History of vision always being defective, but worse during the past year. Examination revealed slight congestion of the palpebral conjunctiva. Vision R. & L. E. $=\frac{1}{36}$ or $\frac{4}{140}$. With the ophthalmoscope the fundus of each eye appeared normal.

Office hours being up, I prescribed for the congested conjunctiva some boric acid in aq. menth. pip., with the understanding that she should return in a few days. February 20, I tested the eyes with lenses previous and under a mydriatic, with but slight improvement in vision. The patient seemed intelligent, and the eyes appearing to me to be quite normal, I was at a loss to know why the vision did not correspond. In my perplexity I placed in front of the right eye—the left one being shaded—a-4.50 D. cyl., which at axis 120° enabled her to see $\frac{1}{6}$, Snellen, the card being placed within a meter of her eyes, as beyond that distance she seemed unable to name any of the letters on the test-card. At this point I stopped and requested that she return in a week or ten days.

March 3, 1890. With the test-card at the proper distance, twenty feet, I commenced where I left off at the last examination, by placing the — cyl. in front of the right eye. At this time she could see $\frac{6}{60}$ or $\frac{20}{200}$. I now gradually reduced the strength of the — cylinder, by placing plus cylinder in front of it. Gradually the patient's vision came up, until when I had the equal of a plane glass in front of the eye, the vision was $\frac{20}{20}$, or normal. I next proceeded to correct the left eye, and in doing so proceeded as with the right eye, and when the lenses equaled a plane glass, she could see $\frac{20}{20}$. Her near vision was likewise quite normal. Without stating to the patient what glass was in front of her eyes, I wrote the following:

℞.—R. & L. Plano.
P. D. 60 mm.
Constant.

I now prescribed for her, with the consent of Dr. King, what is familiarly known as Basham's Mixture.

On March 10 the patient returned, eyes well opened, photophobia slight. Vision normal.

April 18. Patient has continued to take the tonic. General health much improved. Continues to wear the spectacles. Vision normal.

The case was an interesting and instructive one to me. She was so innocent in her manner, and seemingly honest in her answers to my questions, that I did not feel that I ought to say to her that I had reason to doubt her. The expense of the examination was being borne by a friend of hers.

Dr. Allyn: Two years ago a boy, but eight years old, was brought to my office complaining of trouble in seeing the blackboard in school. Without a glass before the eye he could not see the test-card, while a simple plane produced normal vision. On removal of the plane his vision disappeared again. This I repeated until satisfied that there was no trouble with his eyes.

Dr. Painter: I have a case with one interesting point. It is of a married woman, aged twenty-seven, who came to me with a history of suppurative tonsilitis. One tonsil went to the formation of an abcess, which broke, the other going through the inflammatory process, but not forming an abscess. A month subsequent to this she came to me complaining of a difficulty of deglutition and impossibility of swallowing liquids; they would be ejected through her nose; and in extinguishing a lamp the expired air would go through her nose, not out of her mouth. She had a marked nasal intonation. The soft palate was

abnormally flaccid, and insensible to the touch of the probe, as was also a portion of the pharynx. She was treated with electricity (the Farradic current), and was given strychnine, the doses being increased until the physiological action of the drug was brought about. The only point of interest in the case is that the suppurative form of tonsilitis had this sequel of paralysis. She got well speedily, as probably she would have without any treatment. She was pregnant seven months, and badly needed liquids, of which she was deprived by the paralysis, and rest to her mind, so that active treatment was indicated.

DR. W. C. SHAW: A child, born the 16th of July. A few days after birth the mother called my attention to a lump in its throat just above the hyoid bone. Some time afterward it increased in size, and I punctured it with a small instrument, and clear fluid passed through. I gave some syrup of iodide of iron and phosphate of lime, a few drops every day. In about two weeks she brought this child to me a second time, with this cyst refilled. Last night she brought the child in the third time. I opened the cyst, and, instead of a clear fluid, got bloody fluid. It might be called a congenital cyst.

A boy, eleven years of age, was picked up, injured in the collision of a buggy with an electric car. He was bleeding profusely from his nose and his left ear. He had laceration of both ears and a scalp wound. I remarked at the time that the boy might pass for one suffering from a fracture of the base of the skull. Two or three days after there appeared an ecchymosis on the left of the eyelid, and extending up over the forehead. I was dressing his ear and made a little pressure over the meatus, and he complained of severe pain in his ear. He was also deaf in the left ear; could not hear a watch tick an inch from his ear. He gradually recovered, and did not have serious complications, if he had fracture of the base of the skull. But now, to-day, I called at the house to make my last visit, and his mother spoke of his going down last evening from the steps to the pavement, and as he stepped on the pavement he complained of a jarring in his head again, and of quite a severe pain in that ear. I still think that boy has a fracture of the base of the skull.

While speaking of injuries in the region of the neck, I have lately noticed in cases in this neighborhood of cutting of the throat, that some of the surgeons have performed tracheotomy. I rather think that that is an addition to the injuries, and more likely to do harm than the original trouble. I do not think tracheotomy necessary. One hospital case I remember was a curiosity. Every time any one wanted to see the vocal cords work, they would go into the ward; we would remove this man's bandages, turn over his neck, and get him to exercise the vocal organs. We could see the vocal cords working nicely. Now, if that case had occurred in this neighborhood, some of the surgeons would have operated upon it and introduced a new danger.

DR. O'BRIEN: I am reminded to report a case which occurred in my practice a couple of weeks ago. A child was playing in a new building, and had climbed up a partly-built stairway and tumbled over to the ground below, a distance of fourteen feet, and fell upon some loose stones that lay there. I found the child had a contusion on the left parietal bone, and also at the temple. There was considerable swelling and a sub-cutaneous bleeding, so that the skin was quite tense over the point of injury, and I was unable to determine whether the skull had been fractured. However, there was complete right hemiplegia. The injury was on the left side of the head. The child could not move the right hand or foot at all. Was entirely speechless, and the tongue lay on the right side of the mouth, and if asked to protrude it, protruded to the right. The eye-balls turned to the right. There was no stertorous breathing. Believing that it was probably an injury to the meningeal artery, and hemorrhage, I suggested a consultation, and that Dr. McCann be called. He came in a few hours, and she was by that time slightly improved. She could just move the fingers of the right hand, but could not be induced to take anything in her hands. The doctor advised waiting, and after two or three days the movements began to return, and the child recovered ultimately complete use of the limbs. An interesting observation I made was that when it began to speak again it had not forgotten the nouns, as most cases of cerebral injury do. The child asked for what it wanted, and constructed a complete sentence the third day after the injury. I think that in the case there had not been much hemorrhage, and in all probability the explanation of it was that the blow received by the parietal bone had simply contused the cerebral substance.

DR. AYRES: In regard to Dr. Shaw's second case, in which he seems to think the boy suffered fracture of the base of the skull, I should differ with the doctor. It does not appear the symptoms were severe enough to venture an opinion of that kind. The vital centers are most likely affected in fracture of the base, and death is almost certain to result. I would mention here that a series of extremely interesting articles have been recently published in the *Lancet*, on fracture of the skull. In Dr. Shaw's case, I think some slight hemorrhage was the nature of the trouble. With regard to the case on which Dr. McCann did not operate, it was certainly an interesting one, and shows the importance of going slowly with regard to using instruments for cutting into the brain. I suppose many surgeons would at once have proceeded to operate. I am rather inclined to think there was in this case a little hemorrhage.

DR. MCCANN: The case was one in which there was probably a minute hemorrhage, or that condition which is recognized as commotion or contusion of the brain. At the time I saw it, the child had paralysis and loss of speech, but still there was nothing which warranted brain proceedings. We, therefore, deferred operation, with the result the doctor has stated. The bones of a child are so very flexible, breaking with such great difficulty as compared with the bones of an adult, that you can readily understand how a certain amount of bending or yielding under force might occur without an absolute fracture of the skull, and still lead to contusion of the brain substance, which would bring about a paralytic condition more or less permanent, but which is liable to be gotten rid of in children. The brain is likely to accommodate itself to pressure. In a simple fracture of the skull, even with some depression and without symptoms, I should hesitate about applying the trepine in a child, whereas in an adult I should not hesitate if there was a marked depression. Of course, in a compound fracture of the skull in a child, I should not hesitate resorting to operation and an endeavor to remove the depressed fragments of bone, if necessary, to give outlet to any blood which might be concealed, and should not hesitate to open the dura for the purpose of relieving the pressure. But where you have to deal with a simple fracture with marked symptoms, but without any positive evidence of fracture at a given point, I think it is well to go very

slow in operating upon a child. I remember an instance where the parietal bone was driven down upon the brain over the ear, in which the child lay insensible for three days, and which, after elevation and removal of the bone, the cerebral symptoms passed off, and the child recovered entirely. I reported to this society, a few years ago, an instance in which a large portion of the parietal bone was driven down on the right hemisphere of the brain, destroying the right motor center for the arm and for the leg and face, but not destroying the speech center, in which there was, I think, half an ounce of brain substance torn from the brain, with an immense tear in the dura, leaving a cavity into which I passed my little finger to search for fragments of bone in the brain. Without any expectation of recovery, I introduced a drainage tube into the brain and stitched the wound up. Very much to my astonishment, my patient recovered, and with power in the leg sufficient to enable him to walk. He has never recovered power in the arm. His speech has not been seriously affected. I cannot see that there is any necessity for treating a fracture of the skull as an open wound. The dangers of sepsis are very greatly increased, whereas by closing the wound and draining, thereby giving exit for any fluid which may flow out as a consequence of the damage, certain sources of danger are eliminated; and at the same time you can protect your wound effectually, so that you leave your patient very much as if he suffered from a simple fracture.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

FOR gonorrhœa Shoemaker advises cleaning the parts with a hot solution of common salt, and the use as an injection of three grains of corrosive sublimate to six ounces of water. Internally he advises the use of terebene in ten-drop doses three times a day, in capsule or on sugar. In a gleety condition the combined use of terebene and belladonna, he thinks is probably the best treatment. He instanced a case of gleet which had been treated by all the best venereal specialists in this country, which was finally cured by Ricord, of Paris, by the use of belladonna in one-drop doses four times a day, increased to three drops three times a day. Terebene, he says, has not only a most decided action on the gonococcus, but has also a soothing and sedative influence on the mucous membrane of the urethral tract.

In a severe case of acne associated with rosacea Shoemaker advised and prescribed as follows: Wash the face in hot water, as hot as can be borne. Drink a cupful of hot water upon retiring and upon rising. Have the pustules punctured by a physician; the incision thus produced will not cicatrize, whereas, if they are squeezed, they heal with a scar. Take internally:

℞.—Liq. potassii arsenitis,
Tr. nucis vomicæ.....āā gtt. lxxij.
Aloini..... gtt. ij.
Aq. menthæ pip.....q. s. f℥iij.
M.—Sig. f℥j ter in die.

Apply externally:

℞.—Acidi borici..... ℈j.
Lanolini..... ℥ij.
Ol. eucalyptol..... gtt. v.
Ung. zinci oxidi..... ℥j.
Bismuthi subnit..... ℥j.
M.—Sig. Ft. unguentum.

For a case of herpes induced by a remote traumatism Shoemaker prescribed, internally:

℞.—Ext. malt..... f℥j.
Elix. ferri lactatis..... .. ℥ss.
M.—Sig. This quantity thrice daily.

Externally, to allay the inflammatory action of the integument:

℞.—Cocainæ .. .. gr. ij.
Sulphuris subl..... gr. x.
Zinci carbonatis..... ℥j.
Marantæ..... ℥j.
Pulv. camphoræ..... gr. x.
Ung. aquæ rosæ,
Ung. zinci ox. benz.....āā ℥ss.
M.—Ft. ung.

A few pointers on the method of urethral injection: Never use a glass syringe. I give preference to Goodyear's rubber syringe, which has bulb shoulder on its nozzle, thus preventing the nozzle from entering too far into the urethra. Warm the injection fluid before using. Do not overfill the urethra. Never stroke under surface of urethra after injecting, as is advised in the books. Never use injections until the acute stage is passed. Never give injections which irritate or burn.—*MacConnell.*

Continue medication for gonorrhœa ten days after disappearance of all symptoms.—*MacConnell.*

MacConnell gave the following as the latest and best internal treatment for gonorrhœa:

℞.—Salol ..... ℥j.
Oleores. cubebæ..... ℥j.
Copaibæ..... ℥j.
Aluminis..... ℥iv.
Pepsinæ sacch..... ℥ss.
Ol. gaultheriæ..... gtt. x.
M.—Ft. capsul No. xx.
Sig. Two every three hours.

This treatment prevents the occurrence of gonorrhœal rheumatism. The salol is slightly decomposed by the gastric juice, but is actively decomposed by the intestinal juices into salicylic and carbolic acids, thus acting as an antiseptic in the urinary tract through which it is eliminated.

In delivering a child allow the membranes to remain intact until the head is delivered. The hydrostatic pressure of the fluid in the sac aids in the dilatation of the vagina and perineum.—*Montgomery.*

Where astringent injections are used in the vagina albuminates are formed, which accumulate and decompose unless the vagina is daily washed. For irrigation use solutions of zinc chloride, or of lead acetate, forty grains to the ounce.—*Montgomery.*

A granular vaginitis occurs in women of full habits. This should be corrected. Reduce their diet, otherwise topical treatment will be inert.—*Montgomery.*

Vagrant pains are either due to a toxic element floating in the blood, or to some systemic cause acting generally.—*Waugh.*

For an ulcer of the stomach Waugh prescribed 1-100 grain of the arsenite of copper to be taken after meals, continued for a long time.

Prof. Keyser is not to be prevented by dark and cloudy weather from giving a good, practical eye clinic. While abroad this year he purchased an electric illuminator, by the light of which he can perform all eye-operations, however dark the sky.

For a woman fifty-two years old, complaining of a loss of appetite, vagrant pains, flatulency, constipation and "load on stomach" after eating, Waugh prescribed as follows, with a view to increasing the digestive function and the peristaltic action of the intestines:

℞.—Maltine..... fʒss.
Cascara sagradæ..... ʒss.
Strychninæ sulph..... gr. $\frac{1}{60}$.
M.—Sig. One dose, repeated thrice daily.

Do not make cold applications to a crushed limb, lest sloughing be induced.—*Goodman.*

For a child, eight years old, suffering from debility after an attack of acute Bright's disease, Hollopeter prescribed the following:

℞.—Tr. ferri chlor..... fʒj.
Acidi acetici..... fʒij.
Strychninæ sulph..... gr. ½.
Liq. ammoniæ acet..... fʒiss.
Syr. tolutani.....q. s. ad. fʒiij.
M.—Sig. ʒj every four hours.

Inhalations of chloroform are invaluable in arresting convulsions in children of two years or under. Give them a whiff of it while in the convulsion. The paroxysm having been broken, the following should be given to prevent recurrence:

℞.—Sodii bromidi..... ʒj.
Chloral hydrat ..... ʒss.
Aq. menthæ pip.,
Syr. tolutani.....āā fʒiv.
M.—Sig. fʒss.; one every half hour until child is quieted down.

—*Hollopeter.*

Keyser presented a case of divergent strabismus, due to hypermetropia. As a rule, he said, divergent strabismus is due to myopia, while convergent strabismus is due to hypermetropia. Concerning the prevention of strabismus he remarked: "A child never sees anything sharply until it is three or four years of age, according to its precocity. If at this age any error of refraction be corrected, nature will correct the squint. There should be no hurry about operating. Glasses should be worn six months to a year before an operation is thought of. If you operate too early a squint the opposite of which you intended to correct may be the consequence."

In needling a soft cataract, known as the discission operation, the first operation should consist of but a gentle puncture of the capsule, made by a drilling motion of the needle. Better do a dozen such operations than to slit the capsule and lose the eye. The aqueous humor will pass through the puncture into the capsule, producing pressure and consequent absorption of lens.—*Keyser.*

In removing a dressing from an injured eye do not do so in a bright light.—*Keyser.*

A teaspoonful three times a day of the Elixir Ferri Pyrophosphatis will remove styes.—*Keyser.*

For eczema of the limbs, due to a varicose condition of the veins, give of the extract of hamamelis, gtt. xx., in a teaspoonful of glycerine, t. i. d., and apply the following ointment, supporting the limb with a bandage:

℞.—Beta naphthol..... gr. x.
Camphoræ ..... gr. x.
Ung. hydrarg. nit..... ʒij.
Ung. aquæ rosæ..... ʒj.

—*Shoemaker.*

For eczema marginata give hoang nan internally, and apply to affected parts:

℞.—Ol. cadini..... ʒj.
Acidi borici..... ʒss.
Ung. zinci ox. benz..... ʒj.
Hydrarg. ammon..... gr. x.
Ung. aquæ rosæ..... ʒss.

—*Shoemaker.*

UNIVERSITY OF PENNSYLVANIA.

IN a recent lecture on dyspepsia, Dr. Pepper said: "One of the most frequent causes of dyspepsia is the constant use of irritating substances, such as tobacco, alcohol, and highly-seasoned food. Tobacco and strong tea and coffee act both by depressing the nerve force of the stomach and, if swallowed, by directly interfering with the digestive processes. It will not be disputed by any fair-minded person that tobacco, tea, and coffee are injurious when taken in excess. It must be admitted that the majority of men, in a state of health, can use a certain amount of tobacco without injury. This amount varies with the individual, but is in any case small. I cannot speak too strongly against the filthy and disgusting habit of chewing tobacco. It is hard enough for a fastidious patient to endure a physician whose clothing reeks with the perfume of choice Havana cr cigarettes, but when the mustache is stained with tobacco juice, and the doctor is spitting while in the sick room, it is unbearable. No physician ought to be seen with a quid of tobacco in his mouth. There is no doubt that some men are benefited by a moderate use of tobacco. They are lacking in will power, and must have some vice or habit. The tobacco habit is the least harmful, makes them happy, and keeps them from something worse.

"The habit of expectoration is a distinctively American habit. It is seldom seen abroad, but is so common in this country as to invariably attract the notice of foreigners. It is an entirely useless habit, nothing being formed in the mouth during health that is not intended by nature to go into the stomach and aid in the digestive processes. Every bit of saliva ejected from the mouth is a direct robbery of the stomach."

Dr. Hirst gives as an equivalent of human milk.

Cream..... fʒiv.
Cow's milk..... fʒij.
Water..... fʒj.
Milk sugar..... gr. 1.

Sterilize by steaming for twenty minutes, and before using, add lime water, fʒij.

Dr. Hare gives for acute stage of bronchitis in children:

℞.—Tr. aconiti..... gtt. xij.
Syr. ipecac ..... fʒss–j.
Liq. potassii citratis.....q. s. ad fʒiij.
M. and S. One teaspoonful every three hours.

For the later stages:

℞.—Ammonii chloridi..... ʒj.
Ext. glycyrrhizæ fl..... fʒiv.
Aquæ dest.....q. s. ad fʒiij.
M. and S. One teaspoonful three times a day.

A favorite dispensary prescription for diarrhœa is:

℞.—Salol..... ʒij.
Bismuthi subnitratis ..... ʒiv.
Mist. cretæ.....q. s. ad fʒiij.
M. and S. One teaspoonful every two hours.

ARE THE PROTOZOA IMMORTAL?

SOME years ago Weismann made the remarkable claim that protozoans were not subject to the ordinary laws governing animate objects, in that they did not experience death, except through accident. These unicellular organisms reproduce by bipartition; each half becoming a new creature; and as this process is continued indefinitely, there are really no deaths in the protozoan world, except such as were due to violence. The same thing is true as regards the sexual cells in metazoans. While the somatic cells in time perish, the sexual cells belong to the protozoan type, multiply by fission, pass from generation to generation, through the mediums of the fecundated ovum, and are hence immortal.

Quite recently, M. Maupas has attacked this theory, and claimed that natural death, due to senile decay, obtained among the infusoria. In 1860 Balbiani observed that reproduction by fission was limited by the simultaneous death of all the individuals belonging to the same cycle, by the renewal of life through the occurrence of sexual generation, thus beginning a new cycle, or finally by encystment, which causes a temporary interruption of the process of fission.

Now, Maupas shows that no element in the infusoria can live indefinitely and independently. The first visible evidence of degeneration is a reduction in the size, with change of contour. The nucleus is the first to undergo atrophy, and finally disappears. But, as Binet observes (*The Monist*), when the vitality of the infusoria has become weakened by a considerable number of organic reproductions, and the animalculæ are upon the point of dying a natural death, a new biological phenomenon can intervene, rejuvenating the organism, and rendering it capable of reproducing itself anew for a long series of generations. That phenomenon is fecundation. And since the substance, the protoplasm, of the rejuvenated individual escapes death, a new argument might be found in these last mentioned facts for the theory of the immortality of infusoria.

The question is at bottom whether the individual, after conjugation, is essentially the same as before conjugation, or whether it constitutes a new animal. In that the solution rests. Now, the new element that the individual acquires by the act of conjugation, is the male pronucleus of its partner. In addition, it loses the greater part of its old accessory nucleus, and the whole of its old principal nucleus. In return, by way of compensation, it preserves the integrity of its protoplasm and of its other organs. M. Gruber believes the physical identity persists in spite of these modifications. M. Maupas maintains the contrary.

The thesis of Weismann regarding the immortality of infusoria eludes a direct refutation. It is neither confirmed nor overturned by observed facts.

DIXON ON INOCULATION FOR TUBERCULOSIS.

ON Monday our reporter called at the Academy of Natural Sciences to see Prof. Dixon; who received him with his usual courtesy, but at the same time requested the privilege of proceeding with his work, as he was not blessed with a corps of assistants.

While he was busily engaged in making inoculations, he was asked what he thought of the results of Prof. Koch's latest experiments, as cabled from Berlin.

"Why, if it be true that he has cured human beings of tubercular phthisis, the result is most gratifying to all those who are working for that end, and, while I fully realize the possibility of his being able to do so, judging from the results of my own experiments, at the same time I am disposed to doubt the truth of the reports."

"On what grounds?"

"Because I believe Prof. Koch to be a man who is working, not only for the sake of science, but also for the cause of humanity, and that, had he arrived at results sufficiently definite to justify the inoculation of human beings, he would have announced the fact, not only to the bacteriologists of the world, but the whole of the civilized globe would have received a full detailed account of his methods, so that we might all take our part in relieving the great mass of suffering humanity."

"If the experiments are successful on animals, why should they not be equally so with the human family?"

"Because, sir, the more experience that physiologists have with the action of drugs on animals, the more they recognize that what is true of one group of animals is not necessarily true of another group, and to a limited degree this is the case with individuals. Micro-organisms are often innocuous to man, but virulent to animals, and vice versa. Take for example the great immunity that some races enjoy from yellow fever."

"Is there any plausible theory for the results that you are seeking to accomplish?"

At this point the Professor was becoming warmed up to his subject, and seemed anxious to enter fully into the question, but, as he was engaged upon some experiments which he was anxious to carry out at once, he asked the reporter to call later in the day, when he might be able to give him a paper dealing more fully with the results of his investigations than he was able to do at that moment.

Upon the reporter calling again, the Professor handed him the following answer:

"Many theories have been advanced, but none fully expounded. When, in my article in the *Medical*

and Surgical Reporter of September 6, 1890, I acknowledged that it was quite impossible to show how the immunity was produced, I only confessed our ignorance in regard to the processes producing immunity by inoculation. At the same time I have been directed by theories. When one of England's greatest medical men, Dr. T. Lauder Brunton, was delivering the Croonian Lectures at the Royal College of Physicians, of London, I was much impressed by the manner in which he treated the subject he was discussing, which was that of 'Chemical Structure and Physiological Action.' He referred to Mendelyeff, who had expressed the view that chemical affinities would soon be brought under Newton's third law of motion, and that according to this idea chemical compounds and solar systems are built upon the same plan. For example, he compared methane, which consists of carbon and four hydrogens, with Jupiter and his four moons. This pictured the atoms of hydrogen moving around the atoms of carbon. This he followed up by explaining the chemical constitutions with what he termed a homely simile—a penknife with a number of blades for various uses. When he first produced the knife the blades were all closed, representing an innocent arrangement, but as soon as he opened its many blades he reminded his audience that it had become a dangerous instrument, so that by altering the relative position of its parts without any change in its composition, there had occurred a complete alteration of its character.

"When Dr. Brunton had finished his simple, yet forcible illustration, my thoughts wandered to what was then my pet subject, namely, the prevention or cure of tubercular phthisis. I wondered whether or not a changed form of what we believed to be the tubercle bacillus was of the same composition as the usual forms found in animal tissues, but with its component parts holding a different relation to each other, and probably harmless to the animal economy, yet when held in such relationship capable of producing that which would break up the atoms of the tubercle bacillus.

"This was a speculative idea, which of course was not capable at the time of being worked up into a complete theory, but protracted experiments were commenced and followed out as energetically as possible under a very heavy strain at the University of Pennsylvania. During the work in this direction, which has been since uninterruptedly carried on, other theories have not been lost sight of, as for instance that of leucocytes and also that of phagocytes, which are thought to possess the properties of destroying bacteria; now in a great number of tissues they do not possess this power, unless they have first been educated to secrete by attenuated virus, a chemical product deadly to the pathogenic organism.

"Another theory is that the germicidal quality of the normal tissues is sufficient to combat pathogenic bacteria.

"Another most interesting theory is that advanced by Dr. J. W. McLaughlin, entitled 'An Explanation of the Phenomena of Immunity and Contagion Based upon the Action of Physical and Biological Laws.' The explanation of the phenomena of contagion, which one theory offers, is based upon the application of the laws of wave motion to the motion of complex organic molecules.

"The author states that the striking similarity which is seen between fermentation and contagion has led many observers to believe that the latter, like the former process, is caused by microscopic organism. As there are many kinds of fermentation, each kind resulting from the action of specific organisms—for example, alcoholic fermentation is caused by the yeast plant; acetic fermentation by the micrococcus aceti; butyric fermentation by the bacillus amblyo-bacter, etc.—so it is claimed that each specific infection has its specific bacterium or bacteria. I do not think that it can be claimed that only one species or variety of bacteria will produce a specific infection; for example, a specific infectious fever. It is well known that fermentation—alcoholic, acetic, or butyric—may result from the action of more than one kind of ferment, or bacteria. Hence, if the analogy between fermentation and contagion is sound, there are grounds for believing that more than one kind of bacterium may cause a specific infection; for example, diphtheria, cholera, and other infections may each be caused by one or more kinds of bacteria.

"He goes on to say that the principles involved in fermentation are the same regardless of the exciting cause, and that the products of fermentation will largely depend on the molecular structure of the exciting ferment.

"He then proceeds to point out the striking similarity in phenomena of fermentation, as set forth, and the phenomena of contagion. Both are caused by one-celled vegetable organisms; these cells in each case are microscopic in size, and can be conveyed from place to place in various ways that will readily suggest themselves, and, therefore, require no special mention.

"The cells of bacteria, like the cells of the yeast plant, excite fermentation and decomposition when they are suitably environed. In the same manner that yeast-cells decompose sugar into alcohol, the cells of the micrococcus nuthificans convert ammonia compounds into saltpeter, the cells of micrococcus lacticus convert sugar into lactic acid, and pathogenic bacteria-cells convert albuminoid molecules of the blood or tissues, of man and animals, into poisonous substances, ptomaines or toxines.

"And, again, as alcohol is poisonous to the yeast-cells, and will arrest the fermentation which they excite, and by which it was produced, so ptomaines and toxines, the product of infection created by the cells of pathogenic bacteria, poison the bacteria which caused their existence, and arrest the fermentation, or infection, which gave them life.

"And finally: As the yeast-cells can be so modified in their molecular structure that they can be caused to grow and multiply in malt solution without producing alcohol, in a similar manner the cells of some pathogenic bacteria can be so modified by 'attenuation,' in various ways, that are not only made harmless to man, but become a vaccine by which protection from the virulent microbes may be secured.

"In speaking of cells, he says: An elementary substance is the simplest known condition of matter. An atom is the ultimate part of such substance. A molecule is the smallest division of a compound substance, which has the properties of the substance.

"Each and every atom has a natural period of vibration from which it cannot be separated.

"Force, the efficient cause of all physical phenomena, is motion—of atoms, molecules, or of mass. Attraction, light, heat, and electricity are manifestations, or modes, of one and the same force; they are co-ordinate, and subject to the laws of transmutation of energy.

"As atoms have their equivalents of motion—for example, their laws of attraction, repulsion, and combination—which are inseparable from them, it

follows that, when atoms combine to form complex substances, each one carries into the combination its equivalent of force or motion; this may be modified by the motion of associate atoms, but is never lost, and when the dissolution of the compound takes place, the departing atoms carry with them the same amount and kind of motion which they had originally.

"All atoms, whether combined or uncombined, are in constant motion.

"The atomic motions of each element observe definite periods of time in their recurrence.

"Atoms of different elements observe periods of time in their movements.

"The author claims that the cells contain molecules, and that the molecular movements are governed by fixed laws, and are not the result of chance or hap-hazard action. He says: Picture in your mind's eye the marvelous mechanism of one of these little cells, with its contained molecules in active motion; each other by spaces which, although infinitely small to our comprehension, are really large when compared with the size of the molecules; remember, also, that the molecular movements are not of the hap-hazard sort, but are governed by fixed laws, and that while similarly-constructed molecules have similar modes of motion, there are marked differences in this respect between molecules of dissimilar construction. As the molecule receives its motion from its constituent atoms, the cell must receive its energy from its constituent molecules. Remember that atomic and molecular motion constitute force, so that when we speak of cell-motion we mean to imply cell-force, its power to do work, and the explanation which is offered will follow almost as an inevitable result.

"The explanation of differences in cell activities is based upon the law that force, the efficient cause of all physical phenomena, is motion—atomic, molecular, or molar; that heat, light, electricity, attraction, and repulsion are simply modes of one and the same motion, which can be converted and changed from one into the other. Now, there is a marked difference in the kind of work which these different forces or modes of motion can do. For example: Electricity can decompose many substances that light does not affect; on the other hand, light decomposes other substances over which electricity has no power; while heat, in its decomposing power, has a much larger range of action than either of the others.

"This can be the better understood by one of his illustrations. 'When waves of light, or heat, or water meet other waves of the same substance, in such a manner that the crests of one set will correspond with the crests of the other set, and the troughs of one will correspond with the troughs of the other, the waves will be enlarged—increased in amplitude.'

"Now, it is assumed that different varieties or species of cells have molecular vibrations, which, in their periods of recurrence, are distinctive of such species or variety; hence the molecular movements of cells are influenced in a certain way by other cells whose molecular periods of vibration coincide with those of the first in point of time. The wave-crest and trough from one cell striking the molecular waves of another cell less firmly fixed in its structure, crest to crest and trough to trough, the motions of the first would necessarily increase the swing of the second until the cell-molecules were swung beyond their attractions and the cell disrupted. The cell-molecules thus set free would recombine, in accordance with chemical laws, to form simpler compounds. For example, in the vinous fermentation, the molecular combinations of the yeast-cell are so timed in their motions that they can swing the molecules of sugar, held in solution, beyond their chemical attractions, and thus cause a disruption of the sugar; at the same time, the molecules or atoms thus liberated recombine to form a simpler compound—alcohol. Other cells cannot do this work, for the reason that their molecules do not vibrate in the required periods of time. In the same manner the micro-coccus aceti decomposes alcohol into acetic acid, and other bacteria perform their special kinds of work, and are incapable of doing the work of other varieties. In the same manner, pathogenic bacteria shake apart certain cellular albuminoid molecules in the blood or tissue of man and animals, while the recombination of molecules thus liberated form poisonous alkaloids called ptomaines and toxines, which are the immediate causes of the symptomatology and pathology of infectious diseases. The decomposition of albuminoid molecules by cell metabolism, principally bacteria cells, and the influences which the products of this action, ptomaines and toxines, have in the causation of disease, is a subject of greatest importance to the physician.

"'The albuminoid molecules, from whatever source derived, present certain lines of separation, like the lines of cleavage in crystals, along which they are most easily disrupted or shaken apart by cell-vibrations; hence the character of the decomposition product depends along which of these lines separation has taken place.

"'At least three distinct series of chemical bodies are formed, viz., an acid series, an aromatic series, and a basic series. Out of the innumerable products arising from the action of the bacteria-cells upon albumenoid molecules, and which have been extracted and studied, will be mentioned indol, cresol, and skatol, in the aromatic series; creatine, in the basic; and uric acid, in the acid series, serving only as mere examples.

"'Cells other than those of bacteria are also capable of decomposing albuminoid molecules, and thus produce poisonous substances, *e. g.*, in the physiological changes from albumins to peptones there is a change from innocent to toxic bodies; this may be illustrated by the hypodermic injection of the digestive leucomaine of fibrine by pepsin. It occurs practically when, after the too hearty meal, the liver is unable to care for the excess of digestive leucomaine, and they escape into the general circulation, producing somnolence, lassitude, or even stupor.

"'On this subject, Dr. Joseph Leconte says: The leucomaines, although formed by normal physiological process, are highly poisonous and inimical to health, unless speedily eliminated by appropriate organs. If, now, there should be a failure to eliminate these toxic elements, the results would be similar to those produced by disease germs, except that they would lack the quality of contagiousness, because they are not due to the presence of microbes. The liver is the organ principally concerned in the elimination of leucomaines.

"'If alkaloids, by the conjugation of "S" biliary acids, if carbohydrates, they escape the liver, and are taken care of by the blood and pancreas. If belonging to the class of phenols, they are combined with a sulphuric radical, and when that gives out are then combined with a glycosuric acid, and thus rendered innocuous.'"—*Journal of the Amer. Med. Association.*

"It is thus shown that fermentation may be the result of molecular motion, and that this process would take place whether the necessary vibrations originate in yeast-cells, bacteria-cells, or digestive ferments, which are the efficient cause of normal digestion. The principles involved in each case, the modus operandi, are the same in all. At this point, however, the similarity of results existing between the bacteria ferments and digestive ferments ceases. There is an important difference in their biological history, which carries with it an important and practical distinction. I refer to the fact that bacteria and yeast-cells are living organisms, capable of multiplying themselves by the generative act, and hence, in the case of pathogenic bacteria, are capable of inducing contagious and infectious diseases. On the other hand, the digestive ferments are molecular combinations, which have no powers of self-multiplication, and cannot cause disease of an infectious or contagious character. There is a wise and beneficent law of wide application, the operation of which controls the course and duration of infectious fevers; this law is based upon the fact that the products of cell-decomposition are poisons which destroy the cells, or the fermentation, or infection which they excite. Thus, alcohol is destructive to the yeast-cells and the vinous fermentation, while acetic acid, butyric acid, and lactic acid, will arrest the fermentation of which they are the products, and, in the same manner, ptomaines and toxines arrest the infectious diseases, of which they are severally the causes.

"On this subject Dr. Klein says: 'One of the most interesting facts observed in the growth of septic micro-organisms is this, that the products of the decomposition, started and maintained by them, have a most detrimental influence in themselves, inhibiting their powers of multiplication; in fact, after a certain amount of these products have accumulated, the organisms become arrested in their growth, and finally may be altogether killed.'

"Pasteur says: 'Many microbes seem to give rise during their breeding to substances having the property to be harmful to their own growth.'

"It is evident that the periods of time in which occur the molecular vibrations of any given cell, or molecular structure are before the first can swing apart the molecules of the second. Crest must correspond to crest, and trough to trough, before the one set of vibrations can sufficiently increase the other to cause its disruption. When the arrangement is complete *e. g.*, the vibrations of the bacteria-cell coincide in their periods of recurrence with the molecular vibrations of the albuminoid molecular substance, and decomposition of this results, thus liberating its constituent molecules. It is evident that no new compound can form from these molecules unless its periods of vibratory recurrence do not coincide in point of time with those of the bacterium cells, the same influence which disrupted the albuminoid molecules would prevent the forming of other compounds having the same periods of vibratory motion; in fact, they must be of an opposing kind, in order not to be influenced by the bacteria cells. Now, it is again evident that when a ptomaine, possessing a molecular vibration which antagonizes that of the bacteria, accumulates in a sufficient amount, the antagonism will be sufficient to arrest the motions of the bacteria cells, and thus put a stop to the cell-metabolism which they caused—in other words to arrest the disease.

"Perhaps this power, which waves or vibrations have of increasing or destroying similar waves or vibrations, may be better understood by reference to instances where waves of sounds and waves of light thus influence each other. Take, for example, two tuning forks which have equal periods, when sounded each will give out the same continuous musical sound. Let us, however, change the vibrations in one of the instruments, by attaching some substance to it, or in any other way. The two instruments will no longer vibrate together, the vibrations will not coincide in time, hence the sound that will be given off by them will no longer be a continuous musical note gradually fading away, but will be a rising and falling sound. When the two instruments vibrate together, the sound will be distinct. As one vibrates more rapidly than the other, they will gradually part company, and the sounds which they give out will coincide less and less in point of time as one gains upon the other, and becomes fainter and fainter, and disappear when the wave crest of one coincides with the wave trough of the other. After passing the line, the sound becomes gradually more and more distinct, until it again reaches its acmé, when crest and trough coincide to crest and trough of the other side, and thus the sound will rise and fall, depending upon the amount of wave interference or antagonism, until the vibrations are exhausted.

"It is thus seen that sound waves can be caused to so act upon each other that, instead of producing sound, they will cause silence. Illustrations could be given, if it were necessary, to prove that when waves of light are met by other waves of light whose periods of vibrations are one-half wave length behind the first, darkness will be the result. The waves of the one set are quenched or antagonized by those of the other, in accordance with the law of wave interference. This beautiful and important law was discovered by Dr. Thomas Young, one of the most remarkable men the world has produced. Speaking of this law, Sir John Herschel says: 'This principle, regarded as a physical law, has hardly its equal for beauty, simplicity, and extent of application in the whole circle of science.' The principles involved in this law of interference furnish an explanation why ptomaines are inhibitory, and sometimes poisonous, to the bacteria-cells which originated them. The amount of antagonism exerted by the ptomaines, in accordance with this theory, would depend entirely upon the extent of interference which its molecular waves would cause in the molecular waves of bacterium-cells. As the amount of interference in waves of sound and waves of light varies, and thus produces variable amounts of sound from zero up, there are ptomaines whose inhibitory power over the actions of cells differs in the same degree and from similar causes.

"Bacteria-cells, whose wave lengths do not coincide in periods of recurrence with those of any cells, blood serum, or tissue fluids of man, would for this reason be innocuous to man. At the same time they might find, in fluids or tissues of other animals, molecular combinations which these bacteria could disrupt, and for this reason they would be virulent to such animals.

"The third and last means by which immunity can be secured against an infectious disease, is by previously injecting its characteristic ptomaines into the individual, beginning with small amounts and gradually increasing the dose as the individual becomes accustomed to the poison, this means of immunity by the injection of specific ptomaines, is of recent discovery, and bids fair to become of great practical advantage. It already explains what had been previously very obscure, how the pregnant mother

gives immunity, for example, in syphilis, to the child in utero.

"It is generally admitted that solid particles, like bacteria-cells, cannot pass from the mother through the placenta to her child in a normal state of the placental tissues; hence, the fact of the child's immunity secured through the mother was not understood. That soluble substances like ptomaines can pass in this way by osmosis is not questioned, and in doing so explains how the child receives from the mother immunity from syphilis and other infectious diseases.

"To return to the investigations which I have been pursuing, I may say that I have not, in my line of practical work, followed out any one theoretical path. I have instituted micro-organic war. Thus I have pitted one kind of micro organism against another.

"I have dissolved germicides in predigested fat and added small quantities of bile, and injected it into the intestinal tract. My object in this was first to stimulate the glands to work, and at one and the same time bring the germicide, as nearly as possible in its nascent state into contact with the glands. The addition of the bile was with the idea of assisting absorption.

"I have also conceived a method of injecting germicides into the spleen with the object of reaching the blood corpuscles, when in a state of transition, with the chemical in an unchanged condition, and I am investigating the plan of passing virus through different animals for the purpose of finding conditions that would lessen the degree of virulence.

"Then again, I have produced tuberculosis in the skin of animals, thereby exposing the germ to a greater supply of oxygen and light than when growing in the viscera.

"Other methods are to attenuate preparations of the products of the tubercle bacillis growing on nutritive mediums, and inject them into the intestinal tract.

"The hypotheses advanced in my terse article in the *Medical News*, of October, 1889, have given the most brilliant results. Yet, I have never felt that the time had arrived for me to experiment on the human subject. Nor do I mean to be tempted to take any risks until the act would be purely an unselfish one. Even with the results that have been obtained in my laboratory, *I would be sorry to have the general public stimulated with the idea that inoculation for tubercular phthisis has been perfected.*

"Owing to the rumored report that Prof. Koch has been, and is inoculating human beings, it behooves me to await his results and understand his methods. Should his prove to be similar to my own, I will at once inoculate man.

"If, however, it should appear that he is working on different lines, and that his plan is less dangerous than my own, it will be welcomed and adopted by me."

Annotations.

THE Medico-Chirurgical Hospital, of Philadelphia, has always prided itself upon the truly charitable work done by it, and its freedom from those troublesome restrictions that sometimes hinder other institutions from extending aid to needy cases. An incident that occurred in New York November 5, fully illustrates the importance of this point. A driver fell from his seat and was run over, having both legs broken. An ambulance was summoned, but the surgeon in charge said he could not take the man to Roosevelt, as it was a case for Bellevue. The charity ambulance came next, but "the case was out of his district," and his hospital only "took cases of insanity and alcoholism." After the man had lain on the pavement for two hours and thirty-five minutes, he was at last taken away.

ENCOURAGE HOME SCIENCE.

WHEN we read of the encouragement Koch is receiving from the German government, of the clinical material, laboratory facilities, and funds placed in profusion at his disposal, we are constrained to admit that there are elements of value in the paternal style of government. Nobody grudges the little bit of the taxes that goes to such a purpose. But here, where everything is left to individual exertion, too often it is seen that what is everybody's business is assumed by nobody. The importance to humanity of such investigations as Dixon's cannot be overestimated. Not all the wars, nor all the pestilences, "since first the leaky ark reposed in mud," have destroyed a tithe of the lives that have fallen victims to the tubercle bacillus. Not a home exists but has put on mourning for some loved one dying from consumption. And yet not an effort is made to put our own countryman on an equality with the European investigators, as regards facilities for this work.

SIR MORELL MACKENZIE objects to large hospitals, on the ground that they are an unscientific anachronism; the aggregation of the sick in large numbers being as much out of place as intramural interment. The added virulence of germs from the bodies of numerous cases is to be considered more dangerous than that of those emanating from dead bodies.

Another objection to the large hospital is that the relief given by it is in a sense indiscriminate. The out patient department of hospitals is the greatest pauperizing agency now existent. From this comes the third objection—the cruel hardships entailed upon medical men in the neighborhood. He considers the special hospital in a large degree free from these and other objections, and favors the exaction of a small fee from dispensary patients.

While this would not in any degree relieve the neighboring practitioners, or obviate any of the above objections, as the fee must perforce be a level one and within the means of the poorest, it would greatly benefit the hospital exchequer. It may be safely said that in our goodly city of brotherly hatred there are none too poor to afford an occasional glass of beer. If a charge of five cents were made for every prescription filled, the aggregate would constitute a handsome sum. If the fee required were larger, there would be a serious diminution in the number of patients applying, unless all the large clinics were to unite in making a uniform charge.

Letters to the Editor.

I AM requested by the Hon. Secretaries of the Committee of Organization of the Seventh International Congress of Hygiene and Demography, to call attention to the fact that this Congess will be held in London during the week beginning August 10, 1891.

The governments of all countries and municipalities, and all public health authorities, universities, colleges and societies occupied in the study of the sciences more or less immediately connected with hygiene, are invited to coöperate and appoint delegates to represent them at the Congres. The Prince of Wales will preside.

A committee of organization has been formed, of which Sir Douglas Galton is Chairman, and Prof. W. H. Corfield and Mr. Shirley F. Murphy are Honorary Secretaries. An exhibition of articles of hygienic interest will be held in connection with the Congress. The last of these Congresses was held in Vienna in 1887, and was attended by over 2,000 persons, and it is expected that the London meeting will be one of great magnitude and importance.

JOHN S. BILLINGS, M.D.
Member of the International Permanent Committee.

Book Notices.

THE PHARMACOLOGY OF THE NEWER MATERIA MEDICA. Part VII. Embracing data upon Chian, Turpentine, Damiana and Jamaica Dogwood. Geo. S. Davis, Detroit.

ESSENTIALS OF MINOR SURGERY AND BANDAGING, with an appendix on venereal diseases. By EDWARD MARTIN, A.M., M.D. Illustrated. W. B. Saunders, Philadelphia, 1890.

VIVISECTION. By ALBERT LEFFINGWELL, M.D. New York: Jno. W. Lovell Co. Paper, pp. 95. Price, 20 cents.

The author advocates the restriction of vivisections, to the exclusion of experiments intended to illustrate physiological points already established.

A COMPEND OF HUMAN ANATOMY. By SAM'L O. L. POTTER, M.A., M.D. Fifth Edition, revised and enlarged, with 117 wood engravings, and appendix, and 16 lithographic plates of the Nerves and Arteries. Philadelphia, P. Blakiston, Son & Co., 1890.

Dr. Potter's compend has proved so popular that a fifth edition has been called for in three years. We do not know that we need say anything else about the book. The profession evidently stands ready to buy it.

MATERIA MEDICA FOR NURSES. Compiled by LAVINIA L. DOCK. G. P. Putnam's Sons, N. Y., 1890.

This is intended to serve as a text-book for nurses' schools. It contains much information that will prove useful to nurses, and a good deal that they can have no possible use for. The arrangement is bad, the division into inorganic and organic, with appropriate subdivisions, being of no value to any one. The matter in each topic is, however, pretty well selected.

BACTERIOLOGICAL TECHNOLOGY FOR PHYSICIANS, with seventy-two figures in the text. By DR. C. J. SALOMONSEN. Authorized translation from the second revised Danish edition. By William Trelease. New York: Wm. Wood & Company, 1890.

The objects of the author are stated to have been the preparation of an outline adapted to bacteriological courses for physicians and veterinary surgeons, and a guide for home study without an instructor. The simplest and easiest apparatus and methods are described; such as require an inexpensive outfit. For the practitioner's use, this book is well fitted, as containing what he can readily utilize, leaving more extensive works to those who make such studies their special work.

A MANUAL OF AUSCULTATION AND PERCUSSION. Embracing the Physical Diagnosis of the Lungs and Heart, and of Thoracic Aneurism. By AUSTIN FLINT, M.D., L.L.D. Fifth Edition; thoroughly revised. By J. C. Wilson, M.D. Illustrated with wood cuts. Lea Brothers & Co., 1890. Cloth, 12 mo., pp. 268. Price, $1.75.

Dr. Austin Flint was a master of this art, and had the rare faculty of expressing himself clearly in few words. The present edition has assuredly suffered nothing by the editorship of Dr. Wilson.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS. By S. W. GROSS, A.M., M.D., L.L.D. Fourth Edition; revised by F. R. Sturgis, M.D. Philadelphia: Lea Brothers & Co., 1890. 8 vo., pp. 173. Cloth. Price, $1.50.

The name of the younger Gross will long be remembered from his work on the mammary gland, and the book before us. On its first appearance the present work was acknowledged to be the best on the subject then extant, and no subsequent work has deprived this one of its supremacy. The neglect of this group of diseases by the regular practitioner gives one of his most fruitful fields to the quack.

REGISTER OF PHYSICIANS IN PENNSYLVANIA BY COUNTIES, from July 1, 1881, to December 1, 1888. Taken from the Fourth Annual Report of the State Board of Health. Harrisburg, E. K. Meyers, State Printer, 1890.

It is greatly to be regretted that this register is incomplete; thirteen counties having failed to make returns. Indeed, scarcely any of the data was supplied by the county authorities, but was collected by the efforts of Dr. Lee.

Out of the report we gather that there are over 9,000 physicians in the State, or one to every 459 inhabitants, by the census of 1880. In some counties the law has been ignored; but two registrations having been made in Bedford and twelve in Lehigh. Of the 8,248 reported, 641 are of foreign birth; 384 of these coming from Great Britian and her dependencies, and 165 from the German empire. Out of 76 names on the first page, 8 are said to be illegally registered.

ANNUAL OF THE UNIVERSAL MEDICAL SCIENCES. A yearly report of the progress of the general sanitary sciences throughout the world. Edited by CHARLES E. SAJOUS, M.D., and seventy associate editors, assisted by over two hundred corresponding editors, collaborators and correspondents. Illustrated with chromo-lithographs, engavings and maps. F. A. Davis, publisher. Philadelphia, 1890.

The third years' Annual will serve to keep alive the memory of La Grippe; as the editor states in his preface that the work was greatly hindered by the prostration of more than half the staff by that troublesome affection. No trace, however, is to be found in the pages of the five handsome volumes, of the debilitating influences of the great epidemic. On the contrary, the edition of 1890 is fully up to the standard of previous years. In a work of such magnitude it is inevitable that there should be inequalities. Good judgment in selection and skill in condensing are not so generally possessed by even highly educated physicians as to make all parts of such a work of the highest merit. But a careful examination of the Annual induces surprise at the general excellence of the whole work. It would be invidious to criticise the few lapses noted. Much valuable matter has been necessarily omitted, to keep the work in proper limits; and in some cases individual favor appears to have been consulted in the selection rather than merit. But this is inevitable, until the dawn of the millenium or the general

adoption of the Bellamy system inaugurates a new race of men, superior to ignoble influences. In the meantime, the Annual is a work of such value that we cannot see how a practising physician can do without it. It is a medical library and reading-room of exceptional comprehensiveness.

OINTMENTS AND OLEATES, ESPECIALLY IN DISEASES OF THE SKIN. By JOHN V. SHOEMAKER, A.M., M.D., Second Edition. Revised and enlarged. Philadelphia: F. A. Davis, Publisher, 1890. Price, $1.50.

In spite of the paltry attempt of the editors of the last edition of the U. S. Dispensatory, to ignore Dr. Shoemaker's work, his name will be associated with the oleates as long as they are employed in medicine. Although Dr. Shoemaker was not the first to employ the oleates, nor, we believe, has he ever claimed priority in their use, it was he who directed the attention of the profession to these therapeutic agents and gave them the wide popularity they now enjoy. The present edition gives the result of five years' additional experience on the author's part. In addition, he has extended the scope of the work by including a consideration of ointments in general; including those in use here and in the leading countries of Europe.

We regret that in the well-written chapter on ointment bases, no mention is made of mollin or of oleite, both which are important when the absorbability of drugs from ointments is considered. The numerous prescriptions are in English; and between this and bad Latin the choice is easily made. But as long as we have a Pharmacopœia the better way is to follow it, for the sake of uniformity. The substitution of *official* for officinal is objectionable on the same score. The European formulas serve to show how far their pharmacists are behind our own. Some of their ointments are fearfully and wonderfully made; as, for instance, the following, known as "Noah's Ointment:"

℞.—Basilicon ointment,
Althea "
Laurel "
Mercurial "
Poplar "
Oil of hypericum,
Myrrh,
Petroleum,
Oil of lavender,
Oil of turpentine, of each, equal parts.

In a former number we have given examples of greater value. The author does not take an enthusiastic view of the oleates, but claims for them a "prominent place among the more scientific means for treating" diseases of the skin.

The reader will find many good things in the book; enough to pay him many times over for its cost; in fact, it is one of the works which will not idly occupy its place on the owner's shelves, but will soon be ornamented with frayed edges, dog's ears, and other evidences of use, by an appreciative owner.

The Medical Digest.

IN spite of all efforts, fevers are rapidly spreading in London.

PEROXIDE OF HYDROGEN is said to quickly relieve pruritus vulvæ.

TO relieve pain by hypnotism, and thereby render the patients hysterical, is to cast out Satan by Beelzebub.—*Germain Sée.*

HANNON, (*Med. News*) details two cases of vesical calculus, in the successful treatment of which, Buffalo Lithia Water was a prominent factor.

NOCARD finds that strychnine does not hinder the development of tetanus in animals after injections of tetanus poison have been given, as Peyraud claimed.

BOKAI reports two cases of scarlatina in which the incubation did not exceed sixteen hours. The children were admitted to the hospital for diphtheria, and in sixteen hours the scarlet eruption appeared.

SALOL IN CHOLERA.—Macrae, in the *Indian Medical Gazette*, records his experience with salol in twenty-five cases of cholera. The mortality was 60 per cent., and the author considers the drug a failure, unless as a prophylactic and in the very early stages.

FOR EXCESSIVE VESICAL TENESMUS.—

℞.—Benzoic acid	. . . . .	4 parts.
Borax	. . . . .	6 "
Water	. . . . .	180 "

M.—S. Three tablespoonfuls a day.

—*Med. Press.*

DIGITALIS.—The indication for the use of digitalis is not a murmur in the heart, nor a certain form of valvular lesion, nor tumultuous action, nor yet rapidity of action, but whenever it is desirable to fill the arteries and empty the veins.

—Dewees, *Kansas Med. Jour.*

MCSHERRY'S GARGLE.—

℞.—Zinci sulphat.		
Acid. carbolici	. . . . .	āā gr. v.
Glycerini	. . . . .	℥ss
Aquæ	. . . . .	℥iijss.

M.—S. Use as gargle, three or four times a day.

—*Baltimore M. and S. Record.*

A SEDATIVE FOR BABES.—

℞.—Camphoræ monobrom.	. . . . .	gr. j. ij
Ext. hyoscyami fl.	. . . . .	gtt. v. viij.
Syr. lactucarii	. . . . .	℥ij.

Tere optime, fiat mistura.

S. A teaspoonful as needed.

—*Ex.*

TORSION OF ARTERIES.—Murdoch (*Weekly Medical Review*) speaks as follows of torsion: The advantages of torsion as compared with ligation are: 1. The greater facility with which it can be applied. 2. Torsion is a safer method, being less liable to be followed by secondary hemorrhage. 3. Healing is facilitated, because the wound is free from any irritating or foreign body.

TOBACCO IN HERNIA.—Spalding (*Texas Courier-Record*) describes a case of acute inguinal hernia in a man thirty years old. Chloroform and taxis, with inversion, failed to effect reduction. A strong decoction of tobacco was injected into the rectum. In fifty minutes there was great prostration, feeble pulse, retching, and full tobacco narcosis. Examination then showed that the hernia had disappeared.

PILOCARPINE IN DERMATOLOGY.—Klotz, in the *Journal of Cutaneous and Genito-urinary Diseases*, describes two cases in which pilocarpine proved useful. The first was a case of squamous eczema, with dry, hard, resistant, slightly scaling skin. Injections of pilocarpine were employed with much benefit. The other patient had eczema squamum and

rimosum of both palms, which were covered with a very hard and thick horny skin. Little progress was made towards a cure until the pilocarpine injections were used.

The author's conclusion was that the use of pilocarpine in pachydermatous and xerodermatous conditions of the skin is strongly indicated, and deserves to be subjected to renewed trials, but in small doses and long continued, as recommended by Pick.

EHRLICH'S TEST FOR TYPHOID FEVER.—Make two solutions, one consisting of 72 minims hydrochloric acid and 10 grains sulphanilic acid in 3 ounces distilled water; the other, a freshly-prepared ½ per cent. solution of sodic nitrite in distilled water. To 26 parts of urine from a typhoid fever patient, add 25 parts solution 1, and 1 part of solution 2, and the mixture is rendered alkaline by addition of ammonia. A bright orange-red color appears.

SALOL IN TYPHOID FEVER.—Whatever the differences of opinion as to the cause of typhoid fever it is pretty definitely settled that, after a certain stage, the disease is a septicæmia, due to the ulceration of Peyer's glands. The natural tendency of the fever is to terminate about either the fourteenth or the twenty-first day, and when an intestinal antiseptic, such as salol, is used, which prevents the ulceration from infecting the system, the natural tendency to recovery is increased.—Cahall, *Med. News.*

KANSAS FERTILITY.—The wife of John Bean, of Valley Falls, aged sixty-five years, gave birth to twins on Monday evening. Her daughter, Mrs. Stratton, who lives in a neighboring township, presented her husband with twins the same evening. Mrs. Stratton's daughter Eva was married a year ago and lives in Arrington. The friends were not yet through congratulating them when Mrs. Stratton heard that her daughter had given birth to twins herself on Monday evening. The three double births occurred within ten minutes of each other.

—*Kansas Med. Jour.*

RIDER'S BONE.—Schmit gives, in *Revue de Chirurgie*, a review of this subject. The name is given to an osteoma developing in the muscles of the thigh in horsemen. In one of his two cases the affection was bilateral. It has been found in the adductors, pectineus, gracilis, biceps, and psoas; and occurs almost constantly in cavalry soldiers, being developed in the early days of their training. It is due to injury, and develops in two to sixteen weeks. Once formed, it does not enlarge. It interferes in variable degree with duty, and is easily and successfully removed.

—*Brit. Med. Jour.*

WOUNDS OF THE LUNG.—It seems to the writer that we have, in the case of gun-shot wounds of the lung, a condition closely analogous to similar wounds of the abdomen; we have the same dangers to meet and overcome, modified merely by peculiarity; our means of meeting these dangers are more direct in the case of the abdominal wound than in the pulmonary, but, nevertheless, we have such means in the free incision and drainage as above proposed; therefore we are, from a surgical standpoint, justified in employing this procedure, and it is the firm belief of the writer that, if used, we may look forward hopefully to the result, and that the prognosis in such cases will be much bettered thereby.

—Axford, *Med. Standard.*

ANALGESIA is a frequent symptom in insanity, and its importance is largely due to the fact that its presence is a menace to the physical well-being of the patient. Its etiology and pathology being yet but little understood, it is certainly worthy of more extended and careful study. As, apart from paresis, epilepsy, and in a lesser degree in dementia, its presence cannot be predicted in any case, but must be sought for; and as further it is not incompatible with comparatively high grades of intelligence, it is well to look for it in every case. And, finally, if it proves to be at all frequent in the early stages of alienation, a new and valuable aid to diagnosis will be at our command.—Keniston, *Amer. Jour. of Insanity.*

MAGRUDER, in *Practice*, reports the removal of a large vesical calculus per vaginam. The stone was immovable, the bladder appearing as if contracted around it. A pair of tooth forceps was employed to break up the concretion, and detritus washed out with a fountain syringe. The stone filled up the pelvis as a fœtal head would, and a vesico-vaginal opening had been produced, which was utilized in the operation. The patient made a good recovery.

TOWNSEND (*Archives of Pediatrics*), employed bismuth, sodium salicylate, lactic acid, and resorcin in summer complaint; the result being expressed in the following words: "I am inclined to be rather skeptical as to the value of these antiseptics in the treatment of summer diarrhœa." Lavage of the large intestine with tepid water gave better results, ten out of thirteen cases showing marked improvement.

ARISTOL.—I have drawn the following conclusions, after observing its action during the past five months:

1. The drug is free from all objectionable odors.
2. When used over large surfaces, you obtain all of its medicinal effects without any toxic effect. It is not absorbed.
3. It possesses stimulating, alterative, and anæsthetic properties; the latter effect less marked than that obtained from iodoform.
4. It does not produce any discoloration of the skin.
5. On account of its dark color, you can readily observe how far the powder has been used on a diseased surface.
6. It is not irritating, and its use is not contra-indicated in the treatment of facial eruptions, as chrysarobin and pyrogallic acid.
7. It appears to possess the necessary properties to make it an efficient substitute for iodoform.

—McLaughlin, *Va. Med. Monthly.*

CHRONIC, SO CALLED RHEUMATIC AFFECTIONS.—When the term chronic rheumatism is used, it should be limited to those cases in which the joints are painful but not swollen, or in which there is a neuralgia or an arthralgia associated with myalgia or apart from it; or in which the fasciæ are affected, or in which there is a general neuralgic condition supervening on an acute attack of rheumatism. This is what we prefer to call "chronic rheumatism." But in speaking of the symptoms of rheumatoid arthritis, I will make reference to those symptoms which are sometimes put down as common to both. Let us imagine two patients sitting side by side, one with chronic rheumatism and the other with rheumatoid arthritis. Now, what do we see? In the rheumatoid arthritis case the first thing that strikes us is most probably the pallor of the patient, as compared with the chronic rheumatic. We look a little closer, and the

next thing we perceive will most probably be the joints. The patient with the chronic rheumatism will present in this feature little or nothing; whereas, on the other hand, the rheumatoid arthritis patient will be more or less crippled. There will be distinct muscular atrophy in the rheumatoid arthritis case, and the complexion will present the pallor mentioned before, showing on closer inspection yellowish tinges on the face, neck, and perhaps elsewhere. If we ask both patients if they ever had rheumatic fever, they will probably say No; but further inquiry will elicit the probable fact that the family history of the patient with rheumatism will be a good one, or perhaps at the most a rheumatic one, while the rheumatoid arthritis patient in most cases gives or shows a strumous taint. It is upon the basis of this strumous taint that we feel we must look for further assistance to guide us in the treatment of this terrible crippling malady. It is nearly always present more or less. We are aware that this strumous history has not been particularly referred to in other descriptions of the disease. It being the almost invariable accompaniment has induced us to bring the matter forward. In fact, to look upon struma and rheumatoid arthritis as cause and effect, has seemed to us the one plain characteristic in our investigations.—Lane, *The Lancet.*

Exercise in Pelvic Diseases of Women.—Kellogg, in the *Medical News*, thus advertises his sanitarium:

The propositions which I shall undertake to maintain in this paper are the following:

1. That defective muscular development is a prime factor in the etiology of a large number of the pelvic disorders to which civilized women are subject.

2. That the mode of dress common among civilized women is a cause of deficient and asymmetrical muscular development.

3. That the dress commonly worn by civilized women is productive of such disturbances of the relations and functions of the abdominal and pelvic viscera as directly lead to the production of functional and structural changes in the uterus and its appendages.

4. That properly-graduated exercises, with adjustment of the clothing that will permit free and unrestricted movements of every group of muscles in the body, are of great importance in the management of a large class of pelvic disorders.

For Neurotic Incontinence of Feces.—Take of:

Strychnine crystals	gr. xvj.
Acetic acid, dilute	ʒiv.
Alcohol	ʒiv.
Tr. cardamom comp	ʒj.
Water to make	ʒxvj.

M.—S. Take ten to twenty minims with an equal amount of fl. ext. ergot after each meal.

Before retiring I had him cleanse the lower bowels with a hot decoction of hydrastis canadensis. The strychnine was given as a nerve tonic; the ergot was for tone to the circular muscles; the heat as a stimulant to the bowels; the hydrastis as a tonic and healing agent to any catarrhal or ulcerated condition which might be present, and the water as a vehicle and cleansing agent. The results of four months' treatment are that when the patient is careful of his diet he has but one movement of the bowels every twenty-four hours, and that at the time of the injection of the decoction of the hydrastis. He says if he guards his diet and cares for his treatment as directed, he never has more than one action per day.

—Mendenhall, *Med. Standard.*

Marriageable Age of Females in India.—In a discussion on this subject at the Calcutta Medical Society (*Indian Medical Gazette*), Mrs. Foggo presented a report, from which we take the following: "In no other country have I seen as many cases of derangements of the generative organs as since I have had charge of the Lady Dufferin Zenana Hospital—infantile uterus, absence of ovaries or uterus, or both—and, after strict inquiry, I feel myself justified in putting it down to pre-menstrual copulation." Her conclusion was that the marriageable age for females in India should be fixed at fourteen years.

Bolye Chunder Sen claimed that the prevalent belief concerning early puberty in India was erroneous, except where precocity was induced by child-marriage and early sexual excitement. In the Brahmo community, he found that out of 65 girls, 2 menstruated before the twelfth year, 3 during the twelfth, 29 during the thirteenth, 26 during the fourteenth, 4 during the fifteenth, and 1 during the sixteenth year. It was also a fact that the eruption of the teeth occurred somewhat later than in England. He advocated sixteen years as the minimum age for the consummation of marriage.

The Cincinnati *Lancet-Clinic* makes the following comment on Dr. Bartholow's retirement:

"Notwithstanding the slack of tension, some months ago tidings were borne to us of erratic conduct that passed beyond the bounds of eccentricity and clearly indicated symptoms of an unsettled mental equilibrium. The weakest link was sagging.

"A sense of sorrow for the surely coming wreck locked 'the news' from the public. We felt that a giant intellect was tottering, an intellect that had given its very life to scientific and clinical research was dying, its light was becoming a shadow; until, at last, the public have 'the news.'

"A pall of mournful sadness comes over us as we contemplate the thought of this termination of such a career as that of the indomitable, the gifted Dr. Roberts Bartholow.

"A lesson, a parting lesson, is hereby taught, and should be thoroughly heeded by those who feel the iron grip of an insatiable ambition that is inordinate in its character, that leads and goads the discontented to a violation of physiological laws in order to be able to accomplish some specific purpose that may be ever so laudable in motive. To some we say: Slow up, lest a link be weakened and the golden bowl broken."

Total Blindness Following Shock—Recovery.—November 18, 1889, I was called to see a boy of six years, who had become blind the day before. The boy had been exceptionally rugged and active. October 23 he had had a transient attack of headache and vomiting. November 4 he had a transient attack of what seemed to be a cold, accompanied by wandering rheumatic pains in the feet and limbs. November 12 a mild tonsillitis with a temperature of 101°. November 14 the mother fell down stairs; the boy was greatly frightened, and was soon seized with a severe headache followed by epistaxis and relief. Light diet had been ordered, but on the 16th he was so well and so hungry that he was allowed to eat a large piece of beef-steak for supper. The following day he had a convulsion followed by total blindness.

Status præsens, November 18—nervous and restless, but does not complain of pain. Answers questions slowly, but intelligently. Sensibility is

much diminished in the extremities. The pupils are moderately dilated, and both react slightly to light, but the left less than the right. The ophthalmoscope shows no changes at the fundus. Small doses of calomel and iodide of potassium were ordered. November 20, vision began to return, and two days later was fairly good. December 3, there is some anæsthesia of the hands and feet as well as diminished control of them. The arms and legs are considerably shrunken, and at times there are pains in the latter. The right pupil reacts sluggishly to light. Vision is good, and the fundus normal in both eyes. There is headache at times, but the boy eats and sleeps well, and is steadily improving.

At the present time Dr. Murray reports the boy as entirely recovered.—Brown, *N. W. Lancet.*

Acute Epiphysitis.—In March, 1890, a youth, aged fourteen, was supposed to have had an attack of acute rheumatism. He came under my care three weeks after its onset, with the usual signs of acute synovitis of the hip, very ill, and with a temperature of 101°. A few days afterwards some pus was removed with an aspirator from the neighborhood of the hip. For a day or two afterwards the local condition improved, but in the meanwhile it had been ascertained by cultures that the pus contained staphylococcus aureus. The temperature continued high (101.8°), and the boy was losing ground so rapidly that the hip-joint was explored by an anterior incision. There was pus both within and without the joint, and the upper epiphysis of the femur was only joined to the shaft by some soft inflammatory material, which was afterwards found to contain micrococci; the ligamentum teres and the acetabular cartilage were intact; but the articular cartilage of the femur had partly disappeared without any caries of the bone. The head of the femur was removed, and the wound drained and treated in the usual way. The dressing was renewed on the fifth, ninth, and fourteenth day, and then replaced with a dry dressing, under which the wound healed within six weeks after operation.—Lockwood, *Brit. Med. Jour.*

Piscidia Erythemia.—It can be used in many troubles, chief among which is neuralgia, facial, cardiac, gastric, or ovarian. In the ovarian and cardiac types it seems to be particularly efficacious. In pain about the heart, associated with rheumatism, it is reliable. In ovarian neuralgia and neuralgic dysmenorrhœa it has worked wonders, relieving pain and having little or no effect upon the bowels. In some cases of bowel trouble, characterized by retained indigestible matter, extreme pain, and nervousness, a dose of fifteen drops of the piscidia extract has quieted pain and nervousness, and at the same time interfered in no wise with the expulsion of the disturbing element. In cystitis it has been a sovereign remedy, controlling the tension and severe burning pain in short order. In incontinence of urine it has been happy in its effects. Many reflex coughs are dissipated by its exhibition. In the intense nervousness and distress shown by men on the verge of delirium tremens it has done remarkably good work. I have used it in half-drachm and drachm doses, and induced quiet and restful sleep. Whenever an intolerance to opium is shown, there seems to be an unusually good field for the exhibition of piscidia.

I have as a rule used it in doses of from five to ten drops, very seldom exceeding that. I have seen several cases in which eight drops, repeated once in three hours, caused most alarming symptoms, such as heart failure, cold skin, dyspepsia, inability to swallow, and a bluish condition of face, lips, and finger tips. It should be used most cautiously, and the dose increased as you obtain an idea of the patient's ability to stand the drug.

—Pitcher, *Detroit Emerg. Hosp. Reports.*

Excretal Dermatitis.—Walsh, in the *Medical Press*, thus summarizes a paper on this subject. His propositions are:

1. That dermatitis may be set up in a certain number of cases by the excretion of irritant products from the system.

2. That such irritants may be either chemical or due to specific micro-organisms and their products.

3. That many of the inflammations of the hypoblastic as well as of the epiblastic tissues are simply expressions of excretory irritation.

4. That the severity of the inflammation, and consequent damage, is in proportion to the specific effect of the irritant upon excretory epithelium.

5. That excretory parallels may be drawn between drugs and specific disease-poisons, both as regards their channels of elimination and their harmfulness to epithelium.

6. That while excretion affords the key to a certain number of skin inflammations, it also accounts for the success of many well established methods of treatment which aim at shifting the channels of elimination. At the same time it affords a rational basis for further therapeutic measures.

7. Finally, some observers trace the tendency to catarrhal troubles—the "eczematous condition"—to an unstable epithelium. Others refer them to disorders of the nervous system, such as trophoneuroses. While freely admitting there are wide differences of predisposition in individual skins, yet it seems probable that the dermatitis is not infrequently an excretionary symptom secondary to a blood condition.

Galvano-Cautery in Corneal Diseases.—A few minutes after the instillation of a few drops of a 5 per cent. solution of cocaine, there is complete anæsthesia of the corneal layers, so that the approach of the red-hot loop, or its repeated application (which is usually accompanied by considerable hissing and sizzing) causes no painful sensation.

The operator separates the lids, and applies the heated loop to the infected zone, making and breaking the current by the simple pressure of a button on the handle of the electrode.

In a short time we observe a surprising change. The adjacent corneal tissue gains increased transparency. The turbid aqueous becomes clearer. The trifling pain following the operation soon ceases. If there is hypopyon it is speedily absorbed. The zone of infiltration rapidly recedes and fades. And in many cases within the next twenty-four hours such an improvement will be manifested as to show the destructive process to be at an end, and the process of repair already begun. However, if after twenty-four hours the ulcer shows a tendency to extend, a similar "touching" should be again resorted to.

The loop should be applied until the masses of detritus clinging to the floor and sides of the ulcer are destroyed. The bordering infiltration for a short distance should also be destroyed; none of this parasitic material should be allowed to remain; it should be completely sterilized. If this be done a recurrence need not be feared, for it is a fact now universally admitted, that the development of spores becomes impossible on sterilized soil.

The treatment by the galvano-cautery, as outlined, secures benefit to the tissues in a threefold way:

1. It separates rapidly and thoroughly the parts already involved from the yet healthy tissue.

2. It averts the extension of the infection, and makes the adjacent tissues aseptic.

3. It stimulates the tissues to take on a healthy reparative process.

Especially applicable is the galvano-cautery in the treatment of rodent ulcers, in which every new point of infection demands its prompt destruction. Here we require a white-hot tip sufficiently delicate to allow of the nice manipulation necessary for working in a district of no more than a millimeter in extent. And this is only possible with the galvano-caustic loop, which is brought to a red heat at the exact moment when it was needed, and cools as quickly, and produces no annoying light effects by the glowing of the wire.

It is also highly serviceable in scrofulous ulcers of the cornea, which show a deep crater-shaped excavation, with sharply cut edges, accompanied by a light grade of ciliary irritation and muco-purulent conjunctival secretion, and which defy all therapeutic agencies.

It is applicable also in those ulcers due to the entrance of foreign bodies.

And, lastly, in the chronic indolent ulcer, painless and apparently lifeless, showing no tendency towards a reparative process, the galvano-cautery is an efficient agent to stimulate and bring about a healing process.—Magee, *Kansas Med. Jour.*

Changing Pessaries.—As far as I am aware, no change whatever is made in the size of a pessary worn during the time occupied in the treatment of a case of chronic retroflexion or retroversion. Nor are there any directions given in the latest text-books on the subject of gynecology to this end. As a rule, a pessary—when found to fit and give relief to the most marked symptoms of discomfort of which the patient may complain—is allowed to remain without change for a considerable period, and when removed, either for facility of examination or for cleansing, is almost directly replaced should the flexion or version for which it was originally introduced be still found to exist (though it is to be hoped in not so marked a degree). I consider that the ground gained by the wearing of a properly-fitting and well-adjusted "Hodge," is not fully taken advantage of *unless another slightly longer is substituted for the one worn, at regular intervals*, till a degree of ante-version is obtained, so that when eventually the pessary is finally removed, there will be far less likelihood of any return of the uterus to its original abnormal position. Again, the length of time occupied in the treatment of such cases will be considerably shortened by the change of the pessary.

The very important point of endeavoring to replace the uterus as nearly as possible in its normal position *before introducing a pessary* is often overlooked. The knee-elbow position will be found the best, either for manipulation or the introduction or removal of the pessary, unless contra-indicated by some pectoral or cardiac lesion.

The practical advantages I have found by adopting this plan must be my excuse for publishing this paper.—Duke, *Med. Press.*

Diphtheria from Animals.—I found out the following practical cases, pointing to the direct infection of children from hens affected with diphtheria:

1. In Corrientes street, a child, two years of age, died in the month of January. The house had a single story, and had a back yard without pavement. A few days before the child took ill two of the hens which were kept in the house had ulcers in the throat.

2. In California street, two children, one two years old, the other four, died in the month of March. The house was a lodging-house, and had a back yard without pavement. A few days before the children died two of the hens which were kept in the house died, having "made a strange noise with their throats" during their illness.

3. In Europe street, a child, three years of age, died in the month of April. Lodging house, with back yard, without pavement. A month before the child died the hens sickened with an "affection of the mouth."

4. In Salta street, a child, nine years old, died in the month of April. House had a back yard, without pavement. Three weeks before the child, several of the hens died with "ulcers in the throat."

5. In Talcahuano street, a child died from diphtheria (all these cases that I am relating died from this disease). This child was in the habit of playing all day in the back yard, where the hens were kept. In those days when the child sickened, several hens died from an affection, where the "throat was swollen, and membranes were extracted from the nostrils."

6. In Jehallos street, two children died of diphtheria in the month of May. Back yard without pavement. A month previous to the death of these children the hens suffered from ulcers in the throat.

7. In Belgrano street, a girl, sixteen years of age, died of diphtheria. The yard was paved, but imperfectly so. A hen house was kept in the yard. A few days before the girl died two of the hens had suffered from ulcers in the throat.

8. In San Antonio street there is a large lodging-house, where several children had died of diphtheria at different times. There is a yard without pavement. The man in charge of this house informed me that it is a common thing for the hens kept there to suffer from ulcers in the throat.

9. A physician in Buenos Ayres lives in a two-story house. On the ground floor a hen house is kept on one of the "patios." One day he saw one of his children playing amongst the hens, and, reminding that he had once assisted at a fatal case contracted from a diphtherial hen, he called out to his child to come upstairs. Next day the child sickened with diphtheria, and subsequently died. It was found that the hens at the time were suffering from ulcers in the throat.

These cases which I have selected would of themselves point strongly to the direct infection of children from hens and other animals; but, taken in conjunction with recent observations made in England and on the Continent, they are a strong testimony to the truth of the theory which ascribes diphtheria in animals to the presence of a damp soil, and diphtheria in the human subject to contagion from animals so infected. I do not for a moment wish to state that diphtheria in the human subject has no other origin than that just mentioned. It is, however, ascertained that diphtheria in the human subject may be due to dampness, to the removal of mixed deposits of vegetable and animal matter after they have been in intimate union for some time, to infected milk, and lastly, but very rarely, to infected water.

Davison, *Brit. Med. Jour.*

CONCERNING POSSIBLE THERAPEUTIC USES OF HYPNOTISM.—I am not very sanguine as to the future of hypnotism as a curative agent in nervous or other diseases. According to my own researches—and those researches date back eight years or more—the method is vastly more limited than one would imagine from the exaggerated claims which have been of late advanced in its behalf by over-zealous medical men. Let me mention a few of those limitations. In the first place, only a certain (unknown) percentage of persons are amenable to the hypnotic influences, or, to express it more exactly, only a limited number of persons are hypnotizable with the present means at our command. Secondly, the effects obtainable are evanescent; for, unless we hypnotize the patient so often as to incur the risk of doing him an injury, we cannot hope to perpetuate the suggestions sufficiently to do any good.

From these considerations it follows that the permanent effects which one may hope to produce upon the material economy through this class of psychical forces must be insignificant. Functions may, it is true, be exalted or depressed for the time being, but qualitative changes in the structures themselves are impossible. The internal capsule, the thalamus, the motor convolutions, the sensory tracts in the cord once destroyed, are not to be restored by any form of interference. Moreover, a physiological substitution (in Bernheim's sense) for these and analogous structures, seems well beyond the farthest bounds of physiological probability. Hence, as I have previously mentioned, all attempts to apply hypnotism to the treatment of organic disease are opposed to sound thinking. Indeed, I regard such proposals as hurtful to science, and particularly medical science, inasmuch as the reputation of the profession for sound judgment is thereby greatly jeopardized. The facts which the advocates of such questionable methods have to present are still too few in number, and too meagrely substantiated, to form the basis of affirmative argument. What then is the position which hypnotism may be expected to assume in the neuro therapy of the future? In my opinion the rôle which it is destined to play is a subordinate one. In the light of its present and past history, I do not see how it can be otherwise. As an adjunct in the management of minor degrees of hypochondria, morbid apprehension, depression, and hysteria, it may sometimes be invoked, but then only as a collateral expedient, and largely with a view to rendering the patient more tractable and amenable to other elements in the plan of treatment. The aid afforded by an appeal to the expectancy of the sick is familiar to every physician; by invoking the aid of the hypnotic state such an appeal may be made with an energy which is not attainable while the patient remains in the ordinary mental condition. But, while the miracles recorded by enthusiastic writers make, like Munchausen's tales, entertaining reading, they are not likely to enter into the sober realities of the consulting room.

In view of what we now know of it, hypnotism is to be dealt with by the physician; for it is evident that a competent medical man is alone in a position to judge of its real or imaginary advantages. Certainly, only such a man should be allowed by our statutes to invoke its assistance in the treatment of diseases, however insignificant.

—Corning, *Med. Record.*

SPINAL CONCUSSION.—In closing a discussion upon this subject, at the American Medical Association, Dr. Clevenger said he had been astonished at the improvement of some patients after the settlement of damage claims, but this seemed to be due to the relief from worry which the conclusion of the suit afforded; but it would be presumption to affirm that such cases were *entirely* cured until years had elapsed and unprejudiced opinion been engaged. This "quick cure by settlement" savored too much of the unscientific assertion of Herbert Page, who was the most ordinary special pleader for railways.

While both Dr. Gapen and Dr. Judd had been opposed to Dr. Clevenger in recent suits against corporations, and seemed to look at the matter from one standpoint, the latter had frequently been called as expert for either side, and sometimes for both sides at the same time.

The statement that there were no vaso-motor centers in the spinal cord, and hence the symptoms were cerebral, was rather surprising, when the sympathetic system is so intimately united to the spinal all the way down the cord length, and such ordinary matters as constipation and hemorrhoids producing brain troubles show that such "vaso-motor" difficulty as emotionalism need not have its origin necessarily in the head.

The intimation that subjective symptoms were always false, when made the basis of claims against railways, is on its face absurd. Physicians have to judge from the consistency of symptoms whether they were real or not.

Contrary to Dr. Gapen's findings, Dr. Clevenger had devoted all his spare time for three months in analyzing Erichsen's cases, and found an abundance of objective signs in all. But it depends upon what is meant by "objective." To the uneducated the galvanometer and electrical indications convey no meaning. Paralysis and insanity of the gravest kinds would present nothing "objective" to the biased witness. There are cases in which no honest opinion can be reached, and in such it is best to allow the mind to remain a "scientific blank," as Huxley advises. Only the untrained imagine they must have a positive opinion upon everything under the sun. Sometimes a little waiting will determine matters.

A case examined a year ago presented nothing but purely subjective symptoms, and to day there is atrophy of an arm. In another instance a laborer fell partly into a coal hole, with one leg in and the other out, and after a year is unable to do any work, but there was such an utter absence of anything in the way of electrical or other findings, and so many of the ordinary symptoms of Erichsen's disease were missing, that Dr. Clevenger told the lawyers that everything depended upon the credibility of the witness, and he preferred having nothing to do with the case as it stood at present.

We find many instances, in and out of the books, of fatal issues among patients accused of malingering. We occasionally find a conscientious railway surgeon who acknowledges that railway accidents do not always improve health, and that a few dollars' settlement will not resurrect the dead.

—*Jour. Amer. Med. Assoc.*

ANTISEPTICS.—The antiseptic plan of testing typhoid fever has only of late occupied the attention of medical men. This plan of treatment has grown out of the germ theory concerning the disease, and I am inclined to the opinion that it is the only rational way to treat this trouble, since we pretty well all agree that it is essentially a germ disease. Now, I do not claim, by any means, that as yet we have a specific absolute for typhoid fever, but I do say that, as sure

as there is any certainty in medicine, *there is a specific* for typhoid fever, and I believe with our modern antiseptic practice the disease is as capable of being cut short as many other diseases about which we raise no question as to their abortion. If we accept Mendenhall's and Waugh's theory, that the symptoms of typhoid fever are caused by decomposition in the bowel—and I am sure it is the most rational—how can we believe otherwise than that it is cut short by remedies preventing such putrefactive changes? True, we may not prevent it after such change has *actually* taken place, but even then many of its distressing symptoms may be cut short, or even prevented. The distressing nervous symptoms, such as delirium, subsultus, etc., are now by some of the most distinguished men regarded as the invasion of the products of germ action, and in proportion as these germs increase will their product increase and these symptoms be aggravated. Now, then, if by modern asepsis we prevent the formation of the germ, or by antisepsis we destroy the germ, and such productions, with their destructive results, cease, what goes with the theory of self-limitation? Will the remedies do this? Why not? Will they not prevent putrefaction and decomposition in other cases? Why not in this? If they will in other circumstances, most certainly they will in this. What are the remedies most likely to do this, and at the same time that are not hurtful in other respects? First of all I put mercury. Why? It has been a custom almost as long as we have had any knowledge of medicine to give mercury on the beginning of all febrile disorders. This practice has been routine and empirical in most ca es, and yet a world of good has come from it. All authorities agree that our own systems have in them a laboratory which produces a substance far richer in antiseptic powers than almost any compound dispensed at the hands of the most skilful chemists, and this substance we call bile. It is a fact that it will prevent decomposition in the alimentary tract as nothing else will. So, then, in order that we shall have the quickest and most successful disinfection of the bowel, we must stimulate the liver to thrown out an extra amount of this fluid, and there is nothing that will more successfully do this than mercury in some form, besides it in itself is highly antiseptic. The preparation I like best in these cases is the protoiodide in 1-100 grain doses every hour till its effects are produced. Many times I use calomel in small doses with good results. Who knows but that the old dose of calomel has aborted many a case of typhoid fever by this means. I believe it, although given with an entirely different purpose. Next to mercury comes zinc sulpho carbolate, sub-carbonate of bismuth, naphthaline, resorcin, carbolic acid, iodine, the mineral acids, etc.; preferable among these I like the sulpho carbolate of zinc in two or three grain doses every two or three hours. I have found it an excellent remedy, especially when there is an astringent antiseptic needed.

—Broughton, *N. C. Med. Jour.*

RAPID AND EASY METHODS OF ESTIMATING UREA AND SUGAR IN URINE.—The apparatus for the estimation of urea consists of a pipette with one graduation, and marked 1 c. c., and a graduated tube about 1 c. c. in diameter and about 30 c. long, and closed at one end.

The process depends upon the decomposition of urea by hypobromite of sodium, producing nitrogen, carbon dioxide and water. The two latter bodies remain in solution, while the nitrogen escapes. The measure of the nitrogen is depended upon to calculate the weight of urea which produced it.

I use two solutions, and mix them when used. These are a twenty per cent. solution of potass. bromide and Labarraque's solution of hypochlorite of soda, which, when mixed, produce the hypobromite of soda and chloride of potassium.

The graduated ureometer is filled to the sixth mark with the solution of potass bromide, then to about the fifteenth mark with Labarraque's solution, and finally to about the twentieth with water. With the pipette add 1 c. c. of urine, and close the ureometer with the thumb and invert a few times to mix thoroughly. When effervescence ceases the height of the liquid is noted; the open end is then plunged into a vessel of water, the thumb removed, the tube is lowered until the surface of the water within and without the tube are on the same level, and another reading taken. The difference between the two readings gives at once the number of grains of urea in each fluid ounce of the urine under examination.

The graduations of the instrument represent grains per fluid ounce when 1 c. c. of urine is taken.

For the estimation of sugar, the solution used is Fehling's, with a small quantity of potass. ferrocyanide to prevent precipitation of red oxide of copper. By this procedure we are better able to see the discharge of the blue color of the copper solution. The apparatus consists of a short burette, terminating in a comparatively wide delivery-tube, beveled at the end. The delivery-tube passes through a cork in the neck of a flat-bottom flask of four ounces capacity. Another tube, bent at right angle, passes through the same cork, for the escape of steam. The burette is graduated in c. c. and also with a second graduation, representing grains per fluid ounces, when 5 c. c. of Fehling's solution are taken.

The process is performed as follows: Fehling's solution is poured into the burette until it is filled exactly to the 5 c. c. mark, which, on the burette, is marked F. A 1 to 20 solution of potassium ferrocyanide is added until the 7 c. c. mark is reached.

The stop-cock is now opened and the liquid allowed to run into the flask. The burette is filled with water, and this is allowed to flow into the flask. The apparatus is now put upon a sand-bath, and allowed to come to a boil. The burette is now filled to the zero mark with the urine to be examined, and added carefully until the blue color of the solution in the flask is discharged. The exact point is easily seen. It is only necessary to read off the grains of sugar per fluid ounce on the left-hand graduations.

In most cases of diabetes it will be necessary to dilute the urine to about five grains per ounce after a preliminary test. This is easily done in the burette. We may simplify the preparation of the solution by adopting the following formula for the preparation of Fehling's solution, which is now usually made in two parts and mixed when needed for use:

SOLUTION NO. 1.	
Copper sulphate	34.65 c. c.
Dist. water	500.00 "
SOLUTION NO 2.	
Rochelle salt	1.73 c. c.
Caustic soda	200.00 "
Potass. ferrocyanide	50.00 "
Water	500.00 "

For use, mix equal quantities of these two solutions, measured out with the burette. I have had but a few months' experience with the keeping power of Solution No. 2; but, so far as I have tested it, there is no reason for not adopting this formula.

—Bartley, *Brooklyn Med. Jour.*

FRENCH NOTES.

By A. E. Roussel, M.D.

Sudden Death Following Simple Catheterism of the Uterus for the Production of Abortion.—M. Gibert communicates the following observation to the Medico Legal Society: A woman, four months pregnant, resolves to have an abortion produced. The woman to whom she addresses herself introduces into the canal of the cervix of the uterus a small rubber syringe. But at this moment, and before having made the least injection, the patient, who has partaken of a copious breakfast one hour before, is attacked by syncope, which becomes more severe, and is followed by death in five minutes.

It is possible that the fact of having indulged in a copious repast was an unfavorable circumstance, as the abortionist — who admitted having performed more than one hundred abortions—desired to postpone the séance until another day. It is also remarkable that a simple injection of liquid is sufficient to detach the membranes.

The autopsy revealed no lesion whatsoever; it is therefore probable that the death by syncope was due to a phenomenon of inhibition, already observed in cases of a similar nature.—*L'Union Médicale.*

Iron Pills (Huchard).—

℞.—Extract of cinchona,
Extract of gentian,
Extract of rhubarb,
Potassi tartrate of iron . . . āā 72 grains.
Extract of nux vomica . . . . . 3 "
Oil of anise . . . . . gtt. v.
Glycerine, q. s.
For one hundred pills. Take two pills before each meal.

M. Decroix mentions the deleterious influence of tobacco on the functions of generation. He supports this affirmation by numerous observations, and concludes by demanding that the academy formulate a law preventing the use of tobacco before the age of sixteen years.—*La France Médicale.*

The Constant Galvanic Current in Gynæcology.—Dr. Apostoli delivered an address at the Berlin Congress, of which the following are the general conclusions and summary:

1. The constant galvanic current is principally indicated in gynæcology, in endometritis, and in fibroma; the sovereign treatment in painful and circulatory troubles (amenorrhœa, dysmenorrhœa, and metrorrhagia), it is a powerful remedy for arresting the evolution of non-malignant neoplasms, and aids the reabsorption of extra uterine exudations. It exercises a very salutary resolutive action in many peri-uterine inflammations, and in certain catarrhal ovaro-salpingitis, but it is inefficacious, and even hurtful in large doses, particularly if the intra-uterine pole is without action against the suppurating inflammation of the annexes.

Its variable intolerance, which increases with the inflammatory condition of the annexes, should serve as a precious means of diagnosis, to determine the existence and the nature of peri-uterine liquid collections (hematic or suppurating) unsuspected or simply doubtful, and should serve to hasten in those cases delayed or refused surgical intervention.

2. The effects of the constant galvanic current are polar and inter-polar. The inter-polar action, trophic and dynamic, which increases as the square of the intensity furnished is added to the polar action; the latter is utilized first by the different action of each pole, which Apostoli has made known, then the calorific action developed by the passage of the current (to augment the intestinal circulation), and finally the antiseptic action of the positive pole, which Apostoli and Laquerriere have recently given experimental demonstration.

3. The elevated galvanic applications, employed in various ways, above 50 milliamperes, according to the tolerance of the patients, and other clinical indications form the fundamental basis of the method of Apostoli and find their justification:

(*a*) First in the utilization of the circulatory drainage, direct consequence of the calorific action due to the resistance of the passage of the current, and proportionate to the square of the intensity.

(*b*) In the antiseptic action or microbicide, which increases with the intensity produced.

(*c*) In the rapidity and efficacy of the effects produced, which are proportional to the square of the electrical energy, after an analogous formula, to that of the measurement of the energy of other natural forces: $Q = \frac{1}{2}$ m b 2.

(*d*) In the generalization, more easy of method in rebellious cases (hard fibromas, and sub-peritoneal, endometritis, etc.) and in young women.

(*e*) In the eloignement of the relapses, which, other things being equal, will be that much less to be passed, the more intense has been the application.

4. If the vaginal application of the galvanic current (which is the method created by M. Chéron for fibromas only, and applied since by A. Martin, Braeht, Meniere, Onimus, Carpenter, Mundé, etc.) produces results, they are very inferior to those of the intra-uterine application, which should remain the method of choice:

(*a*) Because it utilizes above all the maximum of the current produced, and of its energy.

(*b*) Because it utilizes the antiseptic action of the positive pole which is altogether local, and which is done away with in the inter polar circuit and at the level of the negative pole.

(*c*) Because it often adds a diurative and caustic action to the intra-uterine application, thus treating at the same time either a simple endometritis, or the endometritis which so often complicates fibroma and the peri-uterine inflammations, insuring in this way a more rapid cure, more complete and more permanent.

(*d*) Because it furnishes, to a better extent than vaginal applications, the relief of pain, and renders

more tolerable the employment of high doses, and finally it assures a greater efficacy in rendering possible an increase of the intensity applied and the sanguine irrigation which accompanies it.

5. Vaginal punctures made at a depth of a few millimeters (from 2 to 5) by means of a filiform trocar of gold, insulated in all its extent excepting at the point, forms the complement often very salutary of intra-uterine therapeutics, created by Apostoli, in better localizing the galvanic action and in rendering more efficacious, in certain cases, the application of small and moderate doses.

6. The innocuity of his intra-uterine therapeutics affirms for itsef: First, as compared with the bloody method of intra-uterine curettage, and particularly as regards the statistics furnished by the entire world as compared with his own. From July, 1882, to July, 1890, he has made 11,499 galvanic applications, distributed as follows: 8,178 intra-uterine positive galvanic caustics; 2,486 intra-uterine negative galvanic caustics; 222 vaginal galvanic punctures positive; 614 vaginal galvanic punctures negative.

He has treated 912 patients, comprising 531 fibromas. 133 simple endometritis, and 248 cases of endometritis complicated by peri-uterine inflammations divided into :

Clinic : 313 fibromas; 70 simple endometritis; 163 cases of endometritis complicated by peri-uterine inflammations.

Private : 218 fibromas; 63 simple endometritis; 85 complicated endometritis.

He has had three deaths, which may be attributed to operative failure (two galvanic punctures, one for a sub-peritoneal fibroid, the other for an ovaro salpingitis; one galvanic caustic for a cyst of the ovary mistaken for a fibroma).

He has observed thirty cases of pregnancy following after intra uterine galvanic applications.

ITALIAN TRANSLATIONS.

By William F. Hutchinson, M.D.

From Il Giornale dell' Exercito e della Marina.

Dr. Robert Messalongo states that all symptoms produced by gastric derangement, such as vertigo, tinnitus aurium, headache, general weakness, etc., do not depend upon structural change in the stomach, but are the expression of an auto-infection of the blood by toxenes developed by chemical decomposition of the ingesta in abnormal conditions. The author of this statement has experimentally demonstrated these toxenes in dyspepsia, and found that their inoculation gave rise to pathological manifestations identical with those of that disease.

Dyspepsia, therefore, is nothing but an auto-infection of the system kept up by altered innervations of the stomach. During and after digestion in normal conditions, there is always some slight production of these toxenes, but they are destroyed during their passage through different organs in their course.

He concludes that the most rational treatment for this disease will be, in acute cases, to relieve the stomach of these agents by emetics, at the same time neutralizing their strength by antiseptics. To restore innervation to its normal condition, tonics should be given.

Euphorine: A New Antipyretic.—The class of synthetic remedies for reducing febrile temperatures has been increased by the introduction of the compound named above. It occurs as a white crystalline powder with a faint aromatic smell and slight taste, recalling that of cloves. It is soluble in alcohol or in mixtures of alcohol and water, and hence its administration in mixtures, or even merely dissolved in wines, is facilitated. A number of physiological experiments were made which proved (1) that it does not produce any changes in the blood; (2) that it is non-irritant; (3) that in healthy persons it seems (in doses up to three grains) to be inert; (4) that no phenol, aniline, albumen and sugar are excreted in the urine of the animal taking it. It will be convenient to give the dosage before speaking of the therapeutics: As an antipyretic for patients under fifteen, eight grains are given in two doses with an interval of half an hour; for adults, fifteen to twenty-four grains daily. As an anti rheumatic twenty to thirty grains daily are required, and the analgesic effect is produced by doses of fifteen to thirty grains daily. Euphorine proves useful in various acute and chronic febrile disorders. On the average the effect was produced in one half to one hour, culminated in three hours (or rarely six), and lasted from five to seven hours. As the temperature went up again rigors were observed and profuse perspiration; during the apyrexia patients felt quite comfortable. Cyanosis and collapse were rare and transient. The effect of the remedy was marked in acute febrile rheumatic conditions; fever and pain disappeared, the affected parts became less sensitive to pressure, and the power of movement was increased. Over chronic rheumatism it appears to have less influence. What seems to be a very promising property of the compound is its antiseptic power; it was tried upon ulcers of long standing, and chronic cases of ophthalmia; in these, ulceration was promptly arrested and healthy granulation set up. Euphorine has been successfully given by Professor Giacosa, of Turin, and also by Dr. Sansoni, both of whom studied its therapeutic action in a number of cases.—*Hospital Gazette.*

Medical News and Miscellany.

At the Presbyterian Hospital, Chicago, Nov. 7, a child died from the effects of chloroform while undergoing an operation for the removal of a small mole from the cheek.

Dr. W. J. Hearn has been appointed Lecturer of Clinical Surgery at Jefferson Medical College. He is at present one of the visiting surgeons to the Jefferson and Philadelphia Hospitals.

Dr. J. C. McPherson, of Lyons, N. Y., while on a visit to Chicago, was knocked down by footpads and seriously injured. The thieves were frightened away before securing the doctor's valuables.

Prof. John J. Reese spoke on What Constitutes Reliable Evidence in Criminal Poisoning," before the Medical Jurisprudence Society at the hall of the College of Physicians, Thirteenth and Locust streets, Philadelphia.

Children's Aid Society.—During the month of October the Children's Aid Society, 127 South Twelfth street, found situations for forty-seven mothers at service, every mother taking one child with her. There were also eighteen children placed in private families to board, and nine were placed in private families on trial.

SOME very strange accidents are brought to light by the accident insurance business. For instance, a man at Zaliska, Ohio, a stationary engineer, was kicked very severely by a hog. It disabled him for quite a number of weeks, and he was paid $97. Another case was that of a man at Chillicothe, Ohio. As he was stooping to pick up some kindling wood a game rooster gaffed him in the wrist, cutting an artery, which disabled him for some time.

THE theatres threaten to prosecute claims for damages against the city, for interference with their business. Sore throats, alleged to be due to Mr. Wagner's newly improved gas, have almost broken up the companies at some of the principal theatres. It is rumored that the throat specialists contemplate a petition to the Director, asking him to continue the present method of manufacture. The sale of lamps during the past month has been enormous.

THE BRAIN AND SPINAL CORD.

They may talk of the brain and point with pride,
To its arching dome and its basis wide;
To its cortical cells and its ganglia deep,
And the treasures of thought its chambers keep,
To the wonders which eye and ear enthrall,
But the spinal cord surpasses them all.

For the eye will close, and the brain will tire,
And our thought in its very source expire;
While the lordly brow with lowered crest,
Seeks the downy pillow in needed rest;
But the sentinel cord its vigil keeps,
For "the spinal system never sleeps."

The brain may suffice for our waking hours,
When the mind controls its wayward powers.
'Tis by it we laugh and by it we weep;
It leaves us to die when it goes to sleep,
But the tireless cord with a ceaseless play
Is wakeful and active both night and day.

When the powers of life seem about to yield,
The brain is the first to resign the field;
But the spinal cord holds out to the last,
And it often conquers when hope is past,
Survives the weak maunderings of the brain,
And ushers us back to the world again.

Then here is a toast I would have you hail,
The spinal cord from the bulb to the tail.
You surely must honor the famous spot
Where Flourens located "the vital knot."
The cord! the cord! with its mysteries deep,
Which the pyramids guard and the ganglia keep,
The first to grow and the last to fail,
The spinal cord from the bulb to the tail.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy and Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from October 24, 1890, to November 1, 1890.

Leave of absence for one month, with permission to apply for an extension of fifteen days, to take effect upon the arrival of Acting Assistant-Surgeon, A. P. Frick at Fort Navey, is granted Surgeon Stevens G. Conway, U. S. Army. Par. 2, S. O. 112, Dept. of Arizona, Los Angeles, Cal., October 24, 1890.

By direction of the Secretary of War, the leave of absence granted Captain Charles B. Ewing, Assistant-Surgeon, in S. O. 131, September 22, 1890, Dept. of the Missouri, is extended fourteen days. S. O. 250, A. G. O., October 25, 1890.

Headquarters Department of the Platte, Omaha, Nebraska, October 27, 1890. Leave of absence for one month, on surgeon's certificate of disability, is granted Captain Guy L. Edie, Assistant-Surgeon, U. S. Army, Fort Douglas, Utah. S. O. 80.

Leave of absence for one month to take effect about the 31st instant, is granted First Lieutenant J. D. Glennan, Assistant-Surgeon. Par. 1, S. O. 146, Dept. Mo., October 23, 1890.

By direction of the Secretary of War, the following changes in the stations of officers of the Medical Department are ordered:

First Lieutenant Charles E. Woodruff, Assistant-Surgeon, is relieved from duty at Fort Gibson, California, and will report in person to the commanding officer, Fort Missoula, Montana, for duty at that post, relieving Major Calvin DeWitt, Surgeon.

Major DeWitt, upon being so relieved, will report in person to the commanding officer, Fort Hancock, Texas, for duty at that post. Par. 6, S. O. 249, A. G. O., Washington, D. C., October 24, 1890.

First Lieutenant Philip G. Wales, Assistant-Surgeon, is relieved from station and further duty at Fort Huachuca, Arizona Territory, and assigned to duty at San Carlos, Arizona Territory, where he is now temporarily serving. Par. 13, S. O. 254, A. G. O., October 30, 1890.

So much of paragraph 2, S. O. 208, A. G. O., September 5, 1890, as directs First Lieutenant Nathan S. Jarvis, Assistant-Surgeon, to report for duty at San Carlos, Arizona Territory, is revoked. On the expiration of his present sick leave of absence, Lieutenant Jarvis will report in person to the commanding officer, Fort Bayard, New Mexico, for duty at that station. Par. 13, S. O. 254, A. G. O, October 30, 1890.

Captain William J. Wakeman, Assistant-Surgeon, is relieved from duty at Fort Bidwell, California, to take effect on the final discontinuance of that post, and will then report in person to the commanding officer, Fort Huachuca, Arizona Territory, for duty at that station. Par. 12, S. O. 254, A. G. O., October 30, 1890.

Captain William H. Arthur, Assistant-Surgeon, is relieved from duty at Fort Bayard, New Mexico, and will report in person to the commanding officer, Fort Grant, Arizona Territory, for duty at that Fort, relieving First Lieutenant William B. Banister, Assistant-Surgeon. Lieutenant Banister, on being relieved by Captain Arthur, will repair to this city, and report for duty to the commanding officer, Washington Barricks, District of Columbia. Par. 12, S. O. 254, A. G. O., Washington, D. C., October 30, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending November 1, 1890.

STEPHENSON, F. B., Surgeon. Detached from Receiving ship "Wabash," and wait orders.

MARTIN, H. M., Surgeon. Ordered to the Receiving ship "Wabash."

STONE, LEWIS H., Assistant-Surgeon. Ordered to the U. S. S. "Pinta."

ARNOLD, WILLIAM F., Assistant-Surgeon. Detached from the U. S. S. "Pinta," and granted two months' leave.

OWENS, THOMAS, Surgeon. Detached from the Coast Survey steamer "Blake," and wait orders.

BLACKWOOD, N. J., Assistant-Surgeon. Ordered to the Receiving ship "Vermont."

BOGERT, E. S., Assistant-Surgeon. Detached from the U. S. Receiving ship "Vermont," and to the Coast Survey steamer "Blake."

MOORE, A. M., Surgeon. Detached from the U. S. S. "Kearsage," and to the Naval Hospital, Mare Island, Cal.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service from October 6, 1890, to October 25, 1890.

HUTTON, W. H. H., Surgeon. Detailed as chairman, Board of Examiners; ordered to Washington, D. C., for temporary duty, October 14, 1890.

WYMAN, WALTER, Surgeon. To inspect quarantine stations, October 14, 1890.

LONG, W. H., Surgeon. Detailed as chairman, Board of Examiners, October 14, 1890.

SAWTELLE, H. W., Surgeon. Granted leave of absence for five days, October 13, 1890.

GASSAWAY, J. M., Surgeon. Granted leave of absence for thirty days, October 11, 1890.

IRWIN, FAIRFAX, Surgeon. Detailed as recorder, Board of Examiners, October 14, 1890.

AMES, R. P M., Passed Assistant-Surgeon. Granted leave of absence for thirty days, October 14, 1890.

WHITE, J. H., Passed Assistant-Surgeon. Granted leave of absence for thirty days, October 24, 1890.

PETTUS, W. J., Passed Assistant-Surgeon. To proceed to Vineyard Haven, Mass., for temporary duty, October 9, 1890.

PERRY, T. B, Assistant-Surgeon. Ordered to examination for promotion, October 9, 1890.

KINYOUN, J. J., Assistant-Surgeon. Ordered to examination for promotion, October 10, 1890.

CONDICT, A. W., Assistant-Surgeon. To proceed to Baltimore, Md., for temporary duty, October 18, 1890.

RESIGNATION:

AMES, R. P. M., Passed Assistant-Surgeon. Resignation accepted by the President, to take effect November 15, 1890, October 14, 1890.

PHYSICIANS' FAVORITE PHAETON,

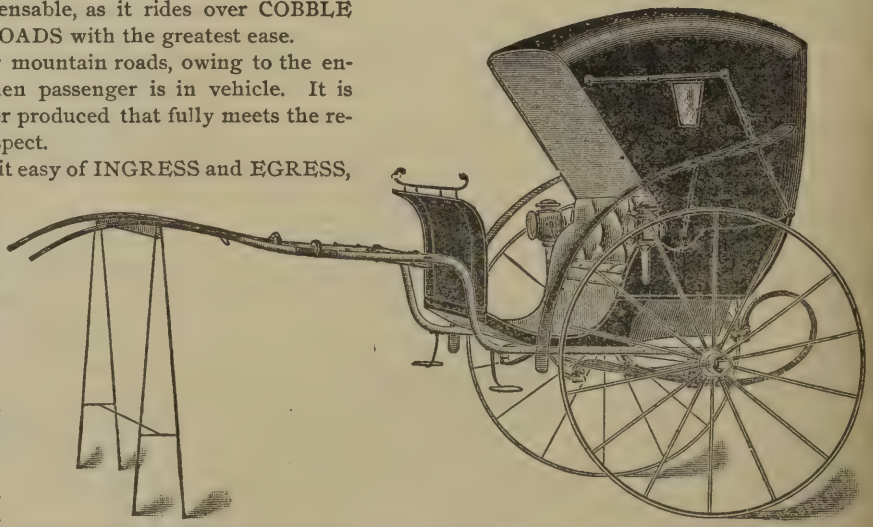
Guaranteed to be Absolutely Free from Horse Motion or Weight on Animal.

THE CHADWICK TWO WHEELER.

For Physicians' use it is indispensable, as it rides over COBBLE PAVEMENTS or FROZEN RUT ROADS with the greatest ease.

It is especially adapted to hilly or mountain roads, owing to the entire absence of weight on animal when passenger is in vehicle. It is entirely new and the only vehicle ever produced that fully meets the requirements of a physician in every respect.

The low hang of the body renders it easy of INGRESS and EGRESS, thus overcoming one of the most monotonous parts of the physicians' practice. In the upholstery of the seat and back, it affords the greatest luxury. Has regular Physician's Close Top, with large side lights, stationary storm apron on dash, large drawer under seat for instruments or medicine case, and is furnished with large serviceable French Cylinder, oil burning reflector lamps when desired.



Most Perfect, Stylish, and Easiest Riding Physicians' Cart Ever Built.

Built with pole for team, instead of shafts when desired, as in the absence of weight on animal, it is the only two wheeler to which a pole can be successfully used. Making it of greater ease and of lighter draught for animal to handle, than any two or four wheeled vehicle ever produced.

Send for Illustrated Catalogue and Price List. Correspondence Solicited.

THE TREATMENT OF FIBROID TUMORS OF THE UTERUS.[1]

BY GEORGE H. ROHÉ, M.D.,

Professor of Obstetrics and Hygiene in the College of Physicians and Surgeons, Baltimore; Gynecologist to St. Joseph's Hospital.

THE object of this paper is to advocate a rational discrimination in the treatment of fibroid tumors of the uterus.

Uterine fibroids differ greatly in size, situation, structure and character of the symptoms to which they give rise. The treatment demanded by these differences likewise varies.

In structure, fibroid tumors are homologous with the tissue of the organ in which they are found. They are composed of muscular and fibrous tissue in varying proportions, usually encapsulated by a connective-tissue capsule, in which large vessels ramify. In some cases, the growth is made up principally of muscular tissue, in others almost exclusively of white fibrous tissue. In the majority of cases, however, the growths are composed of varying proportions of these two tissues, sometimes the muscular, at another the fibrous predominating.

Most fibroid tumors, especially if of moderate size, are firm and solid, but the larger growths frequently have cysts or cavities filled with a lymphoid fluid. These fibro-cystic tumors often cause no little difficulty in diagnosis, being sometimes mistaken for ovarian cysts, at others confounded with pregnancy. It must not be forgotten that pregnancy and fibroid tumors may co-exist, although happily this combination is not very frequent.

Fibroid growths may occupy any portion of the uterus. Their site of predilection appears to be the fundus and posterior wall of the corpus uteri. Schroeder found 92 per cent. in the body of the uterus, and only 8 per cent. in the cervix.

With reference to their situation in the uterine walls, fibroids are usually classified into sub-mucous, sub-serous and interstitial.

The sub-mucous project into the uterine cavity, the sub-serous toward the cavity of the abdomen, and the interstitial occupy a more or less intermediate position between the inner and outer walls of the uterus. As a matter of fact, most large fibroid tumors begin as interstitial or intramural growths, and become sub-mucous or sub-serous in consequence of the contractions they excite in the muscular walls, which force them either inward or outward.

Fibroid tumors may undergo fatty degeneration and be absorbed; they may slough and be cast off through the genital canal; they may undergo calcareous change and become encysted, and be thus carried through life; or may slough out in the form of concretions which have received the name of uterine stones. Finally, they may undergo sarcomatous degeneration and become malignant. All of these terminations are, however, exceptional. Generally the tumor continues growing until, or after, the menopause, and gives rise to symptoms more or less troublesome, and in many cases sufficiently serious to demand active measures of relief.

The most pronounced symptoms of fibroid tumors of the uterus are pain, hemorrhage and interference with the functions of other organs by pressure. They may also produce great discomfort by their weight. Occasionally the sub-mucous variety undergo sloughing, when they may cause the death of the patient by septicæmia.

The pain produced by uterine fibroids is sometimes so severe as to be alone a sufficient reason for medical or surgical interference. It usually manifests itself at the menstrual periods as dysmenorrhœa, but may be constantly present as severe backache, bearing-

[1] Read before the Medical and Chirurgical Faculty of Maryland, November 12, 1890.

down simulating labor pains, especially in the sub-mucous variety, or neuralgia of the sciatic nerves. Sometimes there is persistent pain in the uterus itself, or more probably in its peritoneal covering, which is subjected to irritation or inflammation.

Comparatively small fibroids situated low down in the uterine walls, or in the cervix, may cause severe irritation of the bladder by pressure. There is often vesical tenesmus with frequent micturition, causing the most intense suffering.

The pressure upon the rectum may also give rise to constipation and great pain on going to stool. Hemorrhoids and œdema of the lower extremities are not infrequent complications due to interference with the venous circulation. During the menstrual periods these pressure symptoms are generally increased in severity. Intra-pelvic or intra-abdominal pressure may also cause ascites, and in some cases localized peritonitic processes.

Hemorrhage is in most cases the symptom that urgently demands remedy. It is most frequent and gravest in the sub-mucous tumors, but may be an accompaniment of any variety. It may be alarming in cases where the tumors are so small as to be detected with difficulty on bimanual palpation. The bleeding usually occurs at the menstrual periods which are prolonged and more profuse than normal. The menstrual interval may be normal in duration, but in many cases is shortened, so that the bleeding recurs in two or three weeks. The blood is frequently discharged in large clots. Indeed, the discharge of clots at the menstrual period is an absolute indication of something abnormal, and should always invite attention to the condition of the uterus. In a very large proportion of cases it will be found to be an outward sign of fibroid growths.

A definite relation exists between uterine fibroids and sterility. Whether the sterility is a cause or a consequence of the morbid growths is not positively determined. Statistical compilations show that about 75 per cent. of the women having fibroid tumors have never borne children. This may be regarded as fortunate, for in cases of labor complicated with uterine fibroids over half of the mothers and nearly two-thirds of the children die.

The treatment of fibroid tumors of the uterus is pre-eminently surgical. Even the administration of ergot and savine may be looked upon as a surgical method of treatment, for the effect striven after in the use of these remedies is the extrusion, or partial extrusion of the growths, whose removal is completed by surgical means. While the deaths directly due to the use of ergot are probably few, most writers discountenance the treatment for these reasons: The ergot treatment is tedious, painful, often ineffective, and even at times dangerous. When the tumor is forced into the uterine cavity, or through the cervix by the contractions induced by the medicine, the practitioner must be ready to interfere surgically, otherwise sloughing and sepsis are imminent.

The ideal operation for a fibromatous tumor is the removal of the tumor, leaving the uterus intact. Unfortunately, in many cases this result cannot be attained. Nevertheless, this should be striven for wherever possible. The marvelous success of Schroeder and Martin in enucleating fibroids, and thus preserving the uterus, should encourage us to an imitation of their work. The enucleation of fibroids, whether by the genital canal, or by laparotomy, is in the true line of conservative surgery.

When a sub-mucous tumor projects into the uterine cavity, or the vagina, its attachment is usually by a pedicle of greater or less thickness. When the pedicle is thin the tumor may be twisted off. The torsion seems to arrest all hemorrhage at the same time from the highly vascular mucous membrane covering the pedicle. When the latter is thick, attachment may be severed with scissors, ecraseur, or galvano-caustic wire. I prefer the latter method as less dangerous, cleaner, more rapid, and thoroughly aseptic.

When the tumor is attached by a sessile base, the mucous membrane and capsule over it may be split with a knife, after carefully dilating the cervix under aseptic precautions, and then enucleating the tumor from its base. To arrest hemorrhage a tampon of iodoform or creolin gauze may be packed against the bleeding surface. Great care is requisite, however, not to allow the tampon to remain too long, as the secretions may be backed up through the tubes, and cause salpingitis or other inflammatory disturbances in the pelvic cavity. I am sure I produced a pelvic peritonitis in one case by the improper use of a tampon to arrest hemorrhage after amputation of the cervix.[1]

Sloughing of a sub-mucous fibroid is not necessarily fatal, as careful disinfection of the genital canal, before and after the operation, will often avert sepsis.

Vaginal enucleation of sub-serous tumors of the cervix may sometimes be practised. The operation was first done by Czerny. An incision is made through the vaginal fornix, avoiding the large vessels on the sides of the cervix, and the tumor enucleated from the tissue of the cervix and the pelvic connective tissue.

Tumors of considerable size may be delivered by intra-uterine and vaginal enucleation. If the growth is too large to remove entire, it may be diminished in size by subdividing it with scissors, saws, specially devised for the purpose, or the galvano-caustic wire. The operation should always be completed at one sitting; for to allow part of the tumor to remain is an invitation to septic absorption. Judgment and experience are required, however, to decide when the growth has reached a size that does not permit its safe removal by way of the vagina.

The enucleation of fibroids through an incision in the abdominal wall—laparo-myomectomy—is indicated in certain cases where the tumor cannot be removed by the vagina. It is at once a graver operation than the latter, and accompanied by a considerable mortality. If the tumor is sub-serous, and attached by a thin pedicle, its removal after section of the abdominal walls is not difficult. The pedicle may be transfixed by a double ligature, and tied tightly, the tumor cut off above the ligature, the peritoneum stitched over the end of the stump, and the external wound closed. Unfortunately, the tissues of the pedicle often shrink after the tumor is removed, and hemorrhage may take place from the stump. To avert this accident various measures have been adopted by different operators. Some remove a wedge-shaped plug from the face of the stump, and sew the opposing rough surfaces firmly together by deep and shallow sutures, lastly bringing the peritoneum together over all. This is usually efficient, but consumes valuable time. Other operators clamp the stump in a wire snare (Koeberle's serre-nœud), or a constrictor

[1] In reference to this point, Sir Spencer Wells says: "I have occasionally put on one or two pairs of pressure-forceps to a pedicle, either before cutting away the polypus, or when bleeding occurred after cutting away, and have left the forceps hanging out of the vagina for several hours; and I prefer this method to the more common one of applying perchloride of iron, and plugging the vagina."

of parallel steel bars (Keith's clamp), and bring it outside of the abdominal wound, where the constricted portion of the stump mummifies or sloughs off. The peritoneal covering of the sides of the stump is stitched to the parietal peritoneum, and so closes the peritoneal cavity against any discharges from the end of the stump. This method gives better results than the intra peritoneal method, but leaves much to be desired in the way of surgical neatness and rapidity of healing. It is also at times attended by other inconveniences and dangers, especially if the pedicle and uterus are much put upon the stretch.

When the growth of the tumor is sessile and directly under the peritoneum, or covered by a very thin layer of uterine tissue, it may be enucleated by making a bold incision over the tumor, and shelling it out of its base.

To guard against excessive bleeding an elastic ligature—a piece of rubber tubing—may be tied around the cervix, including within the ligatures the arteries supplying the uterus and appendages. Even large growths may be removed in this way. If the cavity left in the uterine tissue is too large to get good coaptation between its walls, it may be packed with iodoform gauze, as practised by Fritsch, and the edges stitched to the abdominal incision, in order to secure free drainage and make the cavity accessible to external treatment.

Deep intra-mural, or even sub-mucous tumors may be treated by this method, but the results are less and less favorable the more the uterine cavity is opened.

Sometimes the uterine walls are so occupied by the new growths that their total removal can only be accomplished by the excision of the entire uterus, or at least that portion above the cervix. This operation is one of the gravest in surgery, and gives, in the hands of nearly all operators, a high mortality. The total extirpation of the uterus, including the cervix, by way of abdominal section, has not been very often done, but with present methods should give more favorable results than supra-vaginal hysterectomy.

In the latter operation the stump very often gives trouble either from hemorrhage or sepsis.

Complete removal of the uterus at the vaginal junction, approaches the conditions of vaginal hysterectomy, and should give very little higher mortality than the latter. However, at best, the complete or partial extirpation of the uterus is an operation of great gravity, and should only be resorted to when all other means promising success have been tried.[1]

Tait has called especial attention to the soft œdematous myo-fibroma, which often gives the impression, on examination, of containing cysts. This tumor frequently fluctuates in size, being now larger, now smaller, without any apparent cause. These, as well as fibro-cystic growths of the uterus, are particularly suitable for complete extirpation by abdominal section. No other operation or method of treatment seems to control their growth or arrest the hemorrhage which is a frequent accompaniment.

In 1872, Lawson Tait, of Birmingham, and Alfred Hegar, of Freiburg, almost simultaneously devised the operation of removal of the uterine appendages —ovaries and Fallopian tubes—with the view of artificially inducing the menopause and thus arresting the growth of fibroid tumors by cutting off the principal source of blood-supply to the growth. This operation has now probably been done over one thousand times with very satisfactory results. Tait's own results, as shown in a statement recently furnished by him,[1] are extremely favorable. In 426 cases, 16 died, a mortality of 3.75 per cent. Tait also declares that 95 per cent. of the cases of fibroid operated by removal of the uterine appendages are cured, that is to say, the bleeding is arrested and a large proportion of the tumors diminished in size, some disappearing altogether. These effects have been established by many observers, especially when the cases have been properly selected. As above pointed out, in the soft œdematous growths the arrest of the bleeding does not seem to follow so regularly as in the hard, nodular fibroids.

The cause of the arrest of the hemorrhages, after renewal of the appendages, is probably due, as suggested by Mr. Knowsley Thornton,[2] to cutting off the blood supply by ligature of the large vessels in the broad ligament, and not merely to removal of the ovaries and Fallopian tubes. As a matter of fact the mere extirpation of the ovaries alone often fails in producing the expected result.

The high mortality of the abdominal hystero-myomectomy, and the opposition on many sides to the removal of the ovaries, which it was claimed by many, unsexed the woman,[3] led Dr. George Apostoli, of Paris, about 1882, to experiment with the galvanic current in the treatment of uterine fibroids. It is true, Cutter, Kimball, and perhaps others, had used galvanism successfully for this purpose before, but Apostoli developed a method by which the application of electricity is reduced to scientific exactness. The improvements in the instruments for generating, measuring and applying electricity now permit the physician to administer this remedy, with as much exactness in dosing as any other therapeutic agent at his command. It would take too much time here to describe the apparatus or the methods in use. For a full description I refer to pages 327-350 of "Practical Electricity in Medicine and Surgery," by Liebig and Rohé, and to Dr. G. Betton Massey's excellent little book on "Electricity in Diseases of Women," both published by F. A. Davis, Philadelphia.

In 1887, Dr. Apostoli reported 278 cases treated by this method with a successful result (arrest of hemorrhage, diminution in size, disappearance of pain and pressure symptoms) in 95 per cent. The average number of applications was fifteen in each case. In August, 1889, Dr. Thomas Keith and his son, Dr. Skene Keith, published a detailed record,[4] without commentary, of 106 cases treated according to the method of Apostoli. The average number of applications in the cases treated to a termination was twenty-eight. Three of the cases died during or shortly after the discontinuance of the treatment, but in neither case was the fatal result attributable to the applications. Admitting, however, for the sake of argument, that the electricity was the cause of death, a mortality as low as 3 per cent. cannot yet be claimed by any operator in hysterectomy, and even in the comparatively safe operation of removal of the appendages, very few operators can show as favorable results, as Keith has obtained with electricity.

[1] Several American surgeons have done complete extirpation of the uterus successfully, and A. Martin reports eleven recoveries out of sixteen operations, a pretty high mortality.

Fritsch's mortality in all cases of hystero-myomectomy, including enucleations is 25 per cent. Bantock's 22 per cent.

[1] Mac Naughton Jones: Diseases of Women; Fourth Edition, p 340.

[2] American Gynecological Transaction, 1882.

[3] This objection is not tenable, as the "unsexing" consists merely in anticipating the menopause, which is one of the natural characteristics of the human female.

[4] The Treatment of Uterine Tumors by Electricity, Edinburg, 1890.

I have carefully gone over the record of the cases reported by Keith, and have been surprised at the almost uniform improvement noted. Diminution in size of the tumor, arrest of hemorrhage, relief of pain, and general improvement in the nutrition and spirit of the patient are recorded in nearly every case.

August Martin, the greatest living gynecological surgeon of Germany, has very recently[1] referred to 10 cases treated by him in the following words: "The results in these 10 cases show that hemorrhage, the most troublesome and dangerous symptom of myomata, may usually, indeed, be controlled; in fact, in those large multiple tumors, which apparently were situated intra-murally, and included the fundus, hemorrhage ceased nearly entirely. Several small tumors were not influenced in the same manner, and the hemorrhages continued unchanged in spite of very frequent sittings, so that here the result must be regarded as a very doubtful one. One patient, who had a myoma of the size of an ostrich egg, had such violent pains after seven sittings, that she insisted upon being operated. The operation was performed, and the patient recovered. A second symptom, often so frequently complained of, is the phenomena of pressure. These disappeared in all of 9 cases, so that in this respect the result is very satisfactory. An essential decrease in size has, up to now, not been obtained in any case."

This is not very enthusiastic, but Dr. Martin admits that the symptoms for the relief of which hysterectomy is at all justifiable, were relieved in his cases. He states that he shall continue "making experiments with the procedure."

Numerous other competent observers in France, Germany, England, and in this country, have had successful experience with this method, and although there is still a good deal of sneering at the method as being useless, and withal dangerous, and those who use and advocate it are denounced as quacks and "low down, no-account sort o' pussons" generally, electricity in the treatment of fibroid tumors of the uterus has come to stay, and demands investigation. Ridicule and denunciation are no answers to plain records of facts submitted by Apostoli, Zweifel, Martin, Keith, and many others, less eminent, perhaps, but still of some account in the world.

Some of those who use the electrolytic method, apply it in office or dispensary practice, allowing the patients to walk or ride considerable distances after the application. This I regard as imprudent, and likely to cause trouble. All the cases in which serious symptoms, or a fatal result followed after the use of electricity were such as had imprudently exposed themselves. I regard it as important that several hours at least of perfect rest should follow each application. To allow this course to be pursued it is requisite that the patient should be treated at her own home, or in a properly fitted institution.

It goes without saying that careful asepsis of the genital canal should be maintained during the electrical treatment, as well as in the gravest and most delicate surgical operations.

Laparo-hysterectomy puts the woman in jeopardy of her life, and keeps her a helpless invalid for at least one month. The electrolytic treatment keeps the patient under moderate restraint for a period of two or three months, does not endanger her life, and leaves her generally in such a condition of comfort and health that she is satisfied to live her allotted days, even though she is obliged to carry her tumor with her to the grave.

I would not advocate the exclusive use of electrical method in the treatment of uterine fibroids. As stated in the beginning of this paper a rational discrimination is demanded of those who treat this condition. Many cases are readily relieved by vaginal or intra-uterine division of the pedicle by scissors, ecraseur, or galvano cautery wire; others are best treated by vaginal, intra-uterine, or abdominal enucleation. Large œdematous tumors or fibro cysts should be treated by laparo-hysterectomy; bleeding fibroids of not too great size, are proper cases for removal of the appendages, and most large chronic, immovable tumors, choking up the pelvis, causing pain, pressure-symptoms and hemorrhage yield to the proper, patient employment of the galvanic current after the method of Apostoli.

[1] Introduction to American Translation of Martin on Diseases of Women. Boston, 1890. p. xxix.

SHOULD HYPNOTISM HAVE A RECOGNIZED PLACE IN ORDINARY THERAPEUTICS?

By NORMAN KERR, M.D., F.L.S.,

Fellow of the Medical Society of London; President, Society for the Study of Inebriety; Vice-President International Congress of Medical Jurisprudence; Corr. Mem Medico-Legal Society of New York, and American Society for the Study and Cure of Inebriety. Author of "Inebriety: Its Etiology, Pathology, Treatment, and Jurisprudence," etc.

AS I read, recently, in the columns of a medical journal, of a grave assemblage of medical practitioners giving utterance to feelings of astonishment at the painlessness of that generally agonizing process, the extraction of teeth, and other painful operations, at the reception of false beliefs and the display of eccentric contortions, while the persons operated on were unconscious of their vagaries, I could not help conjecturing that these, my learned professional brethren, were but rubbing their eyes while awakening from more than a quarter of a century of sleep as profound as that of the eleven thousand virgins of Cologne. Where had these Esculapian eyes been all these years?

Nearly thirty years have come and gone since, a fledgling in medicine, I witnessed even more mysterious performances than these hypnotic phenomena which have lately been over-awing medical and lay Rip van-Winkles. I might have alluded to the wonderful exhibitions of a like character in the days of Mesmer, fully one hundred years ago, and have gone a long way further back in the East for similar exhibitions; but at present it may be judicious to speak what I do know and testify what I have seen.

In my judgment, the hypnotic or mesmeric wave is a neurotic epidemic which we, who profess the art of healing, have to run the gauntlet of, like measles, sooner or later in our professional career. I had both badly in my medical infancy, and, having escaped troublesome sequelæ, have no longing for a second attack of either.

Let me clear the ground by at once accepting as genuine most of the phenomena which have recently been claimed for hypnotism (though some at times occur independently of induced hypnosis) by Liébault, Heidenhain, Van Eeden, Tuckey, and others. It is true that there have been trickery and collusion in some alleged mesmeric or hypnotic displays, but almost every kind of demonstration is liable to simulation and fraud. The deception which has been practised in mesmeric and hypnotic performances may be left out of account. I have no doubt of the genuineness of the hypnotic phenomena favored by some of our professional brothers.

Undoubtedly persons have been sent artificially to sleep, and, while in that hypnotic state, have borne without consciousness, manipulations which would have given them acute pain had they been in full possession of their senses. In that state such persons have been made to accept false beliefs as real, and to assume all manner of attitudes at the will of the operator. Undoubtedly, as at Madras by Eisdale forty years ago, major operations have been performed on natives without the infliction of a pang or the recollection, on awakening, of an ache. Undoubtedly pain has been relieved and some ailments have apparently been cured by hypnotic suggestion, as of late at Nancy, Paris, and Amsterdam, and formerly in our own country by Gregory and Braid. Undoubtedly, while in a state of artificially induced somnambulism suggestions can be impressed on the susceptible subject, which may last for a longer or shorter period, which within certain limits may be carried out at a given time suggested by the hypnotist.

Freely acknowledging all these facts (which, with additional phenomena, I have verified), it may be asked: "How do you account for them?" I candidly confess that I cannot, though plausible explanations have been attempted, such as the most recent, "disturbed inhibition." Closely as I have watched the phenomena of hypnosis I have been able hitherto to discern only a disordered cerebral state, an abnormal psychical condition characterized by exaltation of receptivity and energy. The neurotic susceptibility to hypnosis, like the religious epidemics of the middle ages, breaks out now and again, and for a limited period may by mental contagion possess a community.

Having thus conceded the claim put forth, on behalf of hypnotic suggestion, as in some instances effecting certain immediate apparently beneficial results in susceptible subjects, it remains to consider whether such a means of alleviating the suffering of some is desirable and justifiable in ordinary therapeutics.

In determining this question various considerations must be taken into account.

1. Only a limited number of patients can be hypnotised. This is specially true of the Anglo-Saxon race.

2. In many persons, after hypnosis, nerve equilibrium is apt to be disturbed, the nervous balance upset, and nerve energy dissipated. Such have an intense feeling of languor and exhaustion, indicative of profound neurasthenia. This neurasthenic collapse frequently repeated may lead to deterioration of brain and nerve function—a physical degradation as well as an intellectual decadence and a moral perversion. There are neurotics whose appetite (under hypnosis) for *outré* actions is insatiable, who, when hypnotised cannot get too many and too eccentric tasks to perform. In these cases this morbid desire increases at each *séance*. This is a kind of non-alcoholic inebriety, a form of teetotal intoxication, which presents grave aspects, not to be found in alcoholic or any other narcotic intoxication.

3. Hypnosis is not a healthy but an unhealthy condition, a disorder of nervous function, an abnormal state. When we meet with similar phenomena in hysterical subjects on whom no hypnotic influence or suggestion has been attempted by any one, we have no hesitation in recognizing and treating these trance and somnambulistic manifestations as symptoms of morbid nervous perversion. Why should we show such neurotic phenomena greater deference when they are artificially produced? Why should unintentional auto-hypnosis be deprecated as a symptom of disease calling for medical treatment, as when undesigned auto-hypnosis has been induced by rapt, absorbed, devotional gaze on some sacred image, and hypnosis, by intention and at the suggestion of another person, be cherished as a healthful help to recovery from disease?

4. Whatever the immediate effect of hypnotic suggestion, a true though temporary neurosis has been set up. Charcot, from his observations at the Salpêtrière, has noted three stages in hypnosis, the lethargic, the cataleptic, and the somnambulistic. Especially in the lethargic, and to a large extent in the cataleptic, the unconsciousness is apparently complete. In these two stages the patient does not move. For the moment his will is inoperative. In these stages he is rarely amenable to suggestion. In the third stage, that of somnambulism, he can read and hear, he can receive and carry out the suggestion of the operator who hypnotises him. When he wakes, he can remember nothing that happened during his hypnotic sleep, though he may automatically carry out the suggestions which had been made to him, which may recur to him at the next somnambulistic *séance*, unless an opposing suggestion has been impressed upon the brain. All these phenomena, as well as the somewhat loosely defined five hypnotic "degrees" of the Nancy School, constitute a chain of abnormal neurotic symptoms. A departure from health has been artificially induced. It does seem to me that while in the flesh we are liable enough (especially in these days when to the multiform and omnipresent bacteria and microbes a tremendous potentiality of disease generation is ascribed) to bodily and mental maladies without, like the artificial hatching of chickens by the incubator, rearing by art an innumerable progency of some of the most subtle ills to which flesh is heir—disorders of the brain and nervous system.

Thus, even if it can be demonstrated that a disease may be cured by hypnotism, this is accomplished only by a disadvantageous exchange of maladies, the substitution of a graver diseased state, a transformation, a metamorphosis which, however sensational and brilliant as a *coup de théâtre*, is not a truly curative process, and should have no support, unless in extraordinary circumstances, from such members of the medical profession as practice their calling with a single eye to the genuine healing of the sick. There are circumstances in which the production of a less serious disease is justifiable and useful, for example, in a resort to vaccination as a protection against the greatly more fatal disease of small-pox, and in the temporary cerebral disturbance of a narcotic (which has not the power of a hypnotist to modify its action) for purposes of permanent or greater evanescent benefit. To establish a case for hypnotism under these exceptional conditions it fails to be shown that the cerebral disorder produced thereby is less grave, in character and potentiality, than the original malady and other remedial measures.

5. Is disease really cured by hypnotism? Though I have seen pain relieved and distress alleviated in a few cases by mesmerism and hypnotism, I much doubt if disease is often cured thereby. Some physicians, in the height of their new-born amazed delight at agony assuaged as by a charm, have assumed that a cure has been effected. This is often a premature conclusion. It is generally easy to obtain a respite from pain. But that blissful interregnum is no proof of the cure of the disorder of organ or func-

tion from which the pain took its origin, and of which unhealthful disturbance it was a portentous and timely warning. A patient, consuming away with an agonizing ailment, breaking through the dietetic restraint under which his life was being prolonged, enjoys a complete, though evanescent respite from his sufferings during a paroxysm of intoxication. But the disease from which he is dying is not cured, rather aggravated.

Though the sensation of pain may be abolished for a time and a painless interval be secured, it does not follow that good remedial work has been done. Very often pain is but an emphatic message, like an urgent telegram, to call our attention to something radically wrong in our internal economy. If in such cases we deaden the pain we are only silencing the unwelcome though merciful and necessary messenger, by which pain-killing lulling us into false security, the disorder within may acquire increased lethal power. It is, however, in certain circumstances, legitimate to endeavor to obtain relief from pain, when its severity or persistence, apart from the pathological origin of the suffering, is unbearable, or perilous to reason or life.

The few cases I have seen derive apparent, if temporary benefit, would probably have done as well under ordinary treatment had they not either resisted that, or been passive, instead of giving themselves up as they did to the hypnotist. They had a wish for cure and strong faith in the process, the efficacy of which was heightened by the congenial and impressive surroundings. Under such favoring conditions there would be a fair crop of successes for "faith healing," the "mind cure," the "movement," the "blue electricity," or any other "cure." The greatest success which has been claimed for hypnotic suggestion has been in the alleged cure of nervous affections. My observations is that this is the very class of ailments which, though apparently improved for a time, is in the end confirmed and intensified. Of one group of diseases of this kind I can speak with some precision. It has been asserted, especially by some non-medical hypnotists, though also by a very few medical enthusiasts in hypnotism, that they have cured a larger proportion, than by any other means, of their cases of what they are pleased to call "dipsomania." An erroneous designation by the way; for, unless when suffering from "hot coppers" after a debauch, many inebriates are never thirsty. Such do not drink because they like the intoxicant. On the contrary they often hate it with a perfect hatred. "Tipsymania," as Punch christened it, is a more accurate term. Inebriety is truly an intoxication-mania, or, as I have ventured to call it, a torpor or Narcomania. Though hypnotism has been tried in inebriety by several medical experts, it has not been found useful as a remedy by a single American or English expert specialist of repute in the treatment of any form of that protean malady.[1] Of course there is a certain percentage of cures under hypnotic treatment, as indeed there is with no treatment at all, by sheer self-determination. Inebriates usually put themselves under the hypnotist and give themselves up to him. I have seen such cases cured without hypnosis and without residence in a Special Home. But, frequently, inebriates entering such a Home do so under pressure. Indeed, I have known inebriates made thoroughly drunk, and even drugged, and taken to a Home without their consent or knowledge. In these circumstances a thoughtful and experienced physician would see little hope of cure.

The last occasion on which I induced hypnosis was years ago on an inebriate, in an emergency to save my life; when my windpipe was steadily being compressed by a strong man in delirium tremens, who had me in an unguarded moment at his mercy in the corner of a steamship's cabin, powerless to cry out for help. Yet the suggestion, though effectual at the time, had little post-hypnotic permanence.

In the treatment of alcoholomania, morphinomania, etheromania, and other allied diseases, I must, however, acknowledge that, in addition to hygienic, pharmaceutical, and other therapeutic measures, I largely make use of suggestion. By this I mean healthy suggestion, not suggestion as employed by Bernheim to induce morbid eccentric manifestations.

Suggestion is employed by all physicians, consciously or unconsciously, if they have at heart the welfare of their patients, or even if they have any decided opinion. The stronger the faith of the patient in the physician the better is the hope of benefit. When the patient hangs upon the lips of the doctor, the latter's every direction or expression of opinion is practically a suggestion of the purest and most satisfactory character, impressed permanently upon an expectant and receptive brain. Such a suggestive process is as unobjectionable as it is remedial and scientific. There is neither pitfall for the suggester nor peril to the suggestee, for both are in the full possession of consciousness. Suggestion in hypnosis is, so to speak, a mechanical impression on a soulless unthinking mass, which suggestion may or may not have a post-hypnotic life. Non-hypnotic healthy suggestion is an interchange of intellectual thought, a reasoning appeal to an intelligent and sentient being. To sound suggestion must be ascribed the success and the reputation of our best alienists and physicians.

6. The dangers involved in the practice of hypnotism are very great. To succeed in obtaining an apparent cure, in many cases the *séances* have to be repeated for a more lengthened period than often suffices for the malady to run its course, when treated by orthodox medicine. At each sitting the subject comes more and more under the control of the operator, till a spiritless subservience to the operator's will may lay hold of the hypnotee, who in some cases degenerates into a mere automaton without any backbone, a jelly-fish mass without mind or will of his own. This is a state of mental serfdom which is infinitely worse than days of pain and nights of agony. There are such wrecked lives among us, the unhappy results of former well-intentioned medical and non-medical hypnotism. What chiefly opened my eyes to the perilous tendency of hypnotism, was the onset in some apparently highly benefited cases, in the practice of as honest a man as ever lived, of mental instability developing, in at least one case, into insanity.

7. One peculiarly grave occasional consequence of repeated hypnotic acts is that between the operator and the subject, a subtle affinity or *rapport* may develop, which may involve both subject and operator. This obscure affinity of affectivity may, by a process of involuntary non-hypnotic auto-suggestion, insensibly yet gradually grow upon the performer till

[1] To dissipate a misapprehension which I had not foreseen, it may be judicious to explain, that by specialist-experts, I mean medical men who have devoted themselves mainly to the scientific study and treatment of inebriety as a disease, and who have had large numbers of inebriates under their care.

he is in danger, though sorely against his will, and despite a strenuous struggle, of being unable to resist dangerous morbid impulses. In the person of both parties such an unhappy issue may co-exist with fervid emotional religion.

8. Hypnotic suggestion is liable to other grave abuses. The hypnotist may commit an offence upon the hypnotee during the lethargic and cataleptic states; and may by suggestion (even sometimes when not in the presence of the subject) force the hypnotee (in the somnambulistic state) to commit a criminal act, and at the same time refuse to disclose whether the suggestion had been made, and, if so, who was the author. Five cases of the first category are recorded by Gilles de la Tourette in his "L'Hypnotisme au Point de Vue Médico-Légal" (Paris, 2d ed., 1889), and cases of the second category have also been the subject of judicial procedure (Castellan, 1865, and other cases).

So liable to abuse has the practice of hypnotism proved in France that the French army and navy surgeons have been forbidden to practice it on their patients; and in Belgium it is proposed to enforce certain restrictions in civil practice.

9. Apart altogether from these grave abuses to which hypnotism is liable, the fact remains that some of the hypnotized come quite under the control of the hypnotist, mere puppets in his hands. This is a weighty objection to which no answer has been attempted. I can conceive no circumstances which can justify the placing of the control of a man's or woman's thoughts and actions in the keeping of a fallible fellow-mortal; no circumstances which can warrant the dependence of any one's sobriety or insobriety on the pleasure of another person.

The plea has been offered that no one can be hypnotised unless he choose. This is, generally speaking, true in the main, but (1) no small number of human beings are ever ready to be the prey of anything new or bizarre, and (2) repeated, persistent, cunningly devised attempts by a skilful and experienced hypnotiser may secure that degree of fixed attention, expectancy, and mind concentration, and break down the resisting power to that level, where further resistance is unavailing.

It has been contended that the possible abuse of this remedy is no objection to its deliberate use, as with chloroform. To this it is sufficient to reply that chloroform has only a restricted effect on body and brain, and is a material substance, the action of which is limited and known; whereas hypnotism places the trained subject at the mercy of another individual open to temptation and auto-suggestion to abuse his capacity to inflict untold mischief on the body and morals of the submissive subject.

It may be urged that the hypnotee may resist suggestion in the hypnotic state. This does occur in some cases, but is the exception. The restoration and re-assertion of long dormant inhibition is an arduous and difficult task, few having the courage and perseverance to succeed.

In view of all these possible abuses and dangers, it passes my comprehension how it could ever have been contended that family medical practitioners should practice hypnotism on patients of both sexes and all ages, as a part of their regular daily work. Surely the perverted actions of hysteric patients, and the existing chances of groundless and serious charges to which we are already exposed, are more than enough, without the addition of hysteria-cum-hypnosis complications. In such a prospect the question would appropriately arise: "Is medical life worth living?"

I cannot find language strong enough to express my abhorrence of the disgusting and degrading exhibitions to be seen in many public places of amusement, as well as in select circles of fashion, sometimes for mere amusement, sometimes in philanthropic guise, sometimes for pure gain honestly enough professed, at which men, women, and young people are made to perform ridiculous antics, and to unconsciously play the fool, to the detriment of their mental health and the depraving of the public taste. Such demoralizing performances have been suppressed in Holland and Switzerland, which countries have set an excellent example for Britain to follow. I have read, with a glow of shame on my cheek, that reputable physicians have patronized such entertainments, and by their testimony, in addition to their presence, have thrown the ægis of professional sanction over the saddening and regrettable proceedings. The performers, though culpable, have usually the excuse of striving for a livelihood, and in my opinion are not nearly so blameworthy as are their medical patrons.

If, notwithstanding the nervous and mental disorganization which it frequently induces, hypnotism continue to be considered lawful, the practice of it ought not to be allowed (except in an emergency) unless for strictly scientific purposes, as in the study of the psychology of the phenomena,[1] or therapeutically in very exceptional cases, by responsible medical men, in the presence of at least one other duly qualified colleague, with a third adult (such as a trained attendant or nurse) present, a record being kept of each *séance*, its object and its results. There should also be recorded as accurate an after-history of the cases as can be obtained.

With these precautions a minimum of risk would be run; but, with our present knowledge, as regards therapeusis, I candidly confess that I would infinitely rather see the medical profession set its face against the whole hypnotic process as a hazardous and unreliable remedy, never free from the risk of perilous sequelæ, involving serious medico-legal responsibility, liable to the gravest abuses, operative with only a limited number of persons, the general tendency of which is apt to be inimical to the best interests of patient and physician, to induce hysteric and allied morbid affections, to produce cerebral conditions conducive to mental unsoundness, and to transmit to posterity permanent pathological nervous susceptibilities, with an ill-balanced and unstable brain, more especially in these days of nerve riot, exhaustion, and unrest, when o'erwearied nature yearns with an unutterable yearning for even the briefest space of oblivion and repose.

"Hypnotism and hysteria are very near of kin." "Hypnotism is a genuine neurosis, not a physiological state."—Charcot, 1890.

NOTE.—Puységur published rules for treatment by hypnotic suggestion, with cases, one hundred and six years ago.

GEORGE KEIL has in preparation a medical and dental register-directory and intelligencer for the States of Pennsylvania, New Jersey and Delaware, to be ready early in 1891. He desires to have from every physician data as to his graduation, residence, office hours, etc. The publisher's address is 1715 Willington street, Philadelphia.

[1] I well know how intensely interesting such a study is, but it is so absorbing and fascinating that in the interest of both observer and observed, it is imperative to exercise constant vigilance and self-restraint for the preservation of sound mental health.

Society Notes.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON ORTHOPÆDIC SURGERY.

Stated Meeting October 17, 1890.

V. P. GIBNEY, M.D., Chairman.

NON-UNION OF FRACTURED RADIUS.

DR. C. A. POWERS exhibited a patient in whom this condition had existed for many years, and also showed an extension apparatus which had given relief. The first fracture occurred twenty-nine years ago at the junction of the middle and lower thirds. A refracture took place eighteen years later, and united with deformity and disability. The radial nerve had become involved in the callus, and this gave rise to such intense pain that she underwent an operation for its relief, five years later, in which the bone was again fractured. All attempts to cause this fracture to unite failed. When she came under the care of the speaker, in May of the present year, it was found that the carpus had slipped upward with the lower fragment of the radius, and had caused the ulna to project very forcibly against the soft parts, giving rise to much pain in the region supplied by the ulnar nerve. As further operative measures were not deemed advisable, a simple extension apparatus was applied, and had answered admirably.

DR. A. M. PHELPS said that he thought it had been wisely decided not to subject the patient to further operation, as fractures of the radius, and of the lower third of the tibia, were peculiarly prone to non-union. Out of about three hundred osteotomies, he had had only one case of non-union, and that was after an operation for the correction of an anterior tibial curve. Operations by himself and others had failed to bring about union. Thomas, of Liverpool, claimed that such fractures could be made to unite by pounding the parts with a mallet; but in his experience, this method had not proved successful, and he thought that where there was muscle between the ends of the bone, and the peculiar, ivory-like condition of the ends of the bone—which was not uncommonly present — none of the methods heretofore proposed were likely to prove successful. He had very recently proposed and performed a new operation, which he thought might prove successful. It consisted in cutting down upon the ununited fracture, freshening the ends of the bone, and grafting in between them a part of the forearm of a dog—both patient and dog being secured in plaster of Paris. When the graft had united firmly, the dog's leg would be amputated, and the skin flaps of the dog united to those of the patient.

HIP-JOINT DISEASE AFTER TYPHOID FEVER.

DR. J. MCG. WOODBURY presented a girl of eleven years, who, six months after a severe attack of typhoid fever, was found to have some limitation of motion and pain at the right hip, with distension of the capsule. Flexion caused lordosis, and some pain. She was treated by counter irritation over the joint, and a plaster of Paris spica bandage, and was allowed to walk around upon a high patten, with crutches. Now, after a period of eight months, there was no pain.

A CASE OF OSTEO-MALACIA.

Dr. Woodbury also presented a case of this nature. The patient had lived in Switzerland until twenty-six years of age, and had suffered considerably from exposure during the late war. On October 26, 1886, when forty-three years of age, he sustained a fracture of the surgical neck of the left humerus, and between that date and May 26, 1890, he received five other fractures—viz., two of the left humerus, two of the right humerus, and one of the left clavicle. Most of these fractures were caused by very slight falls. During the last three months—but more particularly since the first of last August—a tumor has been rapidly growing between the sites of the two fractures of the shaft of the right humerus. Two small tumors may be observed upon the clavicle—one at the point of the fracture, and the other to the inside of it. A specimen, removed from the large tumor with a harpoon, was sent to Dr. J. S. Ely for microscopical examination, and he reported that it contained "polyhedral cells, and occasional large spindle and giant cells." He adds that this "speaks very strongly for sarcoma." A loud murmur, similar to that heard in aortic aneurism, is audible over the large tumor. Dr. Woodbury said that as in cases of tumor of the middle of the spinal cord, osteo-malacia, due to trophic disturbances, is one of the early symptoms, concurrent with disturbances of sensation, he had referred the case to Dr. M. A. Starr, with the hope of learning more about the etiology of this interesting condition. Dr. Starr examined the patient on two or three occasions—the last time only a few days ago—and had reported that there was no central lesion of the cord. The patient had had no pain with the fractures, or upon resetting these bones, and this, together with the fact that there had been no fractures of the lower extremity, seemed to favor the view that the condition was due to a syringe myelia, or tumors of the cord.

DR. POWERS said that Dr. Woodbury's case of multiple fracture with tumors was very similar to a case of multiple sarcomata which he had recently presented to the Surgical Section.

DR. V. P. GIBNEY thought the pulsation in the tumor might be due to the condition of the tumor itself. In other words, it might be a pulsating sarcoma.

ANKLE-JOINT DISEASE.

DR. A. B. JUDSON presented a case of this disease which he said was interesting because the child had suffered from this condition almost all her life. The disease began at the age of one year, and she is now about seven years old. Notwithstanding that she had been under mechanical treatment only two years, she had recovered with but little disability and deformity. There was considerable lateral motion at the ankle-joint; extension was almost normal; flexion was arrested at about 90°. Scars on both sides of the ankle showed where abscesses had opened spontaneously. There was a difference of one inch between the two calves, and the shortening amounted to only a small fraction of an inch. This result had been obtained by the use of a simple brace, and without resorting to any operation.

DR. JOHN RIDLON presented an astragalus which had been removed by Dr. B. Farquhar Curtis from a child, which had been brought to the speaker when only six weeks old. He had faithfully tried stretching, and the various retentive appliances, during a period of one and a half years. Dr. G. S. Huntington had then operated by Dr. A. M. Phelps' open method, but without improving the condition. The specimen which he presented was interesting on account of two bony prominences which it showed, and which apparently had been the obstacle to flexion of the foot.

THE TREATMENT OF ANKLE-JOINT AND TARSAL DISEASE.

The paper of the evening, with the above title, was read by Dr. T. Halsted Myers, who also presented a patient illustrative of this subject.

Dr. Myers said that tubercular inflammation might attack first, the synovial membrane; later, the cartilage; and lastly, the bone; or, the primary local focus might be in the bone.

While it was still confined to the synovial membrane, a number of surgeons recommended erasion. If it had attacked the bone, many more urged operative methods, irrespective of the general health of the patient. The author considered only the latter condition.

Simple incision was of no advantage, for we had no element of tension, as in acute processess, and we only opened new channels of infection, leaving the original disease unchanged.

The usual method of treatment—curetting the abscess walls and the sinuses—could not be expected to remove all disease, and would greatly increase the risk of absorption. The success which had been secured in some of these cases seemed to be due to the power of the antiseptic agent to render inert the bacilli which remained.

The rational method was to remove all the disease at once; but apparently healthy bones contained tuberculous foci, and hence, it was a most difficult problem to know when to stop; and, in fact, this could not be determined at the time of operation. If all the disease were successfully removed, the duration of treatment was less than under conservative methods. The ultimate results were, however, less satisfactory. He had seen a considerable number of misshapen and atrophied feet after operative treatment, which were weak and painful, and required support to render them able to bear the weight of the body. He had not observed such results from conservative treatment. It was confessedly difficult to ascertain the ultimate results; and, although Dr. Shaffer had kindly placed the records of the New York Orthopædic Dispensary at his service, he had not been able, in the short time at his disposal, to do more, in most of the cases, than quote the histories.

The number of cases treated before July, 1888, was 55, and of these he knew personally that at least 21 were cured. Five were cases of synovitis, and 16 of osteitis. The average duration of treatment in the latter was twenty-one and a half months, the longest case being under treatment fifty-five months. The results in all were extremely good; yet, under careful private treatment, still better results should be expected.

From our knowledge of the various ways in which the bacilli of tuberculosis may be spread in the body, it would seem that a primary tubercular process in a joint must be extremely rare. Drs. Prudden, Northrup, Biggs, and Thacher, to whom he had written for information on this subject, all considered that these affections were generally secondary, but agreed that primary joint lesions did occur. The practical importance of this was that the danger of general infection from a joint lesion which was not interfered with surgically, was an entirely unknown, and probably extremely small, quantity.

Of the whole number treated (fifty-five), but three had died—one of diphtheria, one while tarsal disease was active, and the other, six months after a note of "nearly cured" had been recorded. In neither of the latter was the cause of death stated. However, in Dr. Scudder's report of eighteen cases of excision, six deaths occurred; three were due to the operation, or its direct effects; another might have been; and the other two were from tuberculosis, but occurred one, and two years after the operations.

The treatment of synovitis consisted in absolute protection of the joint from traumatism. In children, he considered a perineal crutch absolutely necessary while walking. Ordinary crutches were invariably laid aside at times, and the joint left unprotected. In addition to this crutch, the foot should be protected by a splint to avoid local injuries, and to maintain a good position. There being no involuntary muscular spasm, while the disease was confined to the synovial membrane, traction was not necessary.

In cases of osteitis, the same protection of the joint was imperative, and if there were pain and spasm, indicating the necessity for traction, this could be applied at the ankle, by means of a Dow's brace, or the apparatus of Dr. Sayre, or Dr. Foster.

The application of adhesive plaster to a painful ankle required more care than a dispensary case was willing to give, especially when abscess was present. For this reason, he had found it most serviceable to employ a leg brace, or plaster splint, worn constantly, and a perineal crutch for walking, which could be laid aside at night; or the Dow's brace as modified by Dr. Schaffer, might be used.

Abscesses should be left entirely alone, and the sinuses simply kept aseptic. After the joint was considered cured, it was well to wear an ankle brace for some months to prevent twists. The malpositions found in the acute stages were almost entirely due to muscular spasms, and did not require tenotomy, or other operative treatment.

In the later stages, there might be bony changes, and these, if not painful or progressive, did not require treatment. However, if these conditions did exist, and yet there was no evidence of active disease, an attempt should be made to restore and preserve the normal relations of the parts.

The value of hygienic surroundings during the treatment of these cases could not be overestimated. His observations had been made on children only, and for contrast, an extended series of cases in the adult would be very valuable. Without exception, every one of his cases of ankle joint, or tarsal osteitis in children, had done well under conservative treatment, and he had yet to see the case which he would condemn to erasion or excision.

Dr. N. M. Schaffer said that his own experience led him to think that one point in Dr. Myer's paper should be particularly emphasized, *i. e.*, the necessity of absolute protection of the articulation. He had accomplished this in practice, whenever possible, by the use of a modification of Dow's brace, and had found that adhesive plaster was rarely required, as a well fitting shoe made efficient counter-traction. He thought that the further removed the tuberculous joint was from the centre of the body, the more benign was the disease, and the less the danger of general infection; and he was inclined to speak more strongly of the conservative treatment of ankle joint disease, than of any other articulation in the body.

Dr. Ridlon thought these cases did well with the Dow's instrument; but with this, as with some others, we could not secure immobilization, but only protect the joint from the jar of walking. He had seen such excellent results in cases of suppurative ankle joint disease, without any treatment whatever, that he often doubted how much of a good result could be attributed to the treatment received.

Dr. H. W. Berg said that he had had such good results in the treatment of phthisis by the administration of the bichloride of mercury, in doses of one-twenty-fourth of a grain, three times a day, that he was inclined to believe the old theory that tuberculosis was really a change in the syphilitic virus, due to passing through several generations. He considered that splints like Dr. Judson's were imperfect, for, by taking their bearing from the outside of the foot, intra-articular pressure was increased. To diminish this pressure, the foot must be adducted and rotated inwards.

Dr. Phelps was of the opinion that the vast majority of these cases were cured by immobilization and relief of intra-articular pressure, but in suppurative cases, he believed that the soundest and most scientific surgery demanded operative measures. If we could protect the hip joint as well as the ankle joint, we ought to get equally good results in hip diseases. He believed that these cases were inoculations of pathogenic germs on a diseased surface, and that they were purely local.

Dr. R. H. Sayre exhibited a splint which his father had devised for an adult with ankle joint disease. He agreed with Dr. Ridlon that it was difficult to apply traction at this joint, but he thought this splint solved the problem. His views regarding the prognosis and treatment of this disease were in accordance with those just expressed by Dr. Phelps.

Dr. Samuel Lloyd said that fifteen cases of adult ankle joint disease had been treated in the New York Post Graduate School by the so-called conservative method, but the relapses had been very frequent, and hs thought this method was less likely to yield good results in adults than in children. In answer to questions from the Chairman, he said that several of the cases were due to injury, and a number of them were suppurative, while four were recorded as synovitis. Two of the cases had been discharged as cured before 1883, and were known to be well in 1889.

Dr. Judson protested against the statement that cases of disease in the ankle should do equally well without treatment, although neglected cases of ankle joint disease would have nothing like so bad a deformity as those at the hip.

Dr. H. L. Taylor also spoke about the different mechanical conditions present at the various joints. The weight of the limb exerted great leverage upon the joint, especially in a spasmodic condition of the muscles. It is more marked at the hip than at the knee, and very much more noticeable than at the ankle. He referred to a case of ankle joint disease occurring in a distinctly phthisical subject, where the sinuses were treated by injections of a saturated solution of iodoform in ether. The beneficial effect upon the healing process was almost magical.

Dr. Gibney said that about ten years ago the surgical section of the Therapeutic Society of this city spent about two years collecting data relative to the comparative results obtained by the operative and non-operative treatment of this condition; and the conclusion was that the conservative method yielded the greater number of useful ankles, even in cases where the foot was seamed with cicatrices. There were two or three operative cases having a high degree of equinus, and a stiffened and shortened joint, and one or two flail joints were also shown. In his experience, cases of adult ankle joint disease relapsed again and again on the slightest provocation; later on, abscesses would appear; still later, pulmonary signs would develop, and then amputation would follow. As regards the mercurial treatment of tuberculous disease of the joint, he need only call attention to the fact that many years ago the routine treatment for these cases at the Hospital for Ruptured and Crippled was one-twenty-fourth of a grain of the bichloride of mercury in tincture of bark, three times a day; and the results attained by this treatment were certainly far from striking.

The Polyclinic.

UNIVERSITY OF PENNSYLVANIA.

Prof. Guiteras has been granted leave of absence for sixty days, and started for Berlin on November 20, for the purpose of investigating Koch's new method of inoculation for tuberculosis.

Dr. Formad will lecture on pathology during the absence of Prof. Guiteras.

DR. TAYLOR SUGGESTS FOR METRORRHAGIA:

℞.—Ergotinæ . . . . . gr. xl.
Ext. nucis vomicæ . . . . . gr. x–xx.
Ferri redacti . . . . . gr. xl.
M.—Et ft. pil. No. xx.
S. One pill three times a day.

DR. PEPPER GIVES FOR HYDROTHORAX:

℞.—Mass. hydrarg.,
Pulv. scillæ,
Pulv. digitalis. . . . . āā gr. xx.
Ext. nucis vomicæ. . . . . gr. x.
M.—Et ft. pil. No. xx.
S. One pill three times a day.
Or:
℞.—Hydrarg. chlor. corros. . . . . gr. j.
Potassii iodidi . . . . . ʒij.
Spt. ætheris nitrosi. . . . . fʒss.
Aquæ cinnamomi. . . . q. s. ad. fʒiv.
M.—S. One teaspoonful thrice daily.

FOR ACUTE TONSILLITIS:

Sodii salicylatis, gr. v-x every three hours, and for local application:

℞.—Potassii chloratis, q. s. ad sat. sol.
Tr. ferri chlor.,
Glycerini,
Aquæ . . . . . āā fʒss.
M.—S. Use locally.

FOR SPASMODIC STRICTURE OF ŒSOPHAGUS:

℞.—Ferri valerianatis,
Zinci valerianatis,
Quininæ valerianatis . . . . . āā gr. xx.
M.—Ft. pil No. xx.
S. One t. d.

DR. PEPPER'S TREATMENT FOR ACUTE GASTRITIS:

1. Absolute rest for stomach.
2. Nutritive enemata.
3. To quiet stomach.

℞.—Hydrarg. chlor. mitis. . . . . gr. ij.
Bismuthi submit. . . . . ʒj.
M.—Ft. chart. No. xx.
S. One powder every four hours.
Or:
℞.—Acid. carbolic . . . . . gtt. iv.
Sodii bicarb . . . . . ʒjss.
Elixir. . . . . fʒss.
Aquæ, ... q. s. ad. fʒiv.
M.—S. ʒj every three hours.

4. Opium, hyoscyamus or asafœtida by suppository for nervous systems.
5. Counter irritation over epigastrium.

Give nothing by mouth except for its local action on the stomach.

Especially avoid all purges. If one is necessary use calomel.

FOR ATONIC DYSPEPSIA:

℞.—Zinci valerianatis. . . . . ʒss.
Ext. belladonnæ. . . . . gr. iij.
Ext. nucis vomicæ. . . . . gr. v.
M.—Ft. pil. No. xxx.
S. One pill after each meal.

THE NEW CONSUMPTION-CURE.

IT is with feelings of sadness that we note the uprising of another craze for a consumption-cure, in the public press. The time has not gone by very far since the Bergeon nonsense stirred the very depths of men's interiors generally; and the medical profession should not soon forget the result. So, now, the public has taken hold of Koch's reports, and a vivid imagination, unrestrained by any knowledge of the matter, has magnified it into a therapeutic millennium for consumptives. We will have these unfortunates, ever ready to grasp at straws, happy in the delusive confidences of a speedy cure, while sinking into the grave. Hopes will be excited in cases that are hopeless; people will rise from the bed of death, and undergo tortures to travel in search of an impossible cure. For it should not be forgotten that what we call pulmonary consumption is by no means a simple invasion of bacteria, but a most complex mixture of pathological elements. Many cases are not bacillar at all, but due to the causes of chronic inflammation in general. No "germicide" can be expected to cure an affection which is not produced or kept up by any sort of "germs." In many cases what we call consumption is simply death; molecular death. The vitality of an individual is capable of being measured quantitatively, as surely as the amount of his chest-expansion, or the force of his heart-beat. Exhaustion of the vital principle, the Jiva of Buddhist theosophy, means the extinction of vital life, and as man is not built like the deacon's shay, the feeblest of the vital organs dies first. For many reasons, civilization appears to have rendered man's lungs his most vulnerable point, and here his exhaustion of vitality appears to most frequently manifest itself. This process may be likened to the decay of the oak; or to senile degeneration in those whose vitality is great, and their organs fairly well-balanced in the power of resisting noxæ. For the first class of consumptives, we cannot look for a specific remedy until we know that chronic inflammation has a specific cause. For the second class, we must wait until Brown-Sèquard has demonstrated the vitalizing powers of testicular fluids.

Even in truly tubercular or bacillar phthisis the process is not so simple. As the case goes on there are changes in the digestive apparatus; in the tissues of the whole body; material destructions of large masses of pulmonary tissue; while pyogenic bacteria and possibly other micro-organisms join the tubercle bacillus in its work, in the dead and dying structures of the lung. Even if every tubercle bacillus is slain, and fresh invasions prevented, it is far more likely that patients who are far advanced in the disease will die from the effects of the original destroyer; and that the disease processes put in operation will still remain and prove fatal, even when the exciting cause has been removed. For these reasons we urge that hopes be not held out to consumptives in the later stages; and that, although the task is a painful one, the truth be plainly demonstrated to them.

But even with all these limitations, if Koch's injections succeed in destroying the life of tubercle bacilli in the human body, it is the most precious discovery that has ever been made by man. And while we believe that Samuel G. Dixon, of Philadelphia, originated the idea, and successfully applied it to animals, the elaboration of the method and its successful application to man by Koch are assuredly deserving of the greatest credit. Whether more of credit is due the latter we cannot decide until full details of his method have been laid before us. He has thus far simply presented the profession a brownish liquid, which, he claims, when injected hypodermically, in the prescribed doses, gives rise to certain remarkable phenomena. In healthy persons little effect is produced, in these doses. In tubercular subjects, severe general reaction occurs, with fever up to $105\frac{4}{5}^{0}$ F., pain in the limbs, coughing, great fatigue, and often vomiting. Sometimes slight jaundice or a morbilliform eruption appears. The attack begins in four hours, and continues about twelve hours; after which the patients feel about as usual, or somewhat better. In external tubercular affections, local reaction is marked; swelling and redness appearing; the diseased tissue becomes brownish and necrotic, changing to crusts, which fall off, leaving cicatrices. In lupus these changes are confined to the skin affected, that surrounding the nodules being unchanged. It is presumed that the same thing occurs in the lungs, when tubercle is present there. Koch claims that the certainty of such reaction, occurring in tubercular cases alone, renders this remedy of the utmost diagnostic value. He states that his remedy is not germicidal to the tubercle bacilli, but that it affects only the tissues enclosing the bacilli, causing them to die. Nor has it any effect on dead tissues, in which living bacilli may continue to exist, be thrown off, or re-infest the living tissues. It is therefore necessary, whenever the necrotic tissue is not quickly removed, to guard against fresh infections by continuous applications of the remedy, in rapidly increasing doses. The results of treatment in pulmonary phthisis were: An increase in cough and in expectoration, soon followed by a decrease. The sputa became mucus, and then the bacilli decreased, and disappeared, being occasionally observed later, until expectoration ceased. The

sweats also ceased, and the general health and weight improved. Patients in the first stage were cured; those with small cavities were almost cured, and when there were many large cavities no improvement could be proved. Relapses can probably be cured more quickly than first attacks. In advanced stages the same benefit cannot be expected, for the reasons stated in the first part of this editorial. Possibly a combination of surgical measures with the use of this remedy may prove of value. The question of combining this remedy with the previous treatment of tuberculosis has yet to be answered.

The nature of the remedy can, we believe, be gathered from Koch's statements as to its preservation and administration. An agent which decomposes after being mixed with distilled water, but can be preserved by sterilization or by the addition of carbolic acid, is most probably an organic substance, but not a vitalized one. It cannot be an antagonistic bacterium. These conditions can be filled by the culture-fluid of the tubercle bacillus, deprived of bacilli and sterilized, which was employed by Dixon. Meanwhile, Koch is quite right in keeping the secret to himself. The wild experimentation by ignorant persons that followed Brown-Sèquard's announcement is doubtless fresh in Koch's mind.

THE CHRISTIAN SCIENCE INSTITUTE, OF PHILADELPHIA.

THE same unquenchable yearning for knowledge that caused the representative of THE TIMES AND REGISTER to gain knowledge at the feet of Drs. McCoy and Wildman, led him also to turn his attention to No. 1524 Arch street, Philadelphia, which is labeled as "Christian Science Institute," and "Metaphysical Healing." The legend in the window, announcing that "all were welcome," put aside the natural timidity characteristic to representatives of THE TIMES AND REGISTER.

We deem it valuable for our readers to be acquainted with the various methods of fraud and quackery, so that forewarned they may be forearmed. Far be it from us, however, in giving to our readers the results of this investigation, to merely do so with the view of casting ridicule, or even doubt, upon Christian science—so-called. We will merely endeavor to repeat the interview as it occurred, and if any of our readers become hereby converted to faith-cure, *Amen;* only we would be pleased to have their names, so that we can take them off of our mail list. One must draw the line somewhere.

Our representative was ushered into a cheerful parlor, where a gentleman was indulging in a very materialistic conversation with a guest, who presently departed. We then stated to the gentleman—who, evidently, was in charge of the institute—that it was our desire to learn something of Christian science and metaphysical healing, and the work of the institute. We must, indeed, be very obtuse, for after two hours of hard talking we have, if anything, less knowledge as to what it is all about than before; and it is our firm conviction that they do not know themselves.

The subject is painfully deep, and we must be excused if we are not clear, as clearness is impossible.

1. The Christian Scientist argues that there is nothing material, and that there is no reality except spirituality; that while this present life is an actuality, it is not a reality. We hope we make ourselves clear.

2. That as there is nothing material, while our present bodies are mortal, they are not material, but are merely outcomes of our thoughts or imaginations; in a word, our bodies are nothing more or less than a bundle of thoughts.

3. Spirituality is all good; and to be perfectly well and healthy we need only believe in the truth that already exists, namely, that there is nothing material, but all is spiritual. Disease is material; and, since materiality is not real, disease is only an outcome of our thoughts; therefore, if one's thoughts are guided to the truth, or, in other words, if we are in harmony with the truth, we must deny the existence of disease; and when we are able to do this, we will be well.

"If a man with cancer comes to me," said the metaphysist, "I know that he has wrong thoughts, and that he is in enharmony with the truth; and if I can improve his spiritual condition, and make him realize the truth, namely, that there is no evil in spirituality, and that nothing is real except spirituality, then the man will get well.

"What we call 'material' is simply an embodiment of our thoughts; thus, every thought becomes materialized. Disease germs (if such exist), devil-fish, and other horrid creatures, are merely materialized evil thoughts. As soon as a certain evil thought is effaced, the devil-fish dies."

At this juncture our representative, merely for experiment's sake, mentally materialized a number of remarkable and unique animals. It was also explained that in a similar manner disease was merely the product of evil thoughts, and that, therefore, if the patient's thoughts were guided to the truth, the disease could not exist.

"If a person is in perfect harmony to the truth, no harm can come to him."

"How about a brick falling on his head?" was asked.

"Even this could not occur!"

"But," we asked, "we all have to die, do we not?"

"My dear sir," was the rejoinder, "the day is not far distant when a person will be as much ashamed to die as he is ashamed to go to jail now; and it will not be very long before we can raise the dead."

In speaking of the power of truth, the following instance was cited: An eminent Christian healer has looked at living germs through a microscope, and by merely concentrating his thoughts on the non-existence of evil, has watched those germs die at once. This man should hire himself out as a germicide.

Coming to the method of the treatment of diseases, the operator—who must be a Christian Scientist—should first enthuse spirituality into the patient, then take him into a room called "the silence," and there, mentally, for the space of ten minutes, endeavor to impress the conviction of truth upon him. The patient says to himself, "I am well; this disease does not exist; God is good, and only good can exist; I am perfectly healthy." The operator goes through a similar mental effort, only, instead of impressing the fact upon himself, "thinks" it into the patient.

In the case of disease—say membranous croup—in an infant, the operator can do all the thinking, and the only thing which can interfere with a speedy cure is doubt on the part of the parents.

These are, briefly outlined, the principles of Christian science, in which Christianity, in its true simplicity and truth, is unknown and blasphemed. To them we are all equally as divine as our Saviour.

No prayers can be offered to God. One can only meditate upon the existing truth, and impress it upon our minds. But it is not our province to deal with this view of faith-cure. Suffice it to say that it is an agglomeration of illogical and unfounded misstatements; laughs at both science and religion; and the sooner the practice of their methods be discountenanced by health authorities as gross malpractice, the better for the suffering public, both mentally and physically. They ridicule sanitation, medicine, and hygiene, and teach its defiance. Surely, the profession should be awake to these idiotic methods, and aid their suppression.

Annotations.

DR. R. J. LEVIS.

OUR readers will join in our profound regret in hearing of the death of this distinguished surgeon. Some years ago Dr. Levis retired from active professional work, so far as his attached friends would allow. He has since divided his time between European trips, yachting in the waters of Florida, and the beautiful home at Cedarcroft that was formerly occupied by Bayard Taylor. We understand that Dr. Levis died of pneumonia, after a very brief illness.

Letters to the Editor.

WHILE glancing over the columns of THE TIMES AND REGISTER recently, my attention was attracted to a report relating to the annual visit of the Inspector for the Board of State Commissioners of Lunacy, of Pennsylvania.

As a matter of information, it occurred to me to inquire if those authorized had ever visited two cases to be found in the same family, about two miles south of the village of Tylerville, so-called South Rutland, Jefferson county, in the St. Lawrence State Hospital District, New York State. J. A. W.

A SPECIFIC FOR RHUS AND IVY POISONING.

A. H., aged sixty years, a laborer, came to my office with an inflammation of the skin of the hands and forearms extending to the middle of the arm. Beginning with lotions of lead-water I tried the most effective remedies for rhus poisoning, which careful inquiry into the patient's habits proved this to be, and was much chagrined to find that nothing gave relief to the itching and burning, or held in check the inflammation.

As a *dernier ressort* a strong decoction of chestnut leaves (*Castanea Fagus*) was used, bathing the inflamed parts every three or four hours. In twenty-four hours all the distressing symptoms had subsided, and the patient was discharged cured.

Since using the above, which was in August 1888, I have prescribed the castanea treatment for all cases of rhus and ivy poisoning, and in all stages of the inflammation, with the single result in every case of perfect relief from all symptoms in from twenty-four to seventy-two hours.

I do not find this treatment in books on diseases of skin which I have read, and therefore offer it to the profession as a mite from S. B. STRALEY.

HUNTSVILLE, N. J.

REMOVAL OF PAROTID GLAND.

I WISH to report a case of removal of an enormous hypertrophy of the parotid gland, weighing after removal, one and a quarter pounds. The external carotid artery was ligated early in the operation.

I do not consider the case cancerous at all. The patient is a large woman, aged sixty-five years. The tumor has been growing for thirty-five years. An attempt at removal was made by a physician ten years ago, but given up. Her hearing was absent from pressure on this side. The pain in her face was severe and continuous, mainly from pressure on the nerves. The parotid artery was enlarged to the size of a lead pencil. I ligated this; also the temporal artery. The nerves were included in the mass, and hence were cut off. The patient made a speedy recovery. The operation was made one month ago. I do not think it will return, as I succeeded in getting every vestige of the gland from in front of the mastoid bone, and do not, as I said before, believe it to be cancerous; neither do I think it scrofulous. Prof. Henry H. Smith took rather a gloomy view of these growths of the parotid in his work on operated surgery, saying that they return and are generally cancerous. I will report if the tumor returns. This case was reported, and the tumor exhibited at the meeting of the Union Medical Association of Northeastern Ohio, in Canton, November 11, 1890.

The Medical Digest.

SULPHONAL IN DIABETES.—Dr. Casarelli, of Pisa, mentions the favorable action of sulphonal in diabetes. This drug diminishes the quantity of sugar in the urine, also reducing the polyuria and the thirst. These results were obtained by doses of from 5 to 30 grains per diem, but not to so marked a degree as with doses of 45 grains continued for several days. The 30 grain doses could be administered for some time without any ill effects; but although the 40-grain doses at first caused no disturbance, it was found that, when they were continued for any lengthened period, they caused giddiness and excessive sleepiness, which disappeared when the drug was discontinued. Sulphonal was used with good results in conjunction with both a mixed diet and a strictly meat diet; in the latter case a large quantity of sugar appeared in the urine as soon as the sulphonal was stopped. In the only case in which antipyrin had been previously used it was found to exert less influence than sulphonal.—*Lancet.*

MANGANESE.—The so-called indifferent iron preparations have been in use for some years, but they seem likely now to be replaced by similar preparations of *manganese*. The presence of compounds of both these metals in the blood is well-known, and their function as constituents of that fluid is believed to be that of carrying oxygen to the red blood-corpuscles. Manganese is further regarded as being in this respect more active.

In the first instance, however, inorganic compounds of manganeses were employed (in chlorosis, etc.), and probably owing to the insolubility of these or their non-adaptability to assimilation negative results were obtained. More recently combinations of manganese with the so-called albuminate, peptonate, and other organic groups have been studied by Dieterich. Pepto-mangan "Gude" containing about 0.6 per cent. of iron with 0.1 per cent. of manganese is much prescribed. It is a preparation which mixes perfectly with milk and wines (free from tannin) and has, according to various medical authors, a decidedly good effect in chlorotic and anæmic conditions, and in all other diseases were iron and manganese are indicated in a non-irritating and readily assimilable form.

—*Provincial Med. Jour.*

TREATMENT OF ERYSIPELAS.—Dr. Ulrich, a Danish military surgeon, having had eighty-nine cases of erysipelas of the face in young soldiers, has published in a comparative table the results of the three different methods of treatment which he adopted, viz., the application of ice compresses, painting with pine tar, and painting with a solution of ichthyol in its own weight of ether and double its weight of flexile collodion. Thirty-three cases were treated by the first method; in twenty of these the erysipelas spread considerably, in four slightly, and in nine not at all. Twenty-seven cases were treated with tar; in fourteen of these there was much spreading, in one a little, and in twelve none. Twenty-nine cases were treated with ichthyol; in these the spreading was considerable in eight cases, slight in six, and in fifteen there was none. The mean duration of the disease under the ichthyol treatment was 6.88 days, while under the ice and tar methods it was 8.33 and 9.3 days respectively. The relapses, too, were decidedly less numerous under ichthyol than under either of the other plans. Dr. Ulrich suggests that still better results might be looked for if the ichthyol were painted not merely over the affected parts, but over a considerable portion of the surrounding skin.

—*Lancet.*

CEREBRO-SPINAL MENINGITIS AFTER A BLOW ON THE HEAD.—In the *Fortschritte der Medizin*, October, 1890, Saltzman and Homén report a case occurring in a young man, aged twenty-four. The patient became unconscious after a blow on the head. When he came round he vomited vigorously; a little later he complained of giddiness and pain in the right side of the head, He was somewhat drowsy. There was no trace of an external wound.

Second Day.—Very pale; mind clear; no sensation troubles; tenderness behind right ear. Temperature, evening, 99°; pulse 60.

Third Day.—Languor and pallor increasing. Temperature, morning, 98.2°; evening, 103°. Pulse 40 and 70. During the night a strong convulsion, after which he lost consciousness.

Fourth Day.—Unconscious, though restless at times; right pupil contracted; occasionally spasm in various groups of muscles; very marked retraction of head. Temperature, morning, 100.8°; evening, 103.2°. He died in the night.

Post-mortem.—No trace of any external wound; no surface hemorrhage; along veins of pia mater unmistakable pus; spinal membranes injected; the pia mater infiltrated with pus, especially in the lumbar region; spleen enlarged.

Herr Homén calls attention to the fact that according to the investigations of Netter (*Arch. Générales*) and others the blow may possibly have determined the attack of cerebro-spinal meningitis.

EXACT DOSAGE IN THE CATAPHORETIC USE OF DRUGS.—In a paper of mine there are figured two cataphoretic electrodes devised for the anodal diffusion of drugs through the skin. The great drawback, until this present moment, has been the difficulty of accurately regulating the amount of drug introduced. For this purpose rather complicated electrodes have hitherto been required, and even these have been unsatisfactory. I have recently found, however, that all difficulties are easily obviated by the use of a new and exceedingly simple method. Messrs. Waite and Bartlett have made for me a cataphoretic electrode of metal. Instead of covering it, as before, with sponge, the ordinary metal surface is overlaid with a thin disc of platinum, and around the edge of this is placed a narrow rim of soft rubber. The drug to be used is put drop by drop upon a disc of ordinary tissue paper cut to fit the disc of platinum. Filtering paper or linen cloth may be used instead of tissue paper. A disc two or three centimeters in diameter will hold from one to four drops of the solution. When the medicated disc is placed upon the metal surface of the electrode, and the latter then applied to the skin, it is evident that there is a thin capillary layer of the drug in solution exposed to the cataphoretic power of the anode, between the electrode and the skin, and that the quantity of the drug used may be accurately estimated. The current is allowed to flow if desired until the medicated disc becomes perfectly dry. In this way we may drive in one or more drops of chloroform, methyl chloride, ether, ten to twenty per cent. solutions of cocaine, a one per cent. solution of helleborin, solutions of iodide of potassium, corrosive sublimate, aconitine—in fact, any drug we wish to employ in this manner; and at the same time we know exactly how much we are using.

To further simplify the method, I have had medicated cataphoretic discs prepared by a pharmacist for use at any time, for the paper discs may be charged with any amount of a watery solution, and, the water being allowed to evaporate, they may be kept on hand indefinitely. It is only necessary to add two or three drops of water to the disc in administering the drug by electricity.—Peterson, *N. Y. Med. Jour.*

HODGKIN'S DISEASE.—At the Medico-Chirurgical Society of Montreal, Dr. R. L. Macdonnell exhibited a male patient, aged twenty-five, a freight checker, the subject of Hodgkin's disease. Up to four years ago the patient had enjoyed good health, but about that time he suffered from a severe and prolonged attack of what was called "bronchitis." There were severe attacks of dyspnœa, which came on exertion as well as when he was at rest, and cough was very severe and brassy. He made a good recovery and continued well until two years ago, when he began to notice the presence of lumps in his neck. These have gradually increased in size. Two months ago the breathing became seriously embarrassed, and suffocative attacks of the most severe kind occurred, especially when in

a recumbent position. In the beginning of August he presented himself at the Montreal General Hospital, suffering from attacks of dyspnœa and from a bad brassy cough. On August 11 a chain of glands was removed from the front of the trachea. These were found to extend very deeply into the chest, and were continuous with other glands in the mediastinum. He made a good recovery from the surgical operation and since then has not suffered from attacks of dyspnœa, though his breath is short on exertion, and he still suffers from cough. When a boy he remembers that frequently there were large painful lumps in the armpits. Epistaxis has been frequent during the last six months. No history of any venereal disease. The glands in the left side of the neck are enlarged, prominent; distinct from each other; loosely attached; of firm structure. There are two or three enlarged glands in each axilla, but none in groin. The spleen is enlarged, but cannot be felt below ribs. The liver is of normal size. Examination of the urine yields negative result. The skin generally is clammy, but always on the left side of the forehead and face there is very free perspiration. The left pupil is much larger than the right. Examination of the heart and lungs negative. Temperature, in afternoon, has generally been 1° or 1½° above normal. Pulse is always between 100 and 110. No member of his family has suffered from enlarged glands. Examination of blood reveals a large excess of white cells. But one count has been made. For the last month Fowler's solution has been taken regularly with apparent good result. About a fortnight ago the patient experienced a sudden seizure which he described as follows: He was lying upon a sofa when he felt as if some fluid were running up in his throat; he coughed, and immediately becoming insensible fell over on the floor, injuring his head in the fall. He was said to have remained unconscious for a few minutes.—*Montreal Medical Journal.*

Panicum as a Food Article.—In *Vratch*, Nos. 37 and 38, Lipskey publishes an important paper on the *Panicum sanguineum vel Digitaria sanguinalis* as a substitute for other corn plants, especially millet and buckwheat. The plant belongs to the *Gramineæ*. In a wild state it grows in abundance all over Europe, Asia, and America. It is cultivated, as a cereal, in Bohemia, Russia, and of late, in certain regions of Germany. According to Khvoika, "this corn plant is exceedingly far from being particular in regard to either climate or soil; in fact, it grows beautifully on an utterly poor or exhausted ground, as well as on stony or rocky tracts of land, and even on quicksands." With this, the cereal is endowed with a striking fruitfulness; each seed brings forth about eighty stalks, with as many ears, or to put it otherwise, a couple of pounds of seed give a crop amounting to 4,000 pounds of grain. The latter are rather small (about half the size of a millet-seed) and are covered with a hard, grayish hull; decorticated grains being of a white color, with a yellowish tint. The chemical composition may be seen from the following table, which presents (in percentage figures) the results of numerous analyses made by Levin under Konovaloff's guidance:

	Whole Grains.	Decorticated Grains.	Panicum Flour.
Water	10.48	—	11.23
Nitrogen	2.08	1.07	0.11
Starch	40.78	73.88	85.39
Ashes	4.60	—	0.34
Cellulose, etc.	30.57	—	1.25
Fats	—	—	0.94

For the sake of comparison we adduce a table showing the composition of various grits in vogue:

	Millet.	Rice.	Pearl-Barley and Semoule.	Buckwheat.
Water	12.01	13.11	12.88	14.57
Proteids	12.25	7.85	7.25	10.96
Fats	3.31	0.85	1.15	—
Carbo-hydrates	68.91	77.15	77.55	66.71
Ashes	3.52	0.01	1.23	—

In order to determine the dietetic value of panicum, Lipsky has carried out some experiments on himself and another doctor. Each experiment lasted two days, during which the subjects' dietary consisted only of a thick-boiled panicum gruel, tea with sugar, and drinking water. It was found that one of the subjects had assimilated 62.4, and the other 60.9 per cent. of nitrogen ingested. According to Kürtcheninoff's experiments with millet gruel, the assimilation of its nitrogenous bodies varies between 49.427 and 51.254 per cent. Südakoff has found that in the case of thick-boiled buckwheat gruel the assimilation amounts to 40.4 per cent. In the case of potatoes the assimilability of nitrogenous ingredients oscillates between 49.6 and 65.1 per cent. In consideration of all the facts, Lipsky arrives at the general conclusion that "the panicum can be safely placed amongst useful vegetable food-articles."

—*Provincial Med. Jour.*

Erythromelalgia.—In the latter part of last July I was called to Mrs. G——, and obtained the following history: She was sixty-two years of age, had borne four children, and by occupation a nurse. Her parentage had been healthy, father dying at ninety-six from an accident. Her own health had always been good up to last April. At this time she was nursing a case of puerperal septicæmia, and a number of times daily had to wring out cloths dipped in hot carbolic acid solution. After doing this for several days Mrs. G—— noticed her feet to be very painful, and on examination blue and swollen on the anterior portion. These symptoms became so severe as to oblige the patient to give up her profession and take to her bed. The pain was excruciating, especially at night and on pressure, the attacks coming on paroxysmally.

When I was consulted I found her much emaciated, with atheromatous arteries, obstinate constipation, feet presenting, over the anterior and lateral aspects, especially on the plantar surfaces, irregular bluish purple spots, very sensitive, and sweating freely. Urinalysis gave negative results.

The treatment consisted of a ferruginous tonic, the usual hygienic measures, and cold affusions locally; while the general condition improved the local did not. The local application of belladonna, hot water, etc., failed. Electricity only aggravated it. I then decided to put her on arsenic—the liq. acidi arseniosi—directing it to be pushed until physiological symptoms became manifest.

After several days of this treatment the patient began to improve, and six days after walked around the block with ordinary shoes being the first time in months that she had been able to tolerate any covering on her feet. Improvement went on so rapidly that a week ago I stopped the arsenic, no unfavorable symptoms having appeared to this time. Whether the carbolic acid may be considered in the relation of cause and effect, or simply coincident, I am unable to say. The failure of all other remedies and the favorable influence of arsenic in this case, certainly warrants a faithful trial in this painful affection.

—Wendel, *Med. Record.*

Excision of the Gasserian Ganglion.—Mr. William Rose related a case in which he had removed the Gasserian ganglion in a lady, aged sixty, who for years had been subject to most acute neuralgia, first affecting the inferior division of the fifth nerve. He first stretched the inferior dental nerve and divided its mental branches. This gave some passing relief, and he did not see the patient again until March, 1889, when, as she was suffering from severe pain, he trephined the lower jaw and cut away a piece of the nerve trunk. Relief again followed, but in March of the present year her old pain had returned, the right side of the tongue being involved in addition, indicating extension of the mischief to the lingual nerve. He, therefore, cut down upon the inferior dental and lingual nerves in the pterygoid region, through an incision parallel to the zygoma. He observed that he had performed this operation on several occasions at the suggestion of Mr. Victor Horsley. This operation was not very satisfactory, owing to the abundant hemorrhage, but he felt convinced that he had divided and partially excised both nerves in this region. The result of this operation was to produce numbness on the right side of the tongue and integument of the lower part of the jaw. Unfortunately the pain which had occasionally manifested itself in the upper jaw and cheek became greatly intensified. It implicated the alveolar border of the right upper maxilla and extended to the vertex of the head, showing that the superior maxillary division of the fifth nerve was involved. He then determined to proceed to the removal of the Gasserian ganglion, as suggested by his colleague, Dr. Ferrier. He decided to remove the upper maxilla, at the same time—(1) because he believed that there was extensive disease of the nerves in the maxillary bone itself; (2) that the manipulations at the base of the skull would be greatly facilitated by removal of the upper jaw, and (3) in deference to the express wish of the patient that, whatever he did, he should remove what she called the "focus" of her suffering. Accordingly, on April 2, he proceeded to remove the upper maxilla in the usual way, and then, with a skull in front of him to serve as a guide, he inserted the pin of a half-inch trephine into the foramen ovale, and removed a ring of bone, which he handed round. He then caught sight of the Gasserian ganglion lying on the petrous bone, passed an aneurysm needle gently beneath it, and removed it without injuring the dura. The patient suffered somewhat from shock, but on the following day her condition was satisfactory. She, however, complained of heat and pain at the back of the right eyeball, which was very congested. This increased, and resulted in panophthalmitis, necessitating removal of the eye. Her progress in all other respects was very satisfactory. The old pain had quite ceased, and had not since returned. He thought that, in future, when it was necessary to remove the ganglion, this might perhaps be accomplished without removing the jaw. He extremely regretted the loss of the eye, but was disposed to consider it as accidental, and not a necessary result of the operation. As for the patient, she delared that she was now better than she had ever been, and would prefer blindness to the pain she formerly experienced.

—*British Med. Jour.*

Tubercular Peritonitis and Double Pleurisy Resulting in Recovery.—The patient, a youth of seventeen, by occupation a barman, came under my care in Middlesex Hospital, on October 26, 1888. There was an indefinite history of consumption in some relatives on the mother's side, and of a slight attack of ascites with whooping-cough in his own case when only three years of age, otherwise he had always enjoyed good health and been sober. Nine days before admission he began to suffer from some abdominal pain and swelling. The latter condition gradually became more marked, and on admission he was found to have a considerable amount of ascites, the belly measuring thirty-four inches in girth at the level of the umbilicus. His temperature was 100° F., pulse 120, and resp. 24, tongue rather dry and coated. In the chest at both posterior bases there was impaired resonance with diminished vocal fremitus and scarcely audible breath sounds. At the line of commencing dullness on the left side faint friction sounds were present. The area of dullness, especially on the left side, gradually increased for about a fortnight, the friction sound became more marked, he lost weight, and sweated at night. For a few days at first the ascites also increased, the girth of the abdomen measuring thirty-eight inches on November 2, but it soon began to diminish, and by November 13 the girth amounted only to thirty-two and one-half inches. The temperature also at this time was noted to have been normal or subnormal with only one exception, for several days, having previously ranged between 99.2° and 103.2° F. On November 30 the ascites had disappeared altogether, and the pleural effusion was rapidly declining. Coarse friction sounds were heard over the lower half of the left chest, but these soon cleared up, and he continued to make steady progress in convalescence. On January 30, 1889, he was sent to a seaside convalescent home, the abdomen presented a diffused sense of resistance on palpation over its lower half, suggesting matting together of portions of the intestines; while in addition masses of more definite character were felt in the left upper umbilical and iliac regions, and in the right lower umbilical region. After three weeks' residence at the seaside he returned to his work, and presented himself for examination at the hospital on March 13, when it was found that the masses near the umbilicus were less plainly felt than formerly, and that one in the left iliac fossa had disappeared. He had gained ten pounds in weight, and the condition of his chest was quite satisfactory, presenting nothing abnormal except slight impairment of resonance and weak breathing for a couple of inches at the posterior bases. The case was brought forward, not because there was anything unusual in recovery from tubercular peritonitis, but to accentuate the fact that the reverse was the case, recovery being much more frequent than had been commonly thought, especially by the older writers. The statements made by various writers in text-books on medicine were quoted, and statistics given of thirty-five cases occurring in the Middlesex Hospital, of which nineteen were discharged as recovered or relieved. Reference was also made to a paper by Dr. Osler, of Johns Hopkins University, in which a similar view was taken to that put forward in connection with the present case as regards the prognosis in tubercular peritonitis.

—Finlay, *Medical Press and Circular.*

After-treatment of Abdominal Sections.—The entire wound being closed, the ends of the sutures are gathered together in one hand and cut off several inches from the knots. I now proceed to dress the case with my favorite dressing, which consists of:

1. Powdered iodoform sprinkled over the surface of the abdomen, particularly into the umbilicus.

2. Sublimated cotton.

3. Broad adhesive strips of rubber plaster to hold the previous dressing in place.

4. A wide flannel binder, smoothly pinned with safety pins.

To-morrow, at 1 o'clock, or within twenty-four hours, the patient is to have a cup of tea, and she will consider this the best cup of tea that she has ever tasted in her whole life. If she suffers in the meantime from collapse, she is to have sips of whiskey. If she has excessive thirst, she will have enemata of beef-tea.

I trust that she will be able to get along without any opiate, because opium has the effect of stopping the bowels and the other emunctories; but, if she suffers very much, she is to have a hypodermic injection of morphine.

After getting the tea, to morrow, she is to receive, for the first few hours, a dessertspoonful of milk, which is to be administered every hour; and, if it be well received, she will, by nightfall, be able to take one tablespoonful every hour for several hours, and then two tablespoonfuls every two hours. This quantity is to be gradually increased, so that by the end of the third day she will be getting, during the twenty-four hours, as much milk as she can retain and readily digest.

As I mentioned previously, she is to receive no opium, unless it is absolutely necessary to relieve pain, because it has the tendency to stop the bowels; moreover, though it was once considered necessary, after these abdominal operations, to keep the bowels closed for a week or more, such an opinion is no longer in vogue among medical men.

The bowels are to be moved on the second or third day, and the greatest precautions are to be taken in order to prevent any constipation in this case. She is to be urged not to hesitate to pass her wind, no matter who may be present at the time, lest the distended bowels exert a pressure upon the region of the wound, and set up a peritonitis. If she does fill with wind, let the bowels be moved on the second day. For this purpose, I generally order a Seidlitz powder, adding to the contents of the blue paper a dessertspoonful of Rochelle salt. If she vomits, she is to receive large doses of calomel, for the reason that this medicine is heavy, and not liable to be vomited. I give as much as 10 or 20 grs. at once, and repeat it until bowels are moved, having given as much as 75 grs. during the twenty-four hours, feeling sure that at least a part of this heavy substance must have been kept down, however violent the vomiting may have been.

If the flatus be low down in the intestines, and reachable, it is sometimes removed by the introduction into the rectum, or even higher when necessary —into the sigmoid flexure of the colon—of a flexible catheter. In any case, should tympanites or septicæmia become evident, let the bowels be moved. This latter condition is shown by peritonitis; by the pulse rising above 120, and the temperature going above 102° F., when ice is to be applied to the head.

Should obstinate vomiting occur, ice will be given, or sinapisms applied to the epigastrium.

As a rule, it is necessary to catheterize for a day or so after these operations, but it is to be avoided as much as possible, as the too frequent use of that instrument is likely to cause an irritable bladder that is not easily amenable to treatment.

From a week to eight or nine days the primary dressing will be ready to be removed, and the stitches taken out.—Goodell, *Jour. Amer. Med. Assoc.*

GUAIACUM AS A PURGATIVE.—In our thirst for new remedies, there seems to be a danger that some of our good old-fashioned drugs may be forgotten. Take guaiacum, for example. In most of our text-books on materia medica, we are told that guaiacum resin acts as "a stimulant, diaphoretic, and diuretic." I cannot find that there is much evidence in support of this view. Wood, of Philadelphia, seems to be of the same opinion, for he says: "Guaiacum is believed by some to act as a diaphoretic, and to do good by increasing the elimination of the skin; but as I have not been able to obtain—either from medical literature or from the exhibition of the medicine—any distinctive proof of its having any such action to any marked extent, I have preferred to consider the drug as an alterative." Schmiedeberg, of Strassburg, curiously enough, deals with it under the head of "Drugs and preparations used for all sorts of purposes, but now mostly antiquated and obsolete." I am inclined to think that its main action is as a laxative or purgative, and this view is evidently shared by Dr. C. D. F. Phillips, who, in his well-known work on the "Vegetable Kingdom," states that in large doses it produces "dryness in the mouth, burning in the throat, a sensation of heat in the stomach, loss of appetite, heartburn, flatulence, nausea, vomiting, and purging." My attention was drawn to the subject some two years ago, by casually prescribing for a city man suffering from rheumatism some guaiacum lozenges, made up with black current paste. He continued taking them long after the pains had ceased, and his explanation was that they did him good by acting on the liver and bowels. He said that one or two of the lozenges taken in the morning, before breakfast, acted promptly and without inconvenience. I ordered the lozenges for other of my patients suffering from constipation and what is conventionally called "biliousness," and the result was equally satisfactory. The lozenges not being available for hospital use, I had a confection prepared, containing 10 grains of guaiac resin to a drachm of honey. This was curiously popular with the patients, and for the last two years I have used it extensively, not only as a purgative, but in the treatment of chronic rheumatism, sciatica, tonsillitis, dysmenorrhœa, and allied affections. The confection is nasty, but is appreciated by patients. At first I gave it in drachm doses once a day; but they were not satisfied with this, and I had to increase the dose to two drachms three times a day. In this quantity it seems capable of producing the maximum of inconvenience and discomfort, and gives unlimited satisfaction. The purgative effect is very pronounced, and in one case the patient had fifty-six evacuations in the week. In another case it produced a well-marked rash, covering the arms and legs with an eruption which forcibly reminded one of copaiba, That this rash is rare may be gathered from the fact that my colleague, Dr. C. T. Fox, had seen only one similar instance. It was accompanied by intense itching, which disappeared on discontinuing the drug. The guaiacum not infrequently gives rise to a burning sensation in the throat, and to obviate this I prescribed the 10 grains of the resin in half an ounce of extract of malt, which answered admirably. This method of treatment is, perhaps, simply a return to the old-fashioned "Chelsea Pensioner," which consisted of guaiacum, rhubarb, ginger, sulphur, and certain other ingredients; but it is interesting, nevertheless. I am sure that a trial of the guaiacum resin as a laxative or purgative, according to the dose employed, will be found satisfactory. It is possible that if the drug were triturated with cream of tartar,

sugar of milk, or some other equally inert substance, its efficacy would be increased, and it would produce the desired effect in smaller doses.

—Murrell, *Med. Press and Circ.*

Beri-Beri in the Provincetown Grand Bank Fishing Fleet.—In the fall of 1889 I was called upon to attend seven cases, coming from two different vessels.

The prominent symptoms in each case were general œdema, shortness of breath with precordial distress, numbness of the lower extremities with a peculiar shuffling gait, showing marked inability to lift the lower limb at the knee. One case only was confined to the bed, and that was marked by an advanced stage of hydrothorax, dullness on percussion and disappearance of the respiratory murmur, the pulse was weak, irregular and very much increased in frequency, and after five days the patient died with all the symptoms of pulmonary œdema and heart failure. The other cases, after a period varying from two to six weeks, recovered. One man died on the passage home, and the history of the case, as near as I could ascertain, was similar to that just stated. In three cases there was marked enlargement of the spleen; in only one case was there any trace of albumen in the urine, and there was a doubt if that was due to the disease in question. The urine in all was scant, high colored, and contained an excess of urates; there was no retention in any case; the temperature was normal in all; the knee-jerk in two cases was entirely lost, in all diminished; the digestive organs seemed to be but little affected; the appetite was fairly good in the majority of cases; nausea and vomiting were present in one case, but was easily controlled; the bowels in all were constipated, but no more than is usually the case in those that go to the Grand Banks fishing, resulting probably from the kind of food furnished on such voyages, and neglect in going to stool.

The prodromic period in these cases, as nearly as could be learned from the patients themselves, was characterized by general weakness and depression, and an indisposition to work; an œdematous condition of the areolar tissue on the anterior parts of the legs manifested itself, together with severe cramps and pains of a neuralgic character. That the disease was beri-beri there is no doubt, for the symptoms are identical with those described, proving conclusively that the bacteria or septic organism may be produced independent of any earthy or climatic influence, and in a latitude as far north as 45° or 46°.

The undoubted causes of the disease in these cases was defective nourishment; the vessels were poorly fitted for the voyage, the two previous years having been unfortunate ones pecuniarily for the owners, in consequence of which the outfit was cut off in every possible way, the salt beef was of a poorer quality than usual, and the stock of fresh provisions was very meagre. The dampness and cold which is always present on the Grand Banks would undoubtedly act as a factor in developing the disease in a system impoverished and rendered anæmic from a diet of unwholesome food deficient in nitrogenous principles. The catch of fish was at irregular intervals, so that having that article in a fresh state was a rare occurrence. The majority of cases in which this disease occurred were strong, able-bodied men, in whom there were no previous traces of any constitutional disturbance.

Treatment.—Diet seems to form an important part of the treatment of this disease. A mixed diet composed of the coarsely prepared grains, as oatmeal, wheat, etc., with a liberal allowance of fresh beef, in my own experience, is to be preferred. In regard to medication the treatment is rather expectant than specific. Diuretic, and hydrogogue cathartics are indicated when the dropsical effusion is marked; digitalis, to stimulate and control the heart's action. Tincture of chloride of iron and iodide of potassium were also prescribed with apparent benefit.

October 27, 1890. Since writing the above and during the past week about twenty cases of the same disease have been landed here on vessels arriving from the Grand Banks, eleven cases occurring on one vessel out of a crew of thirteen; two of the cases died, with the symptoms as before described, within twenty-eight hours after being brought ashore.

—Birge, *Boston Med. and Surg. Jour.*

Effect of Drugs on the Pulmonary Circulation.—Through the kindness of Dr. Bradford, of University College Hospital, and of Dr. Bokenham, assistant to my colleague, Dr. Lauder Brunton, in the science work-room of St. Bartholomew's Hospital, I am enabled to lay before you the following statements as to the comparative effect of certain substances upon the two circulations. Their researches were carried on entirely independently of each other, and yet their results are practically identical.

Muscarin.—In the *British Medical Journal* for November 4, 1874, Dr. Lauder Brunton gives the following account of the action of muscarin on the heart. Having thoroughly narcotized a rabbit with hydrate of chloral, he commenced artificial respiration, and opened the thorax. Both sides of the heart seemed to be equally filled, the veins only moderately distended, and the lungs rosy. On injecting a little muscarin into the jugular vein, everything at once changed. The lungs became blanched, the left side of the heart became small, the right side swelled up, and the vena cava became greatly distended. After a short time, a little atropine was injected into the jugular vein, and everything instantly returned to its normal condition. The left side of the heart regained its former size, the right side diminished, the distension of the veins disappeared, and the blanched lungs again assumed a rosy hue. Distrusting his own personal observation, Dr. Brunton got two observers who knew nothing about the experiment, and repeated it before them, noting down their observations, which agreed exactly with his own. It is all but impossible, I think, either to doubt the accuracy of the record of this experiment, or to attribute the phenomenon observed, especially the simultaneous distension of the pulmonary artery and the blanching of the lungs, to any other cause than the action of vasometer nerves. Subsequent observers seem to have failed to obtain the striking effects witnessed by Dr. Lauder Brunton, but his account is substantially confirmed by Dr. Bokenham, who tells me that muscarin in a small dose causes rapid fall in the carotid pressure, with, in most cases, a rise in the pulmonary pressure. This rise, however, is not long maintained. The pressure in the pulmonary artery sinks to normal, whilst that in the carotid more slowly rises to its original level. A large dose seems to produce paralysis of the heart and rapid fall of pressure in both circuits.

Amyl Nitrite given by inhalation caused rapid fall in carotid pressure, with simultaneous marked rise in pulmonary pressure. Carotid pressure then rises, and during this rise the pulmonary pressure resumes its original level.

Nitro-glycerine.—In the cat one-fiftieth grain produced a temporary great fall of the carotid, with a slight rise of the pulmonary pressure. When, however, the carotid fall had reached its lowest point the pulmonary pressure also fell. The carotid pressure then rose, but not to the normal figure. At the beginning of this rise the pulmonary pressure showed some tendency to fall, but remained nearly constant. In the dog, one-fiftieth grain produced a primary fall in the carotid, with little or no effect on the pulmonary pressure. A subsequent gradual rise of the carotid pressure then took place, with a very slight fall of pulmonary pressure during the greater part of the rise.

Digitalis.—Digitalin caused steady rise of blood pressure both in carotid and pulmonary arteries, with great slowing of pulse. Tinct. digitalis: In dogs, slight fall in carotid pressure following soon after injection. At this time practically no effect on pulmonary pressure. Following this a steady rise in both pulmonary and carotid blood pressure. Inf. digitalis: In cats, primary rise in blood pressure both in carotid and pulmonary arteries, followed by slight but more permanent rise. (The primary rise here was probably due to the fact that a large quantity of fluid had to be introduced, as the same result followed the injection of a similar quantity of water.)

Tinct. Strophanti.—In cats, a small dose (namely, minim i–ii) produced a primary fall of pressure in both carotid and pulmonary arteries, and a subsequent rise in pressure almost up to normal; heart at same time slow and irregular. A large dose produced first a great rise of carotid pressure, the pulmonary pressure sinking slightly at first and then rising slightly. Then great quickening of heart with steady fall of pressure in carotid; the pulmonary falling to, but not below, its original level.

Ergot produces primary rise in pulmonary, with simultaneous fall in carotid pressure. This rise, however, is of short duration. Subsequently both pressures rise.

Aconite produces fall in pressure in both carotid and pulmonary arteries.

Strychnine, in bote carotid and pulmonary arteries, produces a rise in pressure, especially marked in the pulmonary.

Chloroform.—Both pressures fall together.

Ether.—Both pressures rise together.

Atropine (*Sulphate*) produces first a steady fall in carotid pressure, the pulmonary sinking at the same time, but in much less degree. During this period the heart is slowed, and the vagus nerve is excitable. Next pressure rises in both, and pulse becomes more frequent, the inhibitory power of the vagus being gradually abolished. When the pressure reaches its highest point, the heart cannot be stopped by stimulation of the vagus, and a second dose of atropine will have no further effect.

Quebracho (*Tincture*) produces in carotid a primary fall, in pulmonary a slight rise, followed in the carotid by a steady rise to a higher point than normal, whilst in the pulmonary artery the higher level already reached is maintained; finally, in the carotid the pressure becomes very great, whilst in the pulmonary artery it does not rise above the slightly higher level it reached at first.—Andrew, *Provincial Med. Jour.*

PENZOLDT states that the occasional failure of orexin may be explained by the insolubility of the coating on the pills. The drug should be used in wafer.

Medical News and Miscellany.

DR. D. E. SALMON has been assigned, by the Bureau of Animal Industry, to arrange for the inspection of meat in Chicago.

A PHARMACEUTICAL chemist of Woronesh, in Russia, has been condemned to six months' imprisonment for selling adulterated quinine.

GENERAL BOOTH, in his book, "In Darkest England," says: "Out of every five persons in London, one dies either in the hospitals, asylums or workhouses."

DR. BOSWELL GORHAM, of Lexington, Ky., was shot and killed on November 11 by a colored farm hand. Dr. Gorham was fifty-five years old, and had retired from practice for some years. During the war he was a surgeon in the Confederate army.

THE work on "Psychology," on which Prof. William James, of Harvard University, has been engaged for many years, and which is expected to give the most complete study yet made of that science, will be ready for publication in the early part of 1891.

AN epidemic of typhoid fever is raging in Clementville, Ohio. There have been eighty-nine cases, twenty-five of which have proved fatal. At present forty persons are suffering. Business has been suspended. The place has a population of two hundred.

THE Southern Surgical and Gynecological Association, in session at Atlanta, elected the following officers for 1891: President, Dr. L. S. McMurtry, of Louisville, Ky.; Vice-Presidents, W. Gastohe, Atlanta; Dr. J. T. Wilson, of Sherman, Texas. The terms of Dr. W. E. Davis, of Birmingham, Ala., as Secretary, and J. H. Cochrane, of Birmingham, as Treasurer, were continued. The only change in the Judicial Council was the substitution of Dr. George J. Engelman, of St. Louis, for Dr. Bedford Brown, of Alexandria, Va., whose term expired.

DEATHS last week numbered three hundred and sixty-seven, an increase of nineteen over the previous week, and three less than during the corresponding period last year. The principal causes were: Apoplexy, 13; Bright's disease, 7; cancer, 10; casualties, 9; congestion of the lungs, 6; consumption of the lungs, 53; convulsions, 13; croup, 12; cyanosis, 5; debility, 7; diphtheria, 21; disease of the heart, 30, scarlet fever, 5; typhoid fever, 12; inflammation of the brain, 9; inflammation of the bronchi, 8; inflammation of the kidneys, 5; inflammation of the lungs, 38: inflammation of the peritoneum, 6; inflammation of the stomach and bowels, 8; inanition, 6; marasmus, 10; old age, 10; paralysis, 6.

THE Board of Health of Philadelphia has recently made the following important changes in the rules regulating interments:

Rule 242. (a.) No interment of the dead body of any human being, or disposition thereof in any tomb, vault or cemetery, nor the removal of any body from the city for interment elsewhere, shall be allowed, without a permit therefor be granted by the Board of Health upon presentation of the certificate of death; and no sexton, superintendent, or other person shall assist in, or assent to, or allow any such interment, or aid or assist about preparing any grave or place of deposit for any such body for which such permit has not been given authorizing the same. Every cer-

tificate of death must be signed either by a physician, the coroner, or health officer, to which must be appended the certificate of the undertaker.

Rule 242. (k.) No body of a person who has died of any of the following diseases, viz.: Asiatic cholera, yellow fever, cerebro-spinal meningitis or spotted fever, small-pox or varioloid, diphtheria, relapsing fever, typhus or ship fever, and scarlet fever, shall be placed in an ice-box, or be removed from the city of Philadelphia, except for the purpose of interment in the adjacent rural districts, and such removal shall not be made by public conveyance, and in all such cases the body shall immediately after death be completely enveloped (and remain so enveloped) in a sheet saturated with a four per cent. solution of chloride of lime, or a five per cent. solution of pure carbolic acid, or a one-tenth per cent. (1 : 1000) solution of corrosive sublimate, and be encased in a coffin or casket, the entire inner surface of which shall be thoroughly and completely lined with a layer of raw cotton of a thickness of not less than one inch; and said coffin or casket shall be tightly closed with screws, and remain so closed; or the body, wrapped as above, shall be encased in a coffin or casket of metal, with all joints and seams closely soldered. Burial to take place within thirty-six (36) hours.

A STRANGE experiment is in progress at the Charity Hospital, on Blackwell's Island. Dr. Phelps, of the University Medical College, assisted by other physicians, is trying to graft upon the deformed leg of Johnny Gethins, a fourteen-year-old boy, the leg of a spaniel dog. Boy and dog are bound together, and the dog is incased in a plaster cast, so he cannot move. The surgeons think they can make the strange graft and give young Gethins a sound leg, so that he can throw away his crutches, or, rather, transfer them to his dog.

AN EXAMINATION ECHO.—A medical student was undergoing an examination.

"How would you make a patient transpire?" demanded the professor.

"I should employ sudorifics, such as tea, coffee, and other aromatic warm drinks."

"But suppose these should not produce the desired effect?" queried the professor.

"Well, in that case," said the student, "I should use the volatile oils, such as ether and the various compounds of alcohol."

"But suppose these should not answer your purpose?" asked the professor.

"I should use triturated antimony, James' powder, or Dover's powder," replied the student.

"But if all these means failed?" remarked the professor.

The student was sweating great drops.

"I should take sarasparilla, bitter sweet, or saffron, jaborandi."

"And if even all of these did not act, what then?" queried the profesor.

"Then I would sned the patient to you to undergo a medical examination," sighed the student.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

LOCK BOX 76, WASHINGTON, D. C.

Army, Navy and Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from November 4, 1890, to November 10, 1890.

By direction of the Secretary of War, Colonel Basile Morris, Surgeon, and Major George M. Sternberg, Surgeon, are appointed members of a board of officers appointed to meet, at the call of the senior officer thereof, in San Francisco, California, to examine such officers of the Corps of Engineers, as may be ordered before it, with a view of determining their fitness for promotion, as contemplated by the Act of Congress, approved October 1, 1890. Par. 5, S. O. 261, A. G. O., Washington, D. C., November 7, 1890.

By direction of the Secretary of War, Lieutenant-Colonel Charles T. Alexander, Surgeon, and Major Johnson V. D. Middleton, Surgeon, are appointed members of a board of officers, appointed to meet at the call of the senior officer there at the rooms of the Board of Engineers, Army Building, New York City, to examine such officers of the Corps of Engineers, as may be ordered before it, with a view to determining their fitness for promotion, as contemplated by the Act of Congress, approved October 1, 1890. Par 4, S. O. 261, A. G. O., Washington, D. C., November 7, 1890.

By direction of the Acting Secretary of War, leave of absence for four days is granted Captain William D. Crosby, Assistant-Surgeon, U. S. Army. Par 2, S. O. 259, A. G. O., Washington, D. C., November 5, 1890.

Captain Louis A. LaGande, Assistant-Surgeon U. S. Army, detailed as member of board for duty in connection with the World's Columbian Exposition, and will report by letter to Major Clifton Comly, Ordinance Department, member of the board of control and management of the Government exhibit to represent the War Department. Par. 1, S. O. 260, A. G. O., Washington, D. C., November 6, 1890.

Leave of absence for one month is granted Lieutenant-Colonel Dallas Bache, Surgeon U. S. A., Medical Director, Department of the Platte. Par. 6, S. O. 82, Dept. Platte, Omaha, Neb., November 1, 1890.

Clinical Lecture.

INTRODUCTORY LECTURE UPON OBSTETRICS.

BY JESSE HAWES, M.D.,
GREELEY, COL.,
Lecturer upon Obstetrics, University of Denver.

GENTLEMEN: Only one parturient woman in twenty will urgently need your skilful aid; but the remaining nineteen will give you, for your intelligent council, for your words of cheer and sensible sympathy, and for your minor aids a wealth of gratitude and affection; yea, of substantial pecuniary reward, such as will not be given you by any other class of patients for any like amount of professional work. The truth of the first statement you will learn from the carefully-kept records of the great obstetric hospitals of Europe and America. The other truth you will learn from your own sweetly-treasured memories of the past, as in the future years you recall the lessons of your busy professional lives. To you, as general practitioners, the field of obstetrics will be one of deep interest. I desire, in this introductory lecture, to briefly scan the subject of obstetrics from the standpoint of the historian, and, to a slight extent, from the standpoint of the analyst. Let us look back from the commanding point furnished by these last years of the nineteenth century—these years of many books and much research; let us note the customs of primitive people in their obstetric procedure; let us watch the progress that centuries have brought, and, if we are attentive observers, we shall more highly appreciate the exalted position which this science has honestly earned.

The history of obstetrics may properly be divided into two periods—the primitive period and the scientific period. The primitive period extends from prehistoric times down to the year 1550, and, fortunately for our study, illustrations of primitive practices may be observed to-day among the primitive people of both hemispheres. The scientific period is measured only by the last three hundred and fifty years.

In the first period, the practice of obstetrics was empyrical, not based on anatomical and physiological knowledge; largely governed by intuition—often controlled by religious dicta; but slightly influenced by scientific reasons—though many of the practices taught by instinct are in accord with reason. The beginning of the second period dates from 1550, because at that time podalic version—*i. e.*, the changing of some less favorable presentation to a foot presentation—was re-discovered, and never again lost to sight. Podalic version had been discovered, taught, and practiced, more than one thousand years before, but for several hundred years had completely disappeared from the knowledge of obstetric practitioners. For more than one thousand years previous to 1550, no essential progress had been made in obstetrics, while many and valuable improvements appeared shortly after.

In the study of the first period, we are indebted to ethnological research, for this has aided greatly to lift the veil of mystery and cast the light of explanation upon the scanty records of the distant past. The customs of primitive people to-day, when removed from all contact with civilization, reflect the practices of the primitive people of all times, even back to the early morning of humanity. In the study of the second period we begin by delving among the musty tomes of the sixteenth century—hunt through the medical museums of Europe and America, reading the obsolete works treasured as curiosities in the great libraries of the world, diligently perusing the scattered current literature of the past two centuries, scanning the thoughts of the investigators, leaders, and teachers of our profession as they grow clearer and brighter, until we stand in the great light of the present day, intensely expectant of the still greater

boons our science shall give to the daughters of Eve who shall be the mothers of the twentieth century.

First, let us consider the primitive mothers of the human race. (So little space is given to this phase of obstetrics in standard works, that I trust it may interest you if I devote much of the present hour to it.) The condition of parturient women among these simple people was by no means as cheerless as might at first thought appear; they were pleased at the prospect of maternity; it was one of the few eventful periods of their uneventful lives; they became objects of more importance and solicitous interest to the leaders of their tribes. Sarah, the wife of Abraham, laughed when assured that she should be blessed with a son; so many years of sterility had become a mortification to her. Isaac, for himself and his wife, entreated the Lord that Rebekah should not be barren. Rachel cried out in agony, "Give me children or I die!" Moses told the children of Israel that they should be blessed above all people, and the first blessing he mentioned was that "there shall not be male nor female barren among you." The same spirit is apparent among the artless and unaffected primitive people of to-day. The Andamanese wives are extremely proud of their condition when "coming events cast their [substantial] shadows before." In their native state this is, of course, very evident to any beholder, and if a stranger shows himself in one of their villages, the envied wives hasten to pass before his tent, dressed in their summer costume of a parasol, wearing a modest fig-leaf and a smile. They are envied by their sisters; they know it; they delight in it, and in its cause. Not only do primitive people in this condition feel themselves of more than passing interest to their tribes, but they believe that good and evil spirits are following their tracks as closely as previous engagements will permit. Among some of the Finnish tribes females *enceinte* change their shoes weekly. This is done to throw the pursuing evil spirits off the scent, to mislead them, as they are supposed to follow for the purpose of seizing the newborn child. Up to the present time they flatter themselves that they have always outwitted the spirits of evil—there is much mischievous pleasure in this.

The respect entertained for the mother of children, is not confined to the people of humble surroundings. Madam De Stael asked the Great Napoleon, who, in his opinion, was the first woman of France, "She who is mother of the most children" was his answer. The student of the history of that time will see more in the reply of the Emperor than appears on its surface. Labor was and is, among primitive races, more often normal than among their more enlightened sisters; there were fewer cases of deformity of the pelvis among them.

Deformity of the pelvis is a product largely of crowded rooms, vitiated atmosphere, and poor living. With less crowding, there was also less danger from infection. Secluded from other races by their imperfect means of travel, women in primitive times maintained a purity of type that was favorable to normal labor. The amalgamation of races produces a disproportion between fœtal and maternal parts. The head of the mulatto child is relatively large for the negro mother. They had less of worry than their sex in civilization—they knew nothing of the advantages of scientific obstetrics; hence, ignorance to them was bliss. Much of the gloom of this world, gentlemen, comes from coveting the better conditions enjoyed by others.

We can readily account for the rapid and easy delivery of savage women who live in a natural state, and the rarity of accidents from these facts: They marry only their kind, and thus the proportions of the child are suited to the parts of the mother; their out-door lives give healthy conditions and vigorous frames, and the activity of their lives was favorable to head or breach presentations. Primitive people have nearly always held the child largely responsible as to the time at which labor should occur; they believed it selected its own position in the uterus, and left its first home only when it chose to do so.

The more ignorant Chinese believe that pregnancy can last two or three years, because the child does not wish to leave the womb; they place stress upon the voluntary actions of the child. In a legal Mussulman treatise it is stated that the maximum of gestation may attain four or five years. M. Corre tells us that even in France the time is not long passed when the voluntary motions of the fœtus, and when the cause of labor pains and expulsion of the child was looked for in the desire of the fœtus to change its condition of life. It is quite a source of complacency to the savage parturient that the fœtus must assume his full share of responsibility. Among the Pah Utes they endeavor to make the journey of the little stranger to his extra-uterine home easy and expeditious, with the least possible pain to the mother. They consider the sojourn of the offspring *in utero* as a voluntary matter, and after a given length of time, say nine moons, the child is to be starved out of its maternal quarters, as a wood-chuck is forced from its hiding place; hence, for weeks before the expected event a partial fast begins with the mother, which becomes almost absolute as the time approaches, so that by the end of the allotted period of gestation the fœtus will not only be ready, but anxious to come to the world in order to reach the supply of milk which the mother has now in waiting for the child starved in the womb.

When we study the custom of savage races at the confinement, we find a wide range of usages. In the Sandwich Islands the confinement is witnessed by all who happen to be about; this is not objectionable to the patient. The same lack of privacy prevails among the Mohammedans of India. They prize the occasion as an opportunity for display that must not be neglected. Yet, with all these facts in her favor, the primitive woman, about to become a mother for the first or twentieth time, does not always find her path strewn with roses, nor her couch a flowery bed of ease.

In Ceram, an island north of Australia, they tie the patient to a tree or post, with her hands above her head, and she is not released until the child is born, or the spirit has left the body of the mother.

Dr. Choquette says, that two or three years ago an Indian party of Flat Heads and Kootenais, men, women, and children, set out for a hunting trip. On a severely cold winter's day, one of the women, allowing the party to proceed, dismounted from her horse, spread an old buffalo robe upon the snow, and gave birth to a child, which was immediately followed by the placenta. Having attended to everything as well as circumstances permitted, she wrapped the young pappoose in a blanket, mounted her horse, and overtook the party before they had noticed her absence. Not a very agreeable experience. When, among these people labor was unduly prolonged, their prospect for the immediate future was not joyous. The Mexican parturient woman seizes a rope tied to the beam or rafter, while her friends encircle her abdomen with their arms, and with each pain

drag downward, with the weight of one, and sometimes two or more persons. In some Indian tribes a male assistant stands a-straddle of the patient, over her buttocks, his hands clasped around her waist; during each pain he pulls upwards, thus making pressure on the abdomen. The Modocs are always delivered in this position. Among the Brule Sioux, during the expulsion of the fœtus, the squaw stands erect, with her arms about the neck of a stout male supporter; the strong, young, unmarried bucks are most frequently chosen for this service.

The Sclavonians, who are not unlike some of our Indians, endeavor to shake the child out of the womb in cases of prolonged labor. A physician of Pueblo, Colorado, informs us that the lower orders of Spanish women always take the kneeling position, and if the placenta is tardy they always drink a cupful of soapsuds, which produces vomiting, followed by the immediate expulsion of the afterbirth.

In Kabylie, if the labor is slow, an assistant butts the patient in the abdomen with his head. This is esteemed among them much as civilized races regard a consultation of three solemn doctors. In New Caledonia, they use violent pressure and blows of the fist upon the abdomen, in hard labor. Among the negroes of New Guinea, when labor is much prolonged, the friends of the woman cheer her by beating or kicking her in the stomach. In Senegal, practice is less heroic; some one sits upon the patient's abdomen. The Loangos even tramp upon the abdomen as one of the last resorts. In severe labors, the Kalmucks procure a number of men, provided with guns, place them in hiding near the bed of the patient; as soon as the midwife perceives the head distending the perineum she signals the men who fire simultaneously, thinking to assist nature by the sudden fright which the noise must cause. Dr. Forwood narrates a similar practice among the Comanches; a woman who experienced a very difficult labor was brought out on the plains, and a noted warrior, mounted on his fleetest steed, with all his war paint and equipments on, charged down on her at full speed, turning aside only at the last moment when she expected to be pierced through the body and trampled under foot. This terrible ordeal is said to have been followed by the immediate expulsion of the child. The Baschkirs rely upon their "devil seer," who discovers the presence of the evil spirit and drives him away, if rewarded by the present of a sum of money or a fat sheep. These honestly credulous people have a faith as strong and abiding in a good devil seer as the faithful Christian scientist has in the power of Mrs. Eddy.

Among others a priest is called who hastily mumbles a few verses of the Koran, spits into the patient's face, and leaves the rest to nature. . . . The Crow Indians, of Montana, give their squaws a villainous drink made from a wild tobacco plant, In ancient Mexico, if the pains were too severe, the patient was given a small piece of the tail of an opossum, carefully rubbed down in water, and the following prescription is on record as having been given by the court physician in Siam to a lady of high rank at the time of her confinement: "Rub together shavings of sapon wood, rhinoceros' blood, tiger's milk, and the cast off skins of spiders." Notwithstanding all these remarkable aids, some labors will not terminate; a presenting shoulder, or some malformation of the mother or child prevents all progress. The child is charged with the fault, and the mother is made co-defendent for being the mother of such an infamous character, who would probably bring nothing but evil to his people and tribe. This is philosophical; when death comes to mother and child, this view of the case relieves relatives from the discomfort of mourning their loss. Why should they mourn over the death of such a villainous character? they believe he could easily have escaped from the uterus if he had not voluntarily placed himself in a malposition. A large per cent. of primitive people take this comfortable view of such cases.

. . . . . .

After the birth of the child, what was the experience of the primitive woman?

It is safe to reply that the evil genius of superstition and ignorance was, not always, but too often, her guardian. Wild and rude races have always sought their habitations near lakes or the waters of a running stream. Among many tribes the confinement of the female occurs upon some secluded bank of this stream. As soon as the patient has been delivered of her offspring she plunges into the clear water; often with her infant in her arms, and carefully bathing her body, cleanses herself from the impurities incident to the occasion; a very common sense method of securing asepsis to these hardy individuals Among our Sioux tribes the squaw belt is almost universally applied as soon as labor is completed. This is a belt of leather, four inches wide, and furnished with four buckles. Its object, among the Sioux, is to gather in the redundant tissues of the abdomen, squeeze the emptied uterus, assist in expelling the placenta, and prevent excessive loss of blood by its compression. Among the Apaches, it is deemed very essential that, as soon as the placenta is expelled, the woman should be kept on her feet, walking about for half an hour or more, so as to favor a free discharge of all blood and prevent its coagulation in the womb. The same custom is observed among the Dakotas, the Flat Heads, and other Indians of the Pacific coast.

. . . . . .

The Kiowas, Comanches, and Wichitas use a broad bandage of buckskin, similar to that of their neighbors, the Sioux. This is worn for about a month.

In this connection, it is proper to state, that among some wild people custom demands that a merited punishment should be visited upon the husband as the cause of so much suffering. Among the land Dayokas of Borneo, the husband is always treated badly after the birth of the child. He is given only rice and salt to eat, and is denied enough water to quench his thirst, and for several days is forbidden to bathe, or show his face out of doors. Among some of our Indian tribes, the father, after calling his relations and friends together, and having a feast of boiled dog and other Indian delicacies spread for them, goes off and hides himself until the child is a week old.

This practice, however, is only observed by the young men; these are so ashamed of their part in the affair that they go to some sympathetic friend, and stay until they can summon sufficient courage to come back; then the wife presents the child for the first time to its father. I need not inform those gentlemen who have lived among them that the old Indian is never ashamed of anything.

In Old Calabar, the husband is clothed like a woman, put to bed, and sighs terribly, as if he were enduring great suffering. A similar custom formerly existed in Greenland, and still prevails in Guiana, among certain Canadian tribes and the Caribbeans: while the woman who has been delivered attends to her household duties, her husband goes to bed, and receives in her place the visits of condolence from friends and relatives. This peculiar comedy is as

likely to be due to laziness on the part of the "buck" as to the purpose (alleged by some) of causing the woman to forget her trouble, and give her an innocent revenge for the suffering which she alone has supported in the work of reproduction.

The influence of religious beliefs shows itself in the customs and teachings of many primitive people. In ancient Athens, it was sacrilegious for a woman who had not born children to be a midwife; and she must have passed the menopause. In passing, we may mention that among the ancient Greeks, men were not prohibited from performing the part of midwives, but such men were called mæutai (man grandmothers). There are man-grandmothers (old grannies) practicing obstetrics in America to-day.

The mythology of the Romans is rich in gods and goddesses who presided over particular phases of labor. Juno and Diana Lucina presided over labor in a general sort of way; they were consulted as the deities of general practice; they made no pretensions as specialists. Virgil sings to us of Prorsa, who was an assistant to Lucina, and was called upon in cephalic presentations. The goddess Mena made a specialty of the monthly flow and lochia. Then there were goddesses for post-puerperal women; goddesses for the infant in the cradle; goddesses for the infant in the act of nursing; goddesses for the development of the body. The influence of all these specialists upon the practice of obstetrics is apparent as we study the history of the subject. Gods or goddesses, genii or ghosts, spirits, elves, fairies, brownies —left their impress upon the customs of the primeval people of every clime. The subject is interesting and curious, but it is too broad for us to compass.

At length, as man became more enlightened, a knowledge of instruments that might be of use in assisting the mother to terminate her labor, is apparent; hooks, knives, fillets, perforators. Later, a crude knowledge of anatomy appears, but the professional lore which was the property of Greece, and afterward of Rome and her dependencies, was buried in the monasteries when Rome, rendered effeminate by her wealth, luxury and vices, staggered and fell under the blows of her barbarian assailants.

For nearly ten centuries the years are known in history as the dark ages.

Sight began to dawn in Western Europe in the thirteenth century; one body, in five years, was allowed and ordered for dissection in the University of Salerno.

In the fourteenth century the study of anatomy was permitted at Montpelier, and at the Universities of Prague, Vienna, and Tubingen in the fifteenth century.

But the practice of obstetrics profited but little from the knowledge thus gained; the knowledge of anatomy was monopolized for surgery. Obstetrics was almost wholly in the hands of ignorant midwives; the surgeon was only called in to cut away the fœtus.

Law and public sentiment decreed that women in ordinary labor should be attended only by women.

Dr. Wertt, of Hamburg, determined, in 1520, to study the phases of natural labor. He clothed himself in woman's garb, and made his way to the lying-in room; he was detected, and burned alive for his profane temerity.

A hundred years after, not far from the time when America was settled by the English, Dr. Willugby, to assist his daughter, who was a midwife, was obliged, by the popular prejudice against men as obstetricians, to crawl on his hands and knees into a dark room to aid a suffering patient.

These illustrations of the statics of obstetrics, you will note, are located in Germany and England. France, the birthplace of scientific obstetrics, was, for nearly two centuries, in advance of other civilized countries.

During the remainder of our hour we shall briefly scan the second period—the period of scientific obstetrics.

The most striking feature of this period is the effort to preserve fœtal life.

Podalic version was re-discovered, by Ambrose Pare, in 1550. Stop a moment, and note what version implies.

Among the Arabians, in their best obstetric days, if an arm presented, they simply cut off enough to permit the head of the child to be drawn down to take the place of the amputated arm. This meant almost certain death to the child, and often, on account of the rude instruments used, death to the mother.

In Europe, if a leg presented, haste was made to push it back, and the woman was tossed in all ways, her head downward, to see if perchance the head of the child might not take the place of the leg. This failing—amputate the leg (Rhodian). Result—death to child, certain; to mother, probable.

Hippocrates, nearly two thousand years before, taught that the child could not be born otherwise than head first; aud his teachings were still respectable authority.

Podalic version meant saving the life of the child, where heretofore it had been lost; it also meant saving the lives of many mothers.

The next important advance was the discovery of forceps in 1647, a hundred years after the discovery of podalic version.

The forceps were the legitimate succors of the hooks; they were not, however, the lineal decendants of the hooks. The hooks meant death to the child; if not dead before their application, he died shortly after.

The forceps were a notable example of the life-preserving characteristic of the second or scientific period. I need not enter into a history of the forceps; simply to note their great value over any instrument that had preceded them is sufficient for this occasion. The first forceps were straight; they did not conform to the curve of the pelvis; they were of value when the head of the child was well down in the pelvis; they were dangerous when the head was high. The lives of many children, the lives of many mothers, could be saved if the forceps could be so moderated in form as to admit of their being passed through the superior strait. It was a hundred years after the discovery of the straight forceps before the pelvic curve was added. This modification of the form of the forceps was a great boon to humanity.

Until 1550 there had been no accurate description of the normal pelvis; and for nearly two hundred and fifty years there was but little profitable study given to the physiology of obstetrics. From 1800 to nearly 1850 was marked by the great advance in this direction. Three years before 1850 chloroform was discovered. There has never been a discovery that can do so much to diminish the pain of woman in the sharp agony of labor. I have administered chloroform in hundreds of cases. Properly administered, I believe it one of the least harmful of medicinal agents. I cannot name a half dozen of those who have experienced its blessings who would willingly pass through a subsequent labor without it. "What, doctor; am I all through? Is my baby born, and I

did not know it? I suffered nothing; I have slept sweetly all the time." How many, many times has this salutation come to me from a heart full of gratitude!

Never until your own dear ones are sufferers, and never until you have learned to properly administer chloroform, and learned how harmless it is in obstetric practice, can you appreciate a tithe of its great value!

Chloroform, not ether, is the obstetric anæsthetic. Properly administered and properly supplemented, I believe it is in labor one of the least harmful and one of the most beneficient of all of a good God's gifts. Ergot, as an oxytoxic, was not used until the beginning of this century. It has saved many lives. Learn to use it properly; it belongs to the age of scientific obstetrics.

There is a method of version designated as the Hicks method, in honor of the eminent English obstetrician, Braxton Hicks. In a moderate percentage of cases it can be utilized; it is, for the mother, a conservative procedure; it is a method, the discovery and perfection of which, should immortalize the discoverer. By this method it is possible to perform version without introducing the arm or hand into the uterus. Dr. Hicks published his paper upon the procedure in 1860; and the world has honored his name and the method by associating both together. The same method was proposed six years before by an American physician, Dr. Wright, of Cincinnati. Dr. Wright's article was honored by the gold medal of the American Medical Association. The same method was also taught in 1807 by Wigand, of Ham burg, and then completely forgotten. For their own fame the two last named gentlemen published the method too early—the world was not ready to appreciate their genius; but the discovery made, independently as it was, is an ornament to the scientific period of obstetrics.

It is only within the last fifty years that the profession has fully recognized the infectious nature of child-bed fever; the knowledge has preserved the lives of thousands of mothers. The use of viburnum prunifolium as a preventive of abortions has saved thousands of lives; its blessings have been given to the world within the last fifteen years. Cæsarian section has been practiced, perhaps, from prehistoric times. Through all the ages it has been to the mother a dangerous, almost necessarily a fatal last resort.

It was a measure proposed largely for the child, much less for the mother. The antiseptic methods of this wonderful scientific period have performed modern miracles. A miracle performed nineteen centuries ago, called the dead from the grave; the modern miracle of Cæsarian section skilfully performed, properly supplemented, saves nineteen out of twenty from entering the grave through parturition. According to the latest statistics Cæsarian section performed by skilful operators gives a mortality of only five per cent.

The leaders in our branch of medicine and their great achievements are myriad; we, at this time, cannot even name them, but the men and their wonderful works are known to progressive and studious members, young aud old, of our profession, their influence is felt, their teachings are practiced, in the smallest hamlets of the civilized world; better obstetric service may often be obtained in the wildest mining mountain town of Colorado to-day than could be expected in the great hospitals of Europe fifty years ago. We are to-day in the midst of a most brilliant era; one pregnant with great promises for the future. Another thought, more important to each of you personally than any we have dwelt upon. To you, the unassuming students of to-day, the future will be, must be, committed. The students of to-day must inherit the future; there are no other heirs. Fortunate is he, who early in his professional life, recognizes the certainty of his inheritance and its majesty. Your responsibilities will be great; your opportunities will be great; let your achievements be great.

The habit of industry; the habit of study; the habit of conscientious professional work; all these, acquired early and maintained through your professional lives, will make you the great physicians of the great future.

PLACENTA PRÆVIA, WITH NOTES OF CASES.[1]

By A. F. MYERS, M.D.,
BLOOMING GLEN, PA.

GENTLEMEN:—I have nothing new to bring you; no particular doctrine to expound, nor favorite theory to advocate. You are all familiar with the perplexity of the subject and its high rate of mortality in whatever method of treatment employed. I endeavored not to be too radical in my procedure, nor did I wish to follow the expectant mode of treatment; the happy mean was my design, and how I succeeded is for you to judge. I invite your attention to the following cases, as I noted them at the time.

CASE I. Mrs. D., aged thirty-six, multipara; sixth confinement; in her ninth month of pregnancy. Our worthy member, the late Dr. D. P. Moyer, was called December 21, 1886, at 6 A. M., and found the patient in labor, having shortly before, as she stated, passed a half chamber full of blood. The doctor made a careful examination.

Diagnosis—Placenta prævia.

With implicit directions to remain quiet, he left the patient, and came to my office and requested me to take charge of the case. In one hour after he left the patient I saw her. I found the patient greatly alarmed from the loss of blood sustained. She was weak, with anemic countenance, but pulse rate normal; no labor pains. The history of the patient was that all former labors were natural; general good health; that she had had a number of slight hemorrhages at different periods for a month or more, but of no great quantity. Little attention was paid to the matter, assuming it to be merely incidental to her condition at this time. The patient felt the movements of the child. Carefully auscultating the abdomen, the fœtal heart sounds were not very distinct, yet audible. Digital examination revealed a long, soft, flabby cervix, sufficiently dilated to admit the index finger to ascertain the true condition of affairs. The placenta was implanted near the internal os uteri, and could be easily distinguished. I could fully confirm Dr. Moyer's diagnosis. My examination dislodged several clots of blood in the lower segment of the uterus, and a profuse loss of blood followed. I had all the pillows removed, and head lowered to a level with the nates. Stimulants, such

[1] Read at the annual meeting of the Bucks County Medical Society at Doylestown Pa., November 5, 1890.

as whiskey and ammonia, were regularly administered from this time on with good results. I did not risk to leave the patient, but remained in constant attendance, noting every advance. In my estimation her anemic condition would admit of no delay, so I decided upon three things—tamponing, dilatation, and delivery as soon as the condition of the os would admit. I proceeded to plug the cervix with tampons made of pledgets of cotton and pieces of muslin, saturated with vinegar, for the want of something better, with a view of checking the hemorrhage and to assist in dilating. In about three hours this hastily improvised tampon came away. I replaced a similar one, which remained some time. At 2 P. M. this was again dislodged, and more blood was lost. The os was now dilated to the size of a dollar. At regular intervals I emptied the bladder by means of a catheter, so as to avoid placing the patient on a vessel, and possibly disturbing the packing. If I had possessed a good rubber dilator I would have used it at this time. Again plugging the os and packing the vagina more completely, which remained for three hours, when slight labor pains became manifest. At this point I suggested the use of an anæsthetic and assistance, but to this plan the friends demurred. They did not wish the child to be deprived of a chance of living, and as long as it was living I should not sacrifice it unless there was no other alternative to insure the safety of the mother. At 7 P. M. the flow again became more serious, the pains increasing in severity, and the os dilated to possibly three-fourths, and now more rigid. Bleeding occurred at intervals, and my tampons were of no avail. An attack of syncope came on, but the patient soon revived. I determined to accelerate labor at all hazards, and, accordingly, I passed my right hand carefully into the vagina, completely plugging the orifice, and in this manner I greatly assisted nature with my fingers at dilating the rigid os. I felt the placental mass all about the mouth of the womb, as far as I could reach then, and concluded I had a placenta prævia centralis to deal with. I tried to make an opening through the mass with my fingers, but failed after working at it for a quarter of an hour. Placing my left hand upon the abdomen, I steadied the uterus, pressing it down and gently forcing a little at dilation, I got my entire hand within the womb in endeavoring to detach the greater portion of the placenta. I gained another point; I, however, could barely reach its margin on the mother's left side, but, hooking it with my fingers, I crowded it to the right side. During this procedure another alarming syncope took place. I increased the stimulants, and in a few minutes the patient revived. The os was now sufficiently dilated, and, pressing the fœtus down upon the superior strait as much as possible, and with my fingers pressing the amniotic sac against the presenting object, I ruptured the membranes in this manner. I could now for the first time determine the presentation, and found the breech entering the superior strait. The patient being greatly exhausted, and by her request to desist, I made no attempt at bringing down the feet. Bleeding was now almost stopped. Pains became more regular, but of short duration. At 10 P. M. I was unable to hear the fœtal heart sounds, nor had the mother felt any movements for the last hour. Nature seemed unable to perform her task, and, the patient being so exhausted, I again assisted. The breech being now fully engaged, and taking one of the blades of my forceps, I passed the handle up and hooked it back of a leg. Suspecting the non-viability of the child after another careful examination, I used considerable strength in making traction. The breech was born in a few minutes, but both arms were extended up at the sides of the head, wedging it completely in the bony cavity. They were brought down with some difficulty and more loss of blood, but the head soon followed, and a dead female child was ushered into this world just as the midnight hour passed by. The cord was loosely lapped about its neck; the placenta soon followed without any assistance, and hemorrhages ceased. No laceration of parts occurred. Examining the placenta I found that I had almost penetrated the mass a half inch from its centre. The patient made a slow but complete recovery.

This case is one of frequent occurrence. Is is of a class that is often difficult to decide what course to pursue to reasonably insure the safety of the mother and at the same time give the child a possible chance of living. There is a grave responsibility thrust upon the accoucheur that can neither be shirked nor shifted. He must be equal to the occasion. The emergency of the case requires his undivided attention. The objections of the parents to the induction of premature labor must be met. Frequently they will fail to see the necessity of such a formidable procedure, and the attending physician will have some difficulty in convincing them of the necessity of such a course; however, he will find by waiting and repeated hemorrhages he has jeopardized his patient's life to an unwarranted degree, with nothing but a fatal termination momentarily staring him in the face. You may reason, gentlemen, that if the patient will not accede to the plan proposed, which you deem absolutely necessary for her safety, that you would be justified to immediately sever your connection with such a case, and retire. What would be profited by it? The good name and reputation that cost you many weary days and self-sacrificing labor is at stake, and would you allow a charlatan to ruin it? By no means. For in all probability an unscrupulous medical man or empiric would be called in, and the waiting policy carried out. Should labor be tedious and threatening, and all safeguards to the mother broken down, your services would again be solicited, and the responsibility, shirked by the assuming doctor, finally thrust upon you, resulting either favorably or unfavorably, your professional reputation would be damaged irreparably in the community, and your vilification heralded by a thousand tongues from Dan to Beersheba.

CASE II. Mrs. B., aged thirty-three, multipara; fifth confinement; in her ninth month of pregnancy. I was called to see the patient April 7, 1887, at 2 A. M. The history, in brief, was that she had a few light labor pains the day before, and at intervals during the night slight hemorrhages No loss of blood during the preceding months. Shortly before my arrival the patient had bled so profusely as to saturate all the bedding under her. Her pulse rate was normal. On auscultation I could distinctly hear the fœtal heart sounds and uterine souffle. The patient stated, however, that she had not felt any movements for some time. Digital examination revealed the cervix dilated to the size of a dollar, and the placenta partly covering it.

Diagnosis.—Placenta prævia marginal.

Fearing a repetition of the experience I had with the former case, I sent for the late Dr. D. P. Moyer, in consultation. I plugged the os with bits of muslin saturated with vinegar, for hemostatic purposes, and filled the vagina in the same way. Upon the Doctor

making an examination another gush of blood followed. Stimulants were administered, and in our estimation the patient's condition would be endangered by delay, so rapid dilatation and delivery by the forceps was agreed upon. The use of an anæsthetic we agreed a perilous undertaking, as we suspected, from past knowledge of the patient, a phthisical tendency existed. Gently passing my right hand into the vagina I helped at dilatation with my fingers, permitting my hand to act as a tampon. Dilatation was easily and rapidly accomplished. Bleeding was now stopped, and being reassured of the viability of the fœtus we hastened delivery. Pressing my left hand upon the abdomen and supporting the uterus, I could determine with my right within the os that the vertex was presenting. The os being sufficiently dilated, I ruptured the membranes and soon the head became engaged at the superior strait. Not wishing to interfere with a natural process, we made no attempts at version. Leaving the patient in the dorsal position she had constantly occupied, I proceeded to apply the forceps. I had some difficulty in doing so, and the act was accompanied by more loss of blood. I had difficulty in locking the forceps, but why we could not determine, as the result showed they had been properly applied. Delivery was accomplished in less than three hours after taking charge of the case. The child was stillborn, and all efforts of Dr. Moyer at resuscitation were unsuccessful. The placenta followed in a few minutes. No attacks of syncope occurred in this case. The mother made a slow recovery. A rise of temperature occurred on the second day, and foul smelling lochia; but I ordered vaginal injections, thrice daily, of carbolized water, and prescribed several antipyretic doses of quinine, and in three days all abnormal symptoms disappeared.

The subsequent history, briefly narrated, may be of interest. On the seventh day an attack of phlegmasia-dolens came on, causing the right leg to become greatly swollen and painful from hip to toe. Quiet was enforced, limb elevated, and hot fomentations applied for ten days, when the pain and swelling had greatly lessened. Applied bandages, and later light friction, avoiding the larger veins, and stimulating lotions. The leg required three months to attain its former size. Medicinal treatment consisted of quinine and iron to sustain the system, and opium to relieve pain. Daily alvine dejections were secured by the used of sulphate of magnesia. One year after this she aborted, eight months pregnant; labor followed by adherent placenta. In nine months she again aborted a five months' pregnancy, and six months later died of consumption. Evidently a hereditary taint also existed, as both her parents died from consumption.

In cases like this, we should be largely guided by the viability or non viability of the fœtus. If no fœtal heart sounds can be heard upon a careful examination, nor has the mother felt any movements for some time, we should have no compunction about separating the placenta entirely, and inducing quick delivery. A thorough knowledge of the patient's previous history is of importance, as it was in this case; for suspecting the incipiency of phthisis, the exhibition of an anæsthetic would have been injudicious.

Case III.—Mrs. Y., aged twenty-two, multipara nine months pregnant; this being her second confinement; always enjoyed good health; the former labor difficult, and the child living only a day. No periodical hemorrhages during the preceding months.

I was hastily summoned on May 2, 1887, at 9 A.M., and found patient greatly alarmed at her condition. She had been doing light house work when a sudden gush of blood occurred, the patient, fainting, fell to the floor; the flow being so copious that her clothing, carpet, etc., were completely soaked in blood, with a pool about her. The patient was left lying in a comfortable condition until my arrival. Upon carrying her to bed in an adjoining room another flow occurred. Had I not seen the amount of blood lost I would have seriously doubted the condition of affairs if told me; not thinking it possible to lose so much blood without terminating fatally. By this time the patient was in an extreme exsanguine condition; countenance blanched, lips blue, breathing irregular, sighing and pulse hardly perceptible. Her very appearance appealed to me for instant aid for herself and unborn babe. Digital examination revealed the os more than half dilated. I could feel the margin of the placenta on the right side, to the extent of about three inches.

Diagnosis.—Placenta prævia marginal.

My examination dislodged the blood clots, and more blood was lost. At this instant an alarming syncope took place, and I now felt sure that death would end the scene in a few minutes. Stimulants had been regularly administered, and seemed to revive the patient. Forewarned is being forearmed. I carefully inserted my hand into the vagina, letting it act as a tampon in the os, and extending my index finger could feel the vertex presenting. The os being sufficiently expanded, I hoped for a speedy delivery. With the intention of accelerating labor, I ruptured the membranes, permitting the liquor amnii to escape, and slight bearing-down pains then became manifest, bringing the head to engage upon a margin of the placenta and checking the loss of blood. My hopes were realized. I made no attempts at version, as I could not see the necessity for doing so now in this case. The patient being completely exhausted, bearing down pains lessening, and her condition admitting of no delay, I administered a drachm of fld. ext. ergot, and proceeded to rapid delivery with the forceps. Leaving my patient in the dorsal position, I inserted my forceps without any difficulty. During this procedure the mother lost more blood, and was for a time pulseless; respiration had almost ceased, a desperate condition of affairs existed, and by main force I delivered, as expeditiously as possible into this world, a nine pound boy within two hours from the time I took charge of the case. Reaction came on in a few moments, the womb contracting, the placenta was expelled in a few minutes. No post-partum hemorrhages. The child was almost asphyxiated; but by continued efforts at resuscitation for a few minutes it began crying lustily. On the third day I found patient with a temperature of 103, and several rigors during the past night, and an offensive lochial discharge. I prescribed antipyretic doses of quinine, and ordered a vaginal injection of carbolized water thrice daily for three days, and had no further trouble with the case. The mother was left in a very anemic condition, but went on to a protracted, but complete recovery.

I solicit your criticism in these cases, knowing it will be just and varied; for unanimity of the plans of procedure and treatment of placenta prævia is the exception, and in this case the exception is the rule. No attempts at antiseptic midwifery were made; but absolute cleanliness was insisted upon. Delivery by the forceps is advocated as soon as sufficient dilatation exists to make it reasonably safe. Separate the placenta as far up as possible, especially that portion

adhering in the lower zone. Do not allow the placenta to escape before the birth of the child. The first consideration should be the mother's welfare. If assured of the viability of the fœtus, accelerate labor as much as possible, unless it would be seriously endangering the parent's life by haste, to give the child a reasonable chance of living; notwithstanding the teachings of some eminent authority to the contrary, which throws out all consideration for the child. In case of inertia of the uterus, or exhausted strength, administer ergot and stimulants, employ massage, or, better still, make pressure over the fundus, either by hand or with a binder. To control the hemorrhages the accoucheur's hand makes Your fingers will be equal to the gift of a third eye, an excellent dilator and tampon; however, a rubber dilator might be more desirable. In a case where the membranes were ruptured and the os only partly dilated, the greatest effort should be made to use the hand as a tampon and fingers as a dilator. As undesirable as this procedure may be to the attending physician, it is his bounden duty to use all possible means to save the patient's life. You have the means for rapid dilatation and delivery at command, and often this method is your patient's only salvation. and all changes will be instantly noted. Other means are dangerous. Escaping blood may be surreptitiously occupying the place vacated by the escaped waters, and suddenly the patient be lost. The physician had converted an open hemorrhage into a concealed one, and was unaware what was happening. Friends might attribute the sudden death of the patient to an act of Providence, but the observant attendant will now see his error; he had blinded his own eyes, deceived his own senses.

TRIPLE NARCOTIC ADDICTION.

OPIUM, ALCOHOL, COCAINE.

By J. B. MATTISON, M.D.

Member Amer. Assoc. for the Cure of Inebriety, of the New York Neurological Society, and of the Medical Society of the County of Kings.

HOME FOR HABITUÉS, BROOKLYN, N. Y.

Read before the American Association for the Cure of Inebriety, Hartford, November 6, 1890.

THE cases cited in this paper are of more than usual interest. Each tells its own story, and each has a moral that well adorns the tale.

Dr. A., married, aged thirty-four years, weight two hundred and three pounds, in 1879, while acting as interne in a New York hospital, took, for a severe attack of urticaria, a morphine hypodermic. It cured the rash, but consigned him to an opium bondage of nearly ten years, and, later, sixteen months' triple serfdom to morphine, alcohol and cocaine.

At the time of coming under our care, Dr. A. was daily taking, hypodermically, ten to thirty grains of morphine, ten to sixty grains cocaine, and twelve to sixteen ounces of rum. He weighed one hundred and fifty-five pounds, having lost forty-eight pounds. His heart and lungs were normal. The bowel torpor was marked—weekly dejections, and then only by enemas. He had occasional attacks of nausea, vomiting and anorexia. There was loss of memory, and mental hebetude. His skin was pallid and sallow, and sweating at night was profuse. The renal secretion was scanty; no other special feature noted. Sexual desire and power were almost nil.

Twenty-eight months before coming to us, he succeeded, with the aid of a devoted mother and the writer's plan of treatment, in breaking his bonds. One year of freedom followed. Then, under the stress of business cares, he gave way, and his last state became worse than the first. His weight fell from two hundred and three pounds to one hundred and forty-seven. Despite a morphine increase to thirty grains *per diem*, he had insomnic bouts lasting forty-eight hours, followed by great nervousness, inco-ordination, and extreme mental depression. Delusions of persecution with homicidal tendings followed the cocaine using.

Dr. B., married, aged forty-six, weight one hundred and forty-five, began morphine, hypodermically, in 1886, to relieve a long-standing neuralgia sequeling rectal fissure. His daily taking was usually ten grains, extremes four to sixty. One year ago he took a dose of cocaine, subcutaneously, for local anæsthesia, prior to lancing an abscess, and this opened the door to a new narcotic devil—reaching thirty-five grains a day. During the last six months he daily took six ounces of rum.

The results were:

Brain.—Hallucinations and delusions, homicidal and suicidal, after large doses of cocaine, or upon its sudden withdrawal, during the last six months. Moderate aphasia during the past year.

Heart.—Action constantly quickened, never under one hundred and twenty during the past two years.

Lungs.—Moderate general bronchial catarrh.

Stomach.—Catarrhal dyspepsia, with pain, especially at night.

Bowels.—Torpid before cocaine; free, after.

Skin.—Moist, sallow, and pale.

Sexual.—Entire loss of power and desire for two years.

Renal.—Daily amount, thirty-six ounces; albumen; no sugar; no casts; sp. gr., 1,036.

Soon after commencing cocaine, buccal mucous membrane became tender and painful, and, with the tongue, took on a peculiar reddish hue, which is thought to be characteristic of chronic cocaine poisoning—gums, tongue, and throat acquiring a condition said to be specific.

These gentlemen recovered. Dr. A. was under treatment six weeks; Dr. B. four. The writer's method—for details see *Therapeutic Gazette*, September, 1890, reprint at command—was used. There was nothing peculiar to their narcotic quitting and convalescence save that Dr. B. went through several storms of neuralgic pain, while Dr. A. had scarcely a twinge. Cannabis indica, Squibb's fluid extract, sixty minim doses, was the main hypnotic. Central galvanism, morning shower-baths, and full feeding were the roborants with Dr. A. Liberal diet with coca and quinine served Dr. B. The former's appetite assumed very ample dimensions, and his avoirdupois increased at a rate of ten pounds per fortnight. The latter put on forty-five pounds within three months after leaving.

Following our counsel, Dr. A. sailed for the Azores. Has lately returned, feeling well and weighing two hundred and four. He may abandon his profession. Dr. B., at this writing, is on the ocean, and will not resume work before '91.

What of the future? Much depends. If either begins practice too soon, he will succumb. The strain will be too great, and narcotics, either as stimulant or soporific, will be in demand, to be filled by one or all of the former drugs. Dr. B. must have months for getting well; Dr. A. *should* have *years*. The importance of hygienic care and favorable surroundings, after active medical need is ended in these cases, cannot be overestimated, and *they are absolutely essential to effect a lasting cure.*

"THE PROGNOSIS OF PRESSURE PARALYSIS."

By T. HALSTEAD MYERS M.D.,

Attending Orthopœdic Surgeon to St. Luke's Hospital; Assistant Surgeon to N. Y. Orthopœdic Dispensary.

AT the present time when surgeons are so eager to operate upon the spinal cord to relieve pressure paralysis, it is important if possible, to establish the prognosis of cases left without operation.

I have limited myself to a consideration of the pressure paralysis of Pott's disease, and the cases studied are all those which presented themselves at the New York Orthopœdic Dispensary up to the beginning of the present year, which have been kindly placed at my disposal by Dr. Shaffer. A number far too large to tabulate, hence my statements must be general ones.

Of these 1,570 cases, 218 were sooner or later paralyzed; 16 from disease of the cervical vertibræ, 12 cervico-dorsal, 105 from dorsal disease above the eighth, 40 from lower dorsal, 19 dorso lumbar, 18 lumbar, and 9 unspecified.

The average duration of the paraplegia of these cases in which it was noted, and which were known to have recovered, as estimated from the onset of any symptoms until the patient walked well, was in the cervical region twelve months, in the upper dorsal nine and one-half months, in the lower dorsal six, and in the lumbar eight months. The longest duration in the cervical region was twenty-four, in the upper dorsal forty-eight, in the lower dorsal twelve, and in the lumbar twenty-four months. I wish here to mention another case of cervico-dorsal disease, though its termination is not known, which was beginning to improve after a paralysis of five years' duration. The paralysis of the spincters having disappeared, and the child walking, though with ataxic gait.

It is interesting to note that of these 218 cases, 85 became paralyzed while under treatment (5 of these were in the cervical region, 53 in the upper dorsal, 21 in the lower dorsal, and 6 in the lumbar), and that in these the average duration, calculated in the same way, was less than that already noted, viz.: in the cervical region but five months as against twelve months; in the upper dorsal but seven as against nine and one-half; in the lower dorsal five against six, and in the lumbar but three as against eight months.

Eighteen of these 218 cases had repeated attacks of paralysis, usually the result of injury, acute disease, or lack of the proper attention to the braces. These subsequent attacks were of neither greater nor less duration, nor did they vary in severity as a rule from the original attacks, and they were recovered from equally well. Two cases had four attacks, and a number had three with good recovery. All cases, however, were not so fortunate, and I found two recorded where the patient had passed through one and two attacks, and finally died paraplegic.

The interval between the attacks varies from a few months to four and one-half years.

A late onset of paraplegia sometimes occurs. In one of these cases it first appeared seven and three-fourths years after the onset of the disease. The average duration of the disease, however, before the onset of paralysis, I found to be in the cervical region, also in the upper dorsal, thirteen months, in the lower dorsal fifteeen months, and in the lumbar eighteen months.

I found no cases where the bony lesion was below the motor area involved. Paralysis affecting the upper extremities was recorded in only 7 cases, of these 3 were not treated at all, 1 died after an operation on an abscess connected with the diseased spine, and 3 were cured.

Some cases recover without treatment; these records show 13 such.

That the character of the kyphosis does not affect the paraplegia is very well shown in 2 of these cases, where the improvement in the paralysis was coincident with well marked increase in the kyphosis.

The first indication of paraplegia is the exaggerated knee-jerk. This occurs sometimes a considerable time before the loss of motor power, and persists also after recovery from the latter. Weakness is the next symptom, the patient complains of getting tired easily. In most cases this is accompanied, as we should expect from the pathology, by pain or parasthesiæ, but it was surprising to me that many cases became bedridden without complaint of any accompanying pain. The motor paralysis usually attacks both lower extremities at once. In some cases, however, one limb is affected before the other, or more severely; in still rare cases but one extremity is attacked, or the paralysis affects the upper extremities as well. Ankle clonus is noted much less frequently than knee-jerk; usually this symptom disappears much earlier also. The superficial reflexes, unless well marked, are, I think, in children unreliable. Spastic rigidity of the limbs and anæsthesia are later symptoms indicating a very considerable degree of pressure. The muscular twitching movements, which are sometimes observed early, are due to irritation of an abnormally sensitive reflex arc, which may be theoretically either central or peripheral. This exaggeration of the reflex action makes it difficult to determine in some cases whether there is anæsthesia or not, as the muscular movement resulting from a pin prick seems closely to resemble a voluntary act. A child may besides be cognizant of the grosser movements of the limbs, though insensitive to painful impressions.

Paralysis of the bladder, almost exclusively in the form of incontinence, is noted in these cases much more frequently than rectal paralysis. I have seen the statement that cases in which the bladder was paralyzed for three months would probably never recover. In my cases which recovered, several were paralyzed for two months, and 2 between three and four months.

The first evidence of improvement is cessation of pain (where it exists), then diminution of the clonus, with a gradual return of power to the affected limbs. The exaggeration of the knee-jerk often persists months after the patient is able to walk well. In one case it was present nine months after. In cases of repeated attacks of motor paralysis it sometimes almost bridges the interval between the attacks, though this is by no means universally so, and I hesitate to say more than that it is taking a risk to let a case with exaggerated knee-jerk walk. On the other hand, I think a patient with ankle clonus should never walk.

The presence or absence of abscess seems to make no difference in the prognosis of the paralysis. A sudden onset, or a sudden relief from pressure symptoms, not associated with traumatism, I think, is due in some cases to rupture of an abscess into or from the spinal canal; I have seen two beautiful specimens of the former accident.

The prognosis of paralysis depends upon the extent of the cord lesion, which we have found is independent of the extent or character of the kyphosis, the rapidity of the onset or the duration of the disease, but is dependent somewhat on the location. I know

of no perfectly certain indication of the extent of cord lesion. It is most accurately determined by the atrophic condition of the muscles, whose nutrition is controlled by the affected region of the cord, by the electrical reactions of these muscles and their nerves, and by the condition of the reflex arc at this point. The duration of the sensory symptoms, as of the motor symptoms, even the paralysis of the rectum or bladder, are simply confirmatory.

The prognosis is in general very good. Of the 218 cases, though 55 per cent. only are *known* to have recovered, 26 per cent. (none included in the recoveries) were not treated at all, and at once passed from observation, 3½ per cent. died of intercurrent disease, and the termination of the remaining 16 per cent. is unknown.

THE WEST INDIES AS A SANITARIUM.

By WILLIAM F. HUTCHINSON, M.D.

CHAPTER VI.

SANDWICHED between two islands of the British West Indies, lie three or four that belong to France. Indeed, a great portion of the charm that a voyage down here possesses, is due to the fact that within a very short space of time and distance, one may change not only the nationality of the country he is in, but the customs, manners and surroundings as well.

To go from Spain to Denmark, from Denmark to England, from England to France, and back again to British territory, to do all this within a hundred miles of travel, and to find in each outlying island the country to which it belongs far more strongly national and characteristic in its customs than the fatherland itself, is what one can only do in the West Indies.

Emigrants who come here from Europe rarely return. They preserve and transmit to their descendants the ways and means of the homeland as a part of their patrimony, and since they themselves may never see it more, they build around them as close an imitation as circumstances permit. By years of practice these circumstances become more and more accented, and things that are most strongly marked in the fatherland become more and more developed and pronounced, till the Cuban becomes twice a Spaniard, a Barbadian three times an Englishman, and a Martiniquien four times a Frenchman. So that we have in each of these islands that we successively visit, an epitome of the country to which it belongs presented to us in a concentrated way that is perhaps more completely illustrative of the lands to which they belonged than would be years of residence in Europe.

So within six hours after leaving England behind at Domenica, we step ashore in France at Guadeloupe, and in France of the last century.

Nothing is more peculiarly Gallic than the first view of a street in Point-a-Pitre. There are these exceptions it is true; that the people we meet are black instead of white, that the sun that shines upon us is perpetual instead of intermittent, and that the temperature is many degrees higher than in even the sunny parts of France; but the tongue we hear, the language that is spoken is pure, and barring a certain accent that seems as if it may have been borrowed from the hot land where we hear it, one might close his eyes and be at Marseilles.

Beneath the rays of a tropical sun that beat down upon our unaccustomed heads with fury, these Frenchmen wear black clothes and silk hats, and stroll about the streets under the shade of sun umbrellas when the thermometer marks ninety at coolest time of day.

Our tourists paid small attention to such trifles as sun or heat, pervading the streets of this Franco Indian town with so much celerity and perseverance as to give the idea that their numbers were scores in place of four. They captured carriages of our guides, carrying each in hand a French phrase book from which they manufactured sentences so extraordinary in sound and accent that the amused natives took their money, guessed at what they wanted, handed out a mixture of cool drinks and all parties were content.

That novel experience to Americans, of wine served free at dinner in any desired quantity, first made its appearance to us at Point-a Pitre, and our young gentlemen, winking at each other as they sat down at the table at the pleasant "Hotel des Bains," drew each to himself a quart bottle of claret, filled a brimming glass and proceeded to dine as pleased as possible. Before the meal was finished they had taken care of more wine than they had of food, and the result of general extreme hilarity suited so well the temperament of the natives that a profound friendship was struck up and cemented by more flowing bowls and noisy shouting of the "Marsellaise" and "Star Spangled Banner" in frightful combination.

One of the most attractive places to visit in Guadeloupe, guided by a Freemason, is the Masonic Temple at Point-a Pitre. Upon a hill within the town a building of Egyptian style has been erected, the grounds around which comprise the entire elevation. At the foot a wall separates the consecrated land from outside territory, and the whole of the enclosure is devoted to Masonic purposes, where there is a home furnished for the wandering brother who finds himself drifting in this far-off land. Since heretics may not be buried in Catholic countries in consecrated soil, these brothers of the order that know no religion except that independent of any sect, have laid out within their grounds a pretty cemetery where any one who dies within their jurisdiction, belonging to the order, may be buried in ground that is holier than any consecrated by the church.

Thus in these islands of the Indies, Freemasonry finds its truest and widest exponent, and brotherhood here is not merely a word, but has the signification which should belong to it everywhere.

It is difficult in so short a stay as I made in Guadeloupe to ascertain much about its sanitary condition, or diseases of the island, but as it is unlikely that American tourists will do more than pay a flying visit here, a few words are all that may be necessary.

Within the last few years both Guadeloupe and Martinique have been ravaged by small-pox. Following the example of the mother country where compulsory vaccination has never been the rule, they have not attempted to enforce it, and the result was a frightful epidemic. This has now disappeared, I believe more from lack of material than any other cause, and the islands are in a state of health.

I noticed particularly open sewers continually flushed by rapid streams of pure mountain water that carry all impurities promptly to the sea, and even in the most crowded parts of the town there are no unpleasant odors whatever.

Such a thing as a water-closet, as we understand the word, does not exist in these two islands, with the sole exception of one or two in a club house or private dwelling, and the primitive method of using tubs which are emptied every morning at daylight into these swift streams by the street-side, is still in vogue.

Food of all kinds is plentiful and cheap, and one may board at the first hotels here and in Martinique, with comfortable rooms and all service, for two dollars a day.

Drives out of town are numerous and attractive, and a party may hire a two-horse carriage for about four dollars a day, which will carry three persons beside the driver. They will find their coachman communicative and intelligent, ready to tell them of the places that they pass, and keep them amused from start to finish; only some one, or all of the party must speak French, for a knowledge of the English language is so great a rarity that I only found in my wanderings about town a single person who could speak our tongue, and that was a servant at the hotel.

The artist will find in all the towns of this island plenty of quaint objects of a past age, plenty of bits of exquisite scenery to occupy his pencil for many a day, and some of the photographs that I brought thence have been admired, not only for their artistic beauty, but for the wealth of suggestion that they contain.

I would advise any one who can find time to spare, to spend a couple of weeks in this curious, quaint, and attractive island. He will find in the American Consul at Point-a-Pitre an intelligent, courteous gentleman, whose long residence there has made him almost a Frenchman, while he has not forgotten his love for his native New England, nor to show warm hospitality to his wandering countrymen.

From Guadeloupe to Martinique is but a beautiful twelve hours' sail. When the first stars of a tropic night are gleaming from the sky that is so dark a blue as to be almost black, the steamer gets its anchor and heads away to the southward for the island of Josephine. While yet these same stars shine, mingling their light with the morning sun, the ship skirts along under a rocky and bold coast, whose contours of soft roundness are sharply alternated with peaks, rocks, dark gorges, and streams that leap hundreds of feet directly to the sea.

The bay of St. Pierre is one of the most picturesque in these beautiful islands; but it must be understood that this is only one of several that Martinique possesses, and that although the city we now approach is the leading one of commerce, and the largest in population, it is not the capital, nor has it that harbor that has made Martinique an object of envy to every power that owns territory down here. Yet the picture is a beautiful one; and whoever sees the morning sun rise over mountain peaks behind the town for the first time, scattering shadows that have concealed cathedral towers, red tiled roofs, and tall palms like curving plumes, on its way westward, touching the shining water with polished lances of light, will not be likely to forget the harbor of St. Pierre.

Like Guadeloupe, the landing is essentially French. Boats of every description surround the ship, and every boatman shouts his loudest in his native tongue, "Prenez moi, Monsieur, je suis le premier."

The most extraordinary apparatus in the shape of boat that mortal eye ever beheld, dances around the anchored ship at St. Pierre. It resembles nothing so much in all this world as a coffin made of rough boards, with the top left off. The occupant, however, so far from being dead, is the liveliest little darkey that it is possible to conceive. He paddles his funny boat from shore with his hands, and sits upon its bottom as destitute of clothes as when he was born, ready to dive like a frog for the smallest coin that may be thrown him from the deck above. He always gets it, too.

From the landing-place to the Hotel des Bains is but a short walk, scarcely impeded by a visit to the custom-house, whose officers are so polite to tourists that they never open any trunks at all, and mark them "All right," with a courteous wish that our stay in the island may be pleasant.

The first view of a French West Indian hotel is a revelation of oddity to a stranger. Outside it presents no especial difference from other houses in the block. Inside one finds a paved court and an immense cage, where fowls of various kinds are waiting their call to serve as parts of the dinner each day. Why this cage exists none can tell, for its doors are always open, and the fowls amuse themselves by excursions into the various sleeping-chambers, to which they have free access day and night.

All the rooms open inward on galleries, and if at any time one needs a servant, he steps out and calls for Marie or Justine, as the case may be. If she is away upon an errand, some one answers for her, "Tout de suite, Monsieur," which means anywhere from half an hour to half a day. If she is there she replies, "On viens, Monsieur," and is forthwith at your door.

The very moderate charge of $2 per diem means bed and three good meals a day—wine and service included—and I am bound to say that all were content. The first breakfast is brought to the room at 6 o'clock, and one eats enough of rolls, Danish butter, soft boiled eggs, and delicious coffee with milk, to last till the regular breakfast comes at noon. This is an elaborate meal of six or seven courses, with plenty of good claret, differing only from dinner—that comes at 7—in the latter having soup to begin with, and a few more courses. After dinner a cigar and chat for the gentlemen, and then comes bed; and by 9 o'clock the town is asleep.

It is true that minor annoyances of insects are by no means absent. Cockroaches the size of mice, that travel over the bare floor in the dark; centipedes six inches long, that are now and then killed under one's dining table, are at first annoying, but one soon learns to make light of them, as they never do any real harm. Spiders are of prodigious dimensions in all these tropical islands. My friend Garesche, the gentlemanly American Consul, showed one in his drawing-room that had remained patiently in one position upon the ceiling for several weeks. "When he gets hungry," said the Consul, "he comes down, hunts up one or two cockroaches, and is content for an indefinite time thereafter to remain quiet at his post."

After the first breakfast was over, we found amusement plenty in wandering about the quaint, curious streets, looking in the little shops that were filled with things strange to Northern eyes, and inflicting upon the polite owners a series of questions in what we were pleased to call French; or, calling a carriage—and, as in Guadeloupe, one may have a double team here all day for $4 that will carry three beside the driver—start for a journey amongst some of the most attractive scenery that the world knows.

Without being hot at any time, the air is simply delicious in the morning. It comes pure and sweet from the lofty mountains around the town, mingling with the fresh water of the clouds, and the salt sea-breeze from the sea, at a temperature which, during our entire stay, did not exceed 80° at the highest, and sharply fell from that point as we climbed the mountain roads, until within an hour's drive from the hotel to Mont Rouge, we found light overcoats comfortable, and my pocket thermometer 66° at noonday.

One of these delightful drives carried us to one of the famous medicinal baths of the world. It is called Les Fontaines Chaudes, and lies in a deep gorge that cleaves the island's surface from mountain peak to sea, some twelve miles distant from town.

The only difficulty that I found with these thermal springs as a resort was, that from the last point attainable to the Springs Hotel it was necessary to walk or be carried over a rough road of about a quarter of a mile. At the springs is comfortable accommodation for a numerous party. The water is strongly sulphurous, at a temperature of 105° where it enters these swimming baths, and 95° where it leaves them. The basins are large and well cared for, special accommodations being provided for men and women. A medical man has charge of them, and of the hotel as well, and he assured me that some really wonderful cures of rheumatism and allied affections were effected. He gave me an analysis of the water, which showed its percentage of sulphur in gaseous form to be as large as any on record. It contains besides, silica, lime, and soda to an appreciable extent, and one feels after leaving the bath, where no soap is used, as if he had been oiled from head to foot.

Another delightful excursion is the one to Fort de France, the ancient capital of the island, and still the residence of the Governor. Here is a magnificent harbor, almost land-locked, with immense capacity inside, and surrounded by lofty peaks that shut off all danger even from hurricanes. In the middle of the great square that is the chief attraction of the place stands a beautiful marble statue of the Empress Josephine, erected to her memory by Napoleon III. She was born at the little hamlet of Trois Islets, farther on across the bay, and the place is more alive with memories of this woman than is even our own Mount Vernon of Washington.

Around Fort de France there are also numerous thermal springs, access to which is easy, but they do not possess either swimming baths or a hotel close by.

I found these two islands singularly destitute of lepers in the streets. Making inquiry of one of the leading physicians, I was told that the disease scarcely exists — at least in comparison with the English islands—and that as soon as a case appeared it was promptly isolated; nor was there, at the time of our visit, any epidemic disease whatever.

At the time of year that includes winter months there is no such thing as yellow fever, and moderate precautions as to diet and exposure to the heated midday sun are sufficient to insure to visiting strangers continued health.

At home, one hears on every hand stories of poisonous serpents of Martinique, that are called the iron lance (le lance de fer). That there are numbers of these snakes in the island is doubtless true, for the records show some twenty-five deaths per annum among native negroes from their bite; yet, in several visits to Martinique, and continual wandering over its beautiful roads, I have never made the personal acquaintance of a single living specimen. During one of my visits I offered a reward for one of then, alive or dead, but none were forthcoming, and the only one I ever saw was a specimen mounted for exhibition at the botanical garden. There is no more danger from serpents in Martinique than there is in the Adirondack region.

Nights are invariably cool and refreshing, and the trade wind blows so strongly through sleeping rooms that a blanket covering was very comfortable during our entire stay.

In place of the light clothing one expects to see, gentlemen of these islands wear conventional black, and appear comfortable therein, while the ladies rarely use for street wear anything thinner than one sees on Broadway or Chestnut street in May.

MARTINIQUE, MARCH, 1890.

The Polyclinic.

POTASSIUM iodide has been given by Wolf in doses of from 30 to 50 gm. daily in obstinate cases of tertiary syphillis. It is dissolved in a decoction of rice in order to prevent iodism. The same salt was also given in large doses in a case of psoriasis by Dr. Stenhouse, who administered to a young lady 100 ounces of potassium iodide from March 8 to August 3, the largest doses being 210 grains three times a day. Its influence over the psoriasis did not appear until 360 grains were taken daily.

—*Journal of Pharmacy.*

POMADE FOR PRURIGO.

℞.—Boric acid,
White wax.....āā 10 parts.
Parafine ..... 20 "
Olive oil ..... 60 "

—Kaposi, *Journal of Pharmacy.*

When having introduced a probe into a lachrymal duct do not let it rest on the floor of the nares, but withdraw it slightly, otherwise it may occasion a painful toothache.

Occlusion of the lachrymal duct, Keyser believes is due to an ascending catarrh from the nasal passages. Some maintain that it is due to an extension of inflammation of the conjunctiva through the puncta lachrymalia, but Keyser thinks that impossible, for the first evidence of inflammation at the puncta would so occlude it by swelling that further extension of the inflammation would not be possible.

W. C. Drake, in the *Druggists' Circular*, submits a number of well tried receipts for toilet preparations, from which we select the following:

Lime juice and glycerine for the hair.

Benne oil ..... 16 ozs.
Lime water..... 24 "

Put the oil in a large mortar, and gradually add the lime water, using an egg beater, thoroughly mixing them. Perfume with a half ounce of a mixture of

Oil of bergamot ..... 8 drachms.
Oil of lemon.. ..... 4 "
Oil of lavender..... 2 "
Oil of cloves..... 1 drachm.

This preparation is put up in 4 ounce bottles, and closed with corks which have been soaked a short time in an alcoholic solution of corrosive sublimate, 1 grain to the ounce to prevent mold.

A good disinfectant injection for leucorrhœa is:

℞.—Potassii chlorat..... ℥iij.
Tinc. opii ..... f℥ijss.
Aquæ picis..... f℥ix.

Fiat. sol. Two or three soupspoonfuls of this solution in a quart of hot water may be used as an injection, morning and evening, to correct the fœtidity of leucorrhœic discharges which accompany some cases of endometritis, polypus, fibrous bodies, ulceration of the cervix uteri, or even simple vaginitis. The injection should last five to six minutes each time.

TREATMENT OF SYPHILIS BY SUBCUTANEOUS INJECTIONS OF CALOMEL.

IN the year 1864, when Scarenzio published the results of his treatment of eight cases of syphilis by hypodermic injections of calomel, little interest was taken in the matter. This was due partly to the prevailing preference to the treatment by inunction, and also to the fact that Lewin had been pushing into prominence the treatment of syphilis by subcutaneous injections of corrosive sublimate.

Scarenzio injected the drug suspended in glycerine, but later abandoned this medium for a solution of gum arabic. According to his views three or four injections of 0.1 gramme of calomel were all that were required, and he also stated that two or three injections of calomel would accomplish more than twenty or thirty injections of corrosive sublimate. Abscesses resulted nearly always. In 1872, Schopf, a German syphilographer, used calomel injections with similar results, but complained against the almost invariable formation of abscesses; he also noted a frequent occurrence of stomatitis. Kölliker, on the contrary, claimed that calomel injections were less liable to produce abscesses than sublimate injections. And so on, numbers of physicians tested the method, all with success regarding its efficacy, but with varied experiences regarding the accompanying and after symptoms.

The best, among the earlier results, were those obtained by Watrascewski, in 1884. He used calomel in suspension in a solution of gum arabic; and injections containing 0.1 gramme of calomel into the gluteal region once in one or two weeks. Seventy patients were submitted to the treatment, and in all two hundred and fifty-seven injections were made. The formation of abscesses was only observed in four instances. Usually three injections were sufficient to effect a cure. The injections were but slightly painful.

Shortly after these experiments Neisser suggested the use of the following formula for injection:

R.—Calomel,
Natr. chlor., ... āā 5.0 grammes.
Aq. destill., ... 50.0 grammes.
Mucil gumm., ... 2.5 " —M.

He gave four to six injections—either one a week, or all within two weeks. While commenting favorably upon the method, he gave it the second place in the treatment of syphilis, holding inunction to be more valuable. He gave, in all, 717 injections, and observed the formation of abscesses in 31 cases; most of which were due, however, to bad technique. At the Fifth Congress for Internal Medicine, at Wiesbaden, Neisser again made reference to the treatment, and was supported by Doutrelepont, although the latter claimed the superiority of the treatment by inunction. Edlessan, at the same Congress, went still further, and stated that relapses were more frequent after the treatment by injection than after inunction. Of late, since the technology of hypodermic injections—and especially antisepsis—has been more generally understood and followed, the method has been steadily gaining favor, and is now ranked as the most practical, if not the most efficacious method of dealing with syphilis.

Regarding the theory that relapses are more likely to occur after the use of calomel by injections, this still remains to be proved. The formation of abscesses can be entirely avoided, and is only the result of carelessness—not necessarily on the part of the physician, but possibly on the part of the druggist; for, if the preparation has been rendered impure, or carelessly compounded, even the most stringent antisepsis will be unavailing. It should be compounded in glasses cleaned with hot water, and disinfected immediately before their use. The syringe must be aseptic. It should be taken apart, and allowed to soak in a five per cent. solution of carbolic acid for at least half an hour. It is a good precaution to use a new canula for every patient, or at least have the point re-ground. Then, the seat chosen for the injection should be rendered aseptic by means of scouring with brush, soap, and hot water, and washing with ether and a five per cent. solution of carbolic acid. The syringe should be filled with the injection fluid in such a manner that below and above the calomel solution there is a drop of the five per cent. carbolic acid solution. The calomel must be prepared with infinite care, and suspended in the purest olive oil. Immediately after the injection, the puncture should be dusted with iodoform and protected with a carbolized dressing, which must be kept in place for twenty-four hours at least. It is well, also, to keep the patient quiet for the first twenty-four hours after the injection; but this is not absolutely essential.

The method, as described above, is that which has recently been used with marked success by Dr. A. Vogeler, whose paper on the subject, in the *Berliner Klinische Wochenschrift*, may be classed as one of the most complete ever written upon this subject.

That the method is entirely free from danger cannot be said, as cases of profound mercurial poisoning have been observed; but these are extremely rare, and, as a rule, even diarrhœa is not occasioned. In such cases, the puncture should be at once opened and the poison removed, while other remedies should actively be employed, such as large injections of hot water into the bowels, etc. The wound, also, should be freely opened, cauterized, and well washed out.

In conclusion, the advantages of the method over inunction, and other methods, may be summed up as follows :

1. It is clean.
2. It is cheap.
3. It is convenient—both for patient and physician.
4. It is reliable in all forms of syphilis.
5. The amount of the drug introduced into the system can be accurately determined.
6. Pain or infiltration are rare when the injections are given in the ischio-rectal region.
7. Abscesses can be entirely avoided.
8. The method may be regarded as safe. Even in cases of intoxication—which are very rare—a removal of the poison by opening up the seat of the puncture and washing the wound, will cause a speedy abatement of all unpleasant symptoms.
9. Stomatitis is only observed in a mild degree, and may be greatly lessened, if proper care is taken of the mouth.

Annotations.

PLEASURE AND PAIN.

THE *Popular Science Monthly* for December, contains, amongst other articles of general scientific interest, one by Dr. E. Heinrich Kisch, on The Sensation of Pleasure and Pain, which contains some interesting hints on the causes of neuralgia, and general nervous affections. Speaking of feeling pain, the doctor says "That a stimulus striking the sensitive nerves should reach our consciousness as a pain depends not on the force of the attack only, but also on the delicacy of the nervous system, which varies with different men to a considerable degree." And it is this to which, too often, we ascribe nervousness or coolness. The nervous systems of some men are so delicate that the slightest sound or the least shock jars them; the shock paralyzes the brain, and the whole body is unstrung. And to the man of a less delicate nerve organization the shock reaches the brain far more slowly, the brain is left undisturbed and acts, and the shock is, perhaps, really felt when the occasion which has given rise to it has passed.

HUNGER AND SUSCEPTIBILITY TO INFECTION.

IT is a pretty well-known fact that when hungry or tired, one is more apt to take scarlet fever and other infectious diseases than after an easy day and a good dinner. Experimental observations have recently been made by some Italian observers, which are spoken of in the *Hospital Gazette*, and which tend to show that hunger may play a very important *rôle* indeed in the spread of infectious diseases. Pigeons and fowls are not usually susceptible to the infection of malignant pustule or charbon. When, however, pigeons were kept without sufficient food for several days, both before and after inoculation with charbon virus, they became susceptible to the disease, and died from it like other animals; and when they were kept without sufficient food for some days before inoculation, and for two days only afterwards, food being then supplied in proper quantity, the disease, though not prevented, was visibly affected, its course being much more chronic than when the birds were kept hungry for a week or more after inoculation. Another interesting point observed was, that if an ordinary well-nourished and, therefore, insusceptible pigeon was inoculated, and complete starvation commenced eight days later, the disease appeared showing that the charbon virus, though stored in the subcutaneous tissues of an insusceptible animal, retains its virulence for several days. Some experiments were likewise made on pigeons, from which the pancreas had been partially or entirely removed. These appeared to become susceptible to the charbon virus for some time after the operation.

COINAGE AND INFECTION.

IT is no new doctrine says the *Lancet* that in the presence of infectious or contagious disease every object may become endowed with a mischievous faculty of transmission. Nothing is exempt, though some substances are naturally better fitted to act as media than others. Such substances as clothing and carpets may be placed in the first rank, and paper, especially in the book form, hardly second. The scrupulous rigor with which measures of purification are adopted in regard to all these is proof of the wholesome suspicion with which they are commonly invested. It was not to be expected that paper money could escape the stigma, nor should it. Even solid coin has latterly been credited with the same maleficent property. It cannot be denied, indeed, that any penny or shilling may thus be made to bear a novel and mischievous increment of its own. At the same time we can avail ourselves of the relief afforded by modifying circumstances. It is well, for example, to remember the wholesome qualifications introduced by the moving and ventilating process of currency, by the protection of a purse, and by a generally smooth and well-polished metallic surface. On a critical examination of the subject, we are tempted, notwithstanding, to look back with some regret to the old custom of washing change. To insist upon this in ordinary cases of infection would, indeed, be fanciful and unpractical, though we might forgive such pious care. Where, on the other hand, we had to deal with foul and active contagion, we should not care to ridicule one who disinfected his change. In so doing, he only obeys the suggestion of cleanliness and caution.

MISSION WORK OF THE PHILADELPHIA BOARD OF HEALTH.

RECENT circulars published by the Pennsylvania State Board of Health contain much that is sound, and show that sanitation is being carried on, or, at any rate, discussed on the most practical lines. Of special interest is the one "addressed to the clergy," and examining briefly "the dangers arising from public funerals of those who have died from contagious and infectious diseases." As there is so much outcry in these days against cremation, the clergy should at least be careful to guard ignorant, and often misguided people, against any danger of infection by striving to prevent any one being in attendance at the services and interment, even, if possible, to the extent of keeping the immediate family away. In this report cases are sited of whole districts being infected by the attendance of numbers of people at the funerals of those who had died of infectious diseases. But, although this report is specially addressed to the clergy, and merits special attention from them, yet they are by no means the only people upon whom rests the grave responsibility

of the cure of this evil. Much which the clergyman fails to do the physician has the power to accomplish, and every doctor in the land should recognize his duty to prevent the spread of disease. Men in the position, in relation to the laity, which both clergymen and doctors occupy, can do much to put an end to such evils.

The other report of the Board deals with the disposal of the sewage of public edifices, and "rings with no uncertain sound" on the criminality of the pollution of streams by sewage. Among other things which it contains is an extract from a very able opinion of Judge Thayer, of Philadelphia, in which he says, "It is a very old and well settled law that to pollute a public stream is to maintain a common nuisance. It is not only a public injury, but it is a crime, a crime for which those who perpetrate it are answerable in a tribunal of criminal jurisprudence." It certainly seems as if municipal authorities were altogether too lax, or, shall we say, too ignorant, on this matter of drainage, and every intelligent citizen would do well to inform himself on the subject, and do all in his power to counteract the stupidity of city contractors.

REPRODUCTION OF BACTERIA.

IT has been very reliably determined that bacteria, when placed in the best conditions for their activity, will double their number every hour. In most favorable circumstances it will then be seen that a single bacterium will, in twenty-four hours, produce 16,777,220 of its kind. According to the *Sanitary News*, in forty-eight hours, from this single source, the number of bacteria would amount to 281,500,000,000, a quantity sufficient to fill a pint measure, all produced in this short time from a single micro-organism measuring but 1-15000 of an inch. Fortunately, these conditions do not often exist. The reproduction of bacteria is opposed by many kinds of forces and they have a continual battle for existence. In regard to the disease producing or pathogenic germs, it is important to understand what forces or agencies will retard their multiplication or wholly destroy them. In emergencies chemistry is resorted to and antiseptics employed, but in the proper prevention of disease such emergencies should not be allowed to arise. Sunlight, pure air and thorough cleanliness are natural enemies to disease germs. They cannot flourish where they have not their proper food, and that is found in dampness, darkness, mold and filth. Keep the habitation flooded with sunshine and pure air, keep away all filth and dampness, and the germs of disease will find no foothold, no nidus in which to breed, or food on which to grow. Nature is struggling all the time to keep her domain healthful, and a fit habitation for man, but man shuts out the air and light, contaminates all things about him, and disease is the reward of his recklessness and neglect. There is more health in a sunbeam than in drugs, and more life in pure air than in the physician's skill. The sunlight may fade your parlor carpet, but better that than have disease fade your cheek. The wind may "tan" and "freckle" the face, but it is better tanned and freckled than thin and sallow. Help nature to keep your habitation healthful by allowing her forces an opportunity to operate. There is more health about you than disease. Health is man's natural condition. He has to violate some law before the penalty of disease is inflicted. He can place about him such conditions that disease germs will evade his system, or he can live amid surroundings so pure that health will bless him both in his freedom from physical ills and in the sweet consciousness of right living.

THE AMERICAN PHYSIQUE.

PROF. N. S. SHALER, writing in the *Literary Digest* on Nature and Man in America, makes the following interesting statement concerning the physical development of American men, to which we invite the special attention of all interested in physical training, as well as to those Anglo-maniacs who are forever forcing home upon us the superiority of the English and Germans:

There has been a good deal of talk about the American type of man. He is supposed to be a thinner and more angular creature than his cousins of the parent isle, and it has been held that though quicker witted and readier to fit himself to circumstances, he has less solidity and less endurance than his ancestors from beyond the seas; but although it must be admitted that our climate, as a whole, differs considerably from the conditions of northern Europe, whence our race came, and, consequently, that a certain measure of physical change in that race might have taken place in this country, yet there is ground for believing that the change, if it has occurred, is small, and is not an alteration for the worse. From a comparison of the registers of measurements made for army purposes, it appears that American soldiers are, on the whole, as well developed as those who fill the ranks of European armies. The records of insurance companies show, that the American man lives longer than men of the same race in the Old World. The ready recovery from wounds and the success of grave surgical operations during our Civil War, under circumstances which were, on the whole, less advantageous than those which attend the conduct of war in Europe, prove that the American body has more recuperative power than that of the European. The interest the American takes and the success he achieves in foot-ball and other out-door amusements, is an indication of his mental activity and physical vigor. And, lastly, the conduct of our army and people as a whole, during, as well as since the war, justifies us in claiming, that the race has certainly not lost the moral qualities that marked it in the Old World. This convergence of testimony may be safely taken to justify the assertion that the climatic and other conditions of our continent, excepting the Arctic region and the district about the Gulf of Mexico, are favorable to the development of Northern Europeans. We may, therefore, dismiss the fear that our race is to deteriorate in this country, but we must also put aside the notion that we are to be a massive and unvaried people. The present structure of our social and economic life permits rapid changes in the occupations of men, and thus makes the effect of occupation on *physique* imperceptible; but with the increase and consolidation of our population, vocations will become more hereditary, man will be employed at the plough, in the mine and in the mill from generation to generation; and then each community will bear the distinctive stamp which comes only through ancestral habit.

Letters to the Editor.

I FIND, in a recent report of the transactions of the Philadelphia Obstetrical Society (Annals of Gynecology and Pediatry for November, 1890), the following statement, made by Dr. J. Price: "The question has been asked when to use electricity. There is a simple answer to all that—never. How, when, and by whom? At no time; never, and by no one. It has no place in medicine."

These remarks, and the sentiment of intolerance which they represent, seem to me so extraordinary in a scientific discussion of the present day, that I must believe that they were made in a moment of irritation, which overbalanced Dr. Price's judgment for the moment, since they are both utterly untrue and bitterly ungenerous. That electricity has a distinct place in therapeutics—as hardly won as that of quinine, and as palpable of demonstration—hundreds of doctors and thousands of patients are ready to testify.

In certain forms of paralysis, in many atonic conditions, and in all forms of hysteria, its value is incontestible, except in heated discussion; and neuralgias dependent upon local causes will disappear more quickly and permanently under galvanic currents, properly administered, than in any other way.

Indeed, to some of us who are accustomed to daily use of electricity in medicine, Dr. Price's statements are simply absurd. We see so many patients cured by its use, of derangements that have been pronounced incurable by general practitioners, that our confidence, and, I am happy to say, the confidence of the profession at large, is steadily growing in its value as a curative agent.

Perhaps, however, Dr. Price has had too much experience with electricity in surgery—where its status is not yet fully defined—and none in medicine—where it is now used as confidently as quinine or opium; and this may explain his unfair words. Or, he may be personally unacquainted with what has been done with electricity therapeutically; or—or there may be many reasons why he should have used them.

At all events, they were calculated to do harm if uncontradicted, and I am glad to bear testimony against them. In my belief, electricity has a definite, established position in medicine; one which is steadily improving, and cannot be shaken by such remarks as those in question. WM. F. HUTCHINSON.

PROVIDENCE, R. I.

Book Notices.

MEMORIAL SKETCHES OF DOCTOR MOSES GUNN, BY HIS WIFE. With extracts from his Letters and Eulogistic Tributes. Chicago; W. T. Keener, 1889.

This book is about an interesting man; but the picture which we get is too fragmentary and detached, and the loving wife who has compiled the sketches is not, it seems to us, sufficiently in the background. Dr. Gunn was born in 1822, and his life, which extended over sixty-five years, was one long devotion to the profession which he had chosen and which he loved. Of special interest are his letters written from camp during the war, letters which give an excellent picture of the life of a camp-surgeon in Virginia. These letters, written during the hurry and interval of a busy army life, have a great freshness and charm. Dr. Gunn's two great personal characteristics were a love of horses and the power of telling a good story. The accounts of his various horses and of his love for them are highly entertaining.

Professionally, while Dr. Gunn occupied a high position as a surgeon, no great discoveries, no great experiments in original research have made his name famous. But great surgical ability, profound enthusiasm for his profession, and winning social qualities made his a household name wherever his personal contact was felt. On the whole, the impression left on our minds in reading this book, is to join in Sam Weller's "vish there vas more," although we should prefer it all in a more biographical form.

THE PRACTICAL APPLICATION OF ELECTRICITY IN MEDICINE AND SURGERY. By R. W. ST. CLAIR, A.M., M.D. 8vo., pp. vi—222—viii. Philadelphia: R. H. Andrews, M.D. (editor of the *Med. Summary*), 1890.

The author issues this book as a purely practical work—a guide for those who have neither the time nor the inclination to wade through the cumbrous mass of extraneous material found in so many so-called "text-books," works which are unintelligible to those who are not up in the integral calculus, and *au fait* in algebra all through. He has done this thoroughly; the plan is plain, the diction clear, the facts correct. The range of subjects taken up as amenable to electric treatment is long, and in some instances those who are unfamiliar with what the current scientifically applied can do, will be somewhat incredulous; they need but try, and see for themselves. He does not confine himself to one kind of battery, but gives a fair estimate of the value of many different makes; it is evident, however, that the "dry cell chloride of silver" element (Barrett's of Baltimore, Md.), is the favorite, as it should certainly be. The advantages of static electricity in its place are well shown, and it is to be hoped that his readers may be influenced by what he says in this direction, for much foolish twaddle has been spent in decrying this form of energy, not only by those who talk for talk's sake in medical societies, but by others who in popular and scientific journals make statements at once misleading to inquirers, and radically untrue in themselves. The book is a good one; and it will repay its owner even if he is up in the science of electricity. All points needing illustration are taken care of by fine electrotypes—the paper and binding are first-class, and the whole appearance is creditable alike to the author and the gentleman how issues it from his sanctum.

The Medical Digest.

FRENCH NOTES.

BY A. E. ROUSSEL, M.D.

THE USE OF THE BROMIDES ON CHRONIC METRITIS (Jules Chéron).—It is incontestible that the continued use of the bromides is of great utility in all the congestive conditions of the utero-ovarian system; it often results in marked benefit.

The author has established that the bromide of sodium acts especially on the general nutrition, that the bromide of ammonium is especially useful in cerebral excitation, and that the bromide of potassium is the best moderator of the lacito-motor function of the cord. To extinguish the reflexes arising from the genital apparatus, to combat the vaso-motor paralysis arising from the lumbar region of the cord, and of the sympathetic in the same region; in a word, to remove the uterine congestion, as well as the reflex troubles due to chronic metritis, it is to the potassium salt that we shall give preference.

It is not necessary to combine, in the case abovementioned, the bromides of sodium and ammonium with the bromide of potassium.

The medicament should be used continuously for several months, and should not go above 30 grains a day.

The formula which the author employs is the following:

℞.—Bromide of potassium ..... 300 grains.
Distilled water ..... 9 ounces.

Take a tablespoonful, or a wineglassful, after each of the two principal meals.

—*La Médecine Moderne.*

USE OF THE BROMIDES AND THE IODIDES BY MEANS OF ENEMA.—Kobner recommends the following formula for patients who cannot support suppositories :

℞.—Iodide of potassium ..... 45 grains.
Bromide of potassium ..... 35 to 45 "
Extract of belladonna..... 5 "
Water ..... 7 ounces.

M.—Mix, each time, 6 drachms of this solution with from 2 to 4 ounces of hot water; at first once a day, afterward twice daily.

Later on he increases the doses, and prescribes :

℞.—Iodide of potassium ..... 150 grains.
Bromide of potassium ..... 100 "
Extract of belladonna..... 10 "
Water ..... 10 ounces.

Seven drachms of this solution in from 3 to 4 ounces of water twice daily, by enema.

Kobner finds that by adding to each enema 5 to 10 drops of pure tincture of iodine, the mixture is very efficacious, and very well tolerated by the large intestine. He has never observed any resulting inflammation.

The author has used this method of treatment in certain hypertrophic metrites as well as in syphilitic ulcerations of the rectum which had not been ameliorated by astringents or by disinfectants.

But he has more especially employed the treatment in syphilitics who could not support the internal use of the iodides. The therapeutic action of these enemas, even in doses of from 7 to 15 grains, has been very rapid. These enemas, combined with mercurial friction, may replace all other forms of medication, and are better supported than sub-cutaneous injections.—*Gazette de Gynécologie.*

A NEW TREATMENT OF HABITUAL CONSTIPATION (Flatau).—The medicinal treatment of habitual constipation does not, generally, produce very favorable results, consequently we have had recourse, in these late years, to other methods, such as massage, gymnastics, electro-therapeutics. These methods themselves generally result unfavorably. I therefore think it worth while to point out a medicament which has succeeded very well in a series of similar cases. I insert or insufflate on the mucous membrane of the rectum a pinch of powdered boric acid. I use the above at first every two days, and later on less often. I have obtained by this proceeding remarkable cures in old cases previously treated by other means without result.—*La Médecine Moderne.*

TWO HUNDRED AND SEVENTY TWO CASES OF ALBUMINURIA (Goodhart).—The author has studied a form of congestive albuminuria observed in people who eat and drink to a great extent, and who have a hereditary gouty history. The specific gravity of the urine is increased. Complete cure by diet, hygiene, and purgatives.

In neurasthenics we occasionally find an intermittant albuminuria, probably following an attack of oxaluria or of dyspepsia.

Occasionally albuminuria alternates with glycosuria, or with an excessive elimination of uric acid.

Acute nephritis may exist without anasarca, and pass unnoticed in children.

Nephritis in scarlatina may exist for a long time without alteration of the general health.

—*Journal de Médecine.*

NEW REAGENT FOR ALBUMEN (*Pharm. Centralbl.*).—Albumen is precipitated by salicylsulphonic acid in form of a white powder with acid reaction, which becomes of an intense red color by the addition of ferric chloride. The reaction is so delicate that we may recognize 0 gr. .0005 in 10 c. c. of liquid.

Journal de Médecine.

APPLICATION FOR ANGINA (H. Rousseau).—

℞.—Borate of soda,
Chlorate of soda.....āā 30 grains.
Pure glycerine..... 120 "
Honey of roses ..... 60 "

Apply with brush, five or six times daily.

Journal de Médecine.

ANTISEPTIC TINCTURE FOR DIPHTHERIA (Osiecki).—

℞.—Tincture of ratanhy ..... 150 grains.
Tincture of benzoin ..... 75 "
Tincture of aloes ..... 45 "

Apply with brush, three times daily.

After which, the following powder is insufflated :

℞.—Tannic acid ..... 30 grains.
Sublimed sulphur,
Chlorate of potash.....each 45 "

Journal de Médecine.

APPLICATION FOR BURNS OF THE FIRST AND SECOND DEGREES.—

℞.—Tannin ..... 150 grains.
Alcohol ..... 150 "
Sulphuric ether..... 1200 "

Mix.—Apply with brush.

Journal de Médecine.

PYOKTANIN AGAIN.—Dr. F. Kubli, of St. Petersburg, has repeated Professor Stilling's experiments with pyoktanin, that is, anilin yellow and anilin violet, in the treatment of various forms of inflammation of the eyes, both acute and chronic, but, unfortunately, with very different results, as in no case did the pyoktanin solution appear to have any effect in lessening the inflammation. It was also tried, with no better results, as a prophylactic on the sound eye, where the other was the subject of acute inflammation.—*Hospital Gazette.*

ONE reason why electricity so often fails in the hands of the general practitioner is because of the inadequate apparatus made use of and the insufficient methods of application. A physician should have at his command a complete medical outfit. He should have a galvanic battery capable of giving him always 50 volts and, better, 100 volts, E. M. F. ; a good Faradic battery, and a first-class static machine. It will be well if the apparatus is so constructed that the Faradic and galvanic batteries can be combined. He should be able to use those three different forms of electricity, because it is often advisable to change from one to the other, according to the effect produced. In circuit with the galvanic current should be a good rheostat, for regulating the current, and a good galvanometer.

—Prince, *College and Clinic Record.*

PREVENTION OF "BLACK EYES."—Practitioners who number many football players or members of the Pelican Club among their patients may be glad to know of the following remedy, which an American contemporary vaunts as the "sovran'st thing on earth" for bruises of all kinds. The preparation consists of the tincture or a strong infusion of capsicum annuum, with an equal bulk of gum arabic, to which a few drops of glycerine are added. This should be painted over the injured surface with a camel's-hair pencil and allowed to dry on, a second or third coating being applied as soon as the first one

is dry. If this is done as soon as the injury is inflicted, we are assured that the blackening of the bruised tissue will "invariably" be prevented. The same remedy is recommended as having "no equal" in rheumatic stiff neck.—*British Med. Jour.*

FOR GASTRIC CATARRH.—

℞.—Argenti nitratis . . . . . gr. j.
Ext. belladonnæ . . . . . gr. iv.
Ext. opii . . . . . gr. iij.
Manæ . . . . . q. s.
M.—Ft. pil. No. xxx.
S. One pill one and a half hours after meals.

OINTMENT FOR FISSURE OF THE ANUS.—

℞.—Boric acid . . . . . 3 parts.
Chlorohydrate cocaine . . . . . 1 "
Lanoline . . . . . 30 "

To be used after thorough cauterization of the parts with silver nitrate.—*L'Union Médicale.*

TREATMENT OF GONORRHŒAL ARTHRITIS.—

℞.—Camphor . . . . . 100 grains.
Extract of opium . . . . . 75 "
Alcohol . . . . . 1 drachm.
Extract of belladonna . . . . . 75 grains.

This is to be made into a cataplasm and applied over the part from ten to twelve hours, the joint being made immobile by proper dressings.
—*Journal of Pharmacy.*

AN OPERATION FOR PROMINENT EARS.—An undue prominence and turning forward of the pinna is a very unsightly deformity that is only with difficulty overcome by the methods usually employed. Dr. Ely, some years ago, treated a case of this kind by removal of an oval vertical segment of the pinna. But Dr. W. W. Keen, of Philadelphia, has improved upon this by removing an oval piece of the skin of the back of the ear, and cutting a vertical notch only in the cartilage. The skin wound is then closed with fine sutures, a bend occurs in the pinna where the cartilage has been notched, and so the prominence of the ear is remedied. The advantage of this plan is that it leaves the ear without any scar in front—without any visible scar, in fact. The case in which Dr. Keen did this operation is recorded, and the patient figured in the Transactions of the Philadelphia County Medical Society. The operation in that case was eminently successful.—*Lancet.*

DEATH UNDER CHLOROFORM.—A case of death from chloroform, of some interest, is reported to have occurred in St. Thomas Hospital recently. The patient was the subject of pyo pneumothorax on the right side, which had lasted over a year. Portions of his ribs had on several former occasions been removed under chloroform, without the occurrence of any bad symptoms from the anæsthetic. The cavity showed signs of contracting, and the discharge was still very profuse. It was decided to explore the wound, and if possible reduce the size of the cavity by rib resection. The patient was anæsthetized, and when sufficient chloroform had been given, before the dressings were removed from the wound, his pupils suddenly dilated, and both heart and respiration ceased almost instantaneously. All efforts to restore him proved unavailing. At the necropsy the heart was found to be healthy, but had been displaced somewhat to the right side. It seems probable that the patient died of cardiac failure, the death being accelerated by the diseased condition of the lungs.—*Lancet.*

MASSAGE IN HEADACHE.—Dr. Norström, finding that a good many cases of headache occur where, though the symptoms are more or less like those of migraine, the remedies suited to that affection are of but little use, examined the heads of such patients carefully, and came to the conclusion that the pain must depend upon inflammatory thickenings existing at the insertion of various muscles, especially the sterno mastoid, the temporal, the scaleni, the trapezius, and the occipito-frontalis. These indurations do not usually produce any local pain, and therefore are generally unnoticed both by physician and patient. They are commonly the result of "taking cold," and the headaches they cause can be traced to changes in the weather. Dr. Norström obtains excellent results by regular massage of these indurated spots, the sittings lasting for about a quarter of an hour. Similar treatment is also efficacious where the headache is due, as it sometimes is, to enlarged lymphatic glands. Of course, little result can be expected from massage in headaches of anæmic or of hysterical origin, or where there is organic cerebral disease.—*Lancet.*

THE TEST OF DEATH.—It has been recently stated that a prize offered some years ago for the discovery of some means whereby the inexperienced might at once determine whether in a given case death had or had not occurred, was won by a physician who had discovered that if a light were placed behind the hand of the supposed dead person a scarlet tint would be apparent where the fingers touched each other if life was not extinct; and that if no red glow was visible death had taken place, says the New York *Telegram.* Dr. W. B. Richardson has written an essay in which he states that, although this test has its value, it is not by any means to be trusted as an unfailing indication of life or death. He gives the case of a person in a state of syncope to whom the test was most carefully applied. Not the faintest sign of red coloration between the fingers could be traced, yet the recovery of the syncope was complete, and was effected without any artificial aid. Dr. Richardson regards it as a good test, but is of opinion that more certain proofs are: The pulsation; the respiratory murmur; pressure on veins; the electric test for muscular irritability; the ammonia hypodermic test; coagulation of blood in the veins; rigor mortis and decomposition.

THE therapeutic value of climate has received more and more attention for the last twenty-five years, and its benefits are more and more clearly seen and taken advantage of; and as our knowledge is extended and more accurate, and correct observations are made as to the adaptability of the different climates to the different affections, the more benefit will be derived from this therapeutic agent.

It is a pretty well-established truism that what is curative in one person is not so in another, and this is true in climate as well as in reference to articles in the materia medica.

In my practice in the East one or two office visits, at the outside three or four, sufficed to allow the patient to dispense with his medical adviser, but not so here in the majority of cases. I also discovered the class of remedies I had used East were of little benefit here, and, in fact, in many cases actually made matters worse.

The best was a tonic course of treatment with extreme care on the part of the patient to keep from adding to his disease by "catching fresh and repeated colds." But quite a proportion of patients would not get well with any remedies, and had to be sent to the

interior—to Romona, Julian, and other places—to a higher altitude and dryer climate.

This was the experience not only of myself, but quite a number of other physicians with whom I talked. Most of these patients got relief in a very few days, soon recovered, and returned. Others had to spend a longer time for complete restoration.

—Gundrum, *Thérapeutic Gazette.*

BINIODIDE OF MERCURY.—The biniodide of mercury, in common with other salts of that metal, possesses derivative and germicidal properties which are enhanced I consider, tenfold, by its solubility in solutions of the iodides of potassium and sodium, because by the great diffusion and penetrating power of those solvents, and especially of the sodic form, every corner of the circulation can be reached by the internal administration of the germicide, and skin and mucous membrane, fascia, muscle and bone pierced to destroy any invading germs from without. This powerful germicide, carried by its penetrating sodium iodide vehicle, may be effectively used locally in the following disorders:

1. Purely local germ diseases: Ophthalmia neonatorum (1 in 3,000) and contagious conjunctivitis; gonorrhœa (1 in 5,000 to 6,000); hay asthma (1 in 2,000); alopecia (1 in 500); scabies (1 in 400 or 500); ringworm (1 in 4 or 5) and sycosis.

2. Purely local septic disorders: Ozæna (1 in 3,000 or 4,000); otorrhœa (1 in 2,000 or 3,000); pelvic abscess (1 in 2,000) and pyosalpinx (1 in 2,000 or 3,000).

3. Surgical and puerperal septicæmia from infective areas.

4. At the seat of the lodgment growth and development of specific germs (1 in 2,000). Thus in the mucous membrane of the mouth and throat in scarlet fever and diphtheria; and the nose, eyes, and air passages in measles and whooping-cough.

Internally the biniodide may be given alone in pill or powder, or in solution of the liquefacient iodide, according to the nature of the disorder under treatment. The peripheral or central site of the infecting germ area has a distinct bearing upon treatment by the biniodide. Scarlet fever for instance, in that it has origin peripherally in the tonsillary region, and is not as a rule accompanied by any internal congestion at its onset, may be aborted by the biniodide in potassic or sodic iodide; whilst measles, in having a central origin in the bronchial system, should be treated without any liquefying agents whatever, by prescribing the biniodide in powder with sugar, and giving iron with peripheral vascular stimulants, such as the spirits of nitrous ether, for in no disorder of this nature is the tendency to the development of malignancy so marked as in measles and in all morbid conditions characterized by cyanosis and any degree of collapse or asthemia, it is well known the fibrine elements of the blood are deficient.

The germicidal and anti-fermentative properties of the biniodide have proved of great service in my hands in the treatment of flatulent dyspepsia, cholera infantum, English cholera, and the green stools of infants and young children.

But the *alterative* or *derivative* uses of the drug are perhaps of even greater importance than the germicidal, because of the constant occurrence of cases of peripheral and periphero-central vascular derangement in general practice. I refer more especially to the latter, in the shape of inflammatory and chronic congestive affections of serous membranes: Meningitis, pericarditis, pleuritis, peritonitis, and neuritis. In serous membranes, as elsewhere, the inflammatory process passed through the stage of congestion, stasis, effusion of inflammatory lymph, and resolution either sooner or later.—Illingsworth, *Provincial Med. Jour.*

Medical News and Miscellany.

DR. B J. WEYLL, a well-known citizen of Camden, died last Saturday, in his eighty sixth year.

THE demand for the Koch hypodermic syringes is so great that the manufacturers are unable to fill all their orders.

THE inhabitants of St. John's, Newfoundland, appear to be suffering from severe epidemics of both measles and diphtheria, the mortality from each of which is stated to be very high.

AS a reward for Prof. Koch's services in the interests of medical science the Emperor will probably confer a title of nobility upon him. He has already been decorated with the order of the Red Eagle.

PROF. KOCH states that the government must prepare the "lymph" used in the cure of tuberculosis. He also asserts that the recurrence of tuberculosis after treatment by his method is extremely rare.

ACCORDING to the *Drug, Oil, and Paint Reporter*, the general tendency of the McKinley tariff bill, while purporting "an act to reduce the revenue and equalize duties on imports," has raised the duty on drugs ten to twenty per cent.

A THIRD Medical Clinic has been established in the University of Vienna, of which Professor Leopold Schrötter Von Kristelli has been appointed head, with the rank and title of Ordinary Professor of Special Medical Pathology and Therapy.

THE city physician of Woburn, Mass., was cowhided in his office, on November 19, by the wife of a letter carrier, who is a good sample of a well-built and athletic female. The charge made against the physician was breach of professional etiquette and slander.

ACCORDING to the most recent information, there is now a considerable abatement of cholera in Spain. Some cases still occur at Valencia; the disease has recurred between Cadiz and Jerez, and also at Murcia and the adjacent villages; but at Barcelona no fresh attacks have been heard of.

DR. MURDOCH CAMERON has recently performed his fifth successful Cæsarean section at the Glasgow Maternity Hospital. He has stated that he is engaged to perform the operation in three other cases, so that, thanks mainly to his exertions, the operation appears to be gaining the confidence of the profession in the west of Scotland.

SMALL-POX attacked no less than 483 persons and caused 202 deaths in Madrid last week; the total attacks and deaths since the beginning of the outbreak being now 1,933 and 659 respectively. In certain parts of France, and notably in Brittany, this disease is also extending, and M. Proust states that it is practically endemic in the more Breton towns and villages, where both infantile vaccination and revaccination at adult age have long been much neglected. The committee controlling public health in France have unanimously decided that the time has come to make both primary vaccination and revaccination compulsory throughout the country.

A NEW eye and ear institution has been started in New York. This makes six such in that city.

MARTIN, of Paris, says that the Cæsarean operation should be performed after dilation of the cervix and prior to rupture of the amniotic sac.

EPIDEMIC BLINDNESS.—An epidemic of blindness, probably hysterical, is reported as prevalent among the working-girls of Wheeling, West Virginia.

THE French steamer "La Normanaie," which arrived in New York on Monday, had small-pox on board. Over four hundred steerage passengers were detained at quarantine.

CRIMINAL abortion is very rife in France. All classes of society resort to it, and married as well. The unmarried get rid in this manner of their offspring for obvious reasons.

IT is said to be possible to restore one who is helplessly intoxicated to the almost complete use of his faculties in a very short time, by administering to him a half teaspoonful of ammonium chloride in a tumbler of water.

A NEW Sanatarium of the air-cure, so-called—the first of the kind in France—has just been opened with some ceremony at Vernet, in the Pyrenees. The site is said to combine the advantages of a mountain and of the Mediterranean climate.

MEDICAL students in London are compelled to go through a course of four years' study, hospital attendance and lectures, before being qualified to appear for the final examination. By an order of the General Medical Council of England the term of preparation has been extended to five years.

FIFTY-FIVE ladies practising medicine in India have presented a memorial to the Viceroy, urging that the age of consent for marriage in respect of native females should be raised to fourteen. The memorial is reinforced by notes of a number of observations in zenana and female hospital practice.

To cover defects in the bones of the skull, Jaksch transplanted plates of bone taken from the head of a goose several days old, upon the granulating dura mater. Two days after implantation, the bony plates were firmly adherent to the surface of the dura, and a week later the opening was closed by granulations.

THE AMERICAN ACADEMY OF MEDICINE.—We are requested to announce that the American Academy of Medicine, Richard J. Dunglison, M.D., *Secretary*, 814 N. Sixteenth street, will hold its annual session at the College of Physicians, Philadelphia, on Wednesday and Thursday, December 3 and 4, commencing at 10 o'clock A.M., Wednesday.

DR. J. H. MCKELLUP, who was authorized by Governor Ross to thoroughly investigate the reported existence of glanders in Texas, has forwarded his report to the Governor. It states that the only section where glanders was found to have existed was in Dewitt county, where thirteen cases occurred among horses. All the affected animals have been killed.

A HOSPITAL IN CENTRAL AFRICA.—As an instance of the civilizing work now being carried on in the Congo Free States, may be mentioned the Bangala-station hospital, in the upper Congo basin, a little less than a thousand miles from the Atlantic coast. It was erected for the employés of the station, and contains forty beds, besides rooms for convalescent patients.

IT is stated that a new journal, with the somewhat ambitious title *L' Univers Médical*, is about to appear in Paris under the editorship of Dr. Séxéno, a pupil of Dr. Apostoli's. The new periodical, and which is understood to be an outcome of the Berlin Congress, will have for its object the promotion of professional solidarity among medical men of all countries, and the furtherance of international co-operation in matters of hygienic reform.

A GOOD many people spoil the effect of a good night's rest by the ridiculously heavy bed-clothes they use. Old-fashioned cotton quilts, or modern Marsala ones, are very heavy and of no use, as a thin covering to protect blankets from the dirt is all that is really necessary. Bed-clothes should be like body-clothing—light and warm. Many a bad sleeper would do well to see whether his coverings are not at the bottom of his restless nights.

THERE could scarcely be a more striking object lesson, says the *British Med. Journal*, as to the value of vaccination if thoroughly carried out than is afforded by the example of Holland. Between 1870 and 1873 there were 20,575 deaths from small-pox in that country. A stringent law was then enacted making vaccination compulsory, with the result that the small-pox mortality has since steadily diminished from year to year. During 1890 only one death from small-pox has so far occurred in the whole of Holland.

OPHTHALMIC HINTS.—The discharge from an eye suffering from the simplest form of conjunctivitis may produce purulent ophthalmia if inoculated in another eye. Enforce the strictest cleanliness and care.

Always examine the cornea with a magnifying glass whenever there is a possibility of its being the seat of an ulcer or a foreign body.

Avoid preparations containing any salt of lead.

Never order a shade to be worn over one eye only. If one eye needs protection from light so does the other.—*Buxton.*

AN ASSAULT ON A NAVAL SURGEON IN BROOKLYN.—Dr. Delevan Bloodgood, medical director of the laboratory at the Brooklyn Navy Yard, was, on November 8, the victim of a highwayman's assault. He was knocked senseless and robbed of all the valuables he had upon his person, while returning at night to his residence near the Naval Hospital. The blow was probably given from behind by means of a sand-bag, and was only a little short of being murderous in its violence, but, fortunately, no bones were broken and no untoward symptoms have since arisen.

IMPURE ICE.—The State Board of Health, of New York, after a careful investigation of the subject, recently came to the following conclusions as to the effects of impure ice in causing disease: "Ice formed in impure water has caused sickness; it may contain from eight to ten per cent. of the organic matter dissolved in the water, and in addition a very large amount of organic matter that had been merely suspended or floating in it; it may contain living animals and plants ranging in size from visible worms down to the minutest spores, and the vitality of these organisms may be unaffected by freezing."

MÜTTER LECTURES OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The course of lectures on surgical pathology provided in accordance with the will of the late Prof. Thomas D. Mütter, will be delivered during 1890-'91, by Prof. Boswell Park, of Buffalo, N.Y. The first series of five lectures will be given in the

hall of the College of Physicians, corner of Thirteenth and Locust streets, on December 4, 5, 6, 8 and 9, at 8.15 P.M. The subjects are as follows: 1. Introductory; study of the blood and of some phases of the inflammatory process; thrombosis, embolism, hæmoglobin and oligochromæmia, ptomaines; conditions predisposing to infection. 2. A study of pus and of pyogenic organisms, obligate and facultative. 3. Surgical sepsis and the organisms which produce it; resumé of experimental work, surgical fever, intestinal toxæmia, sapræmia, septicæmia and pyæmia. 4. Peritonitis—forms and causes; testing the relative values of antiseptics. 5. Tetany and tetanus.

The medical profession are cordially invited to be present. D. Haynes Agnew, *President;* William Hunt, *Chairman of the Committee.*

WE agree with the *Hospital Gazette*, that the number of reports of deaths occurring under anæsthetics has, of late, been startlingly large. The figures are simply appalling. One cannot take up a paper without being confronted with the stereotyped formula, and this in spite of the laborious investigations of the Hyderabad Chloroform Commission. Unfortunately there does not seem to be any help for this state of things, and all that the public can demand is proof that due skill and care were shown in administering the anæsthetic. In the long run, however, the public will get frightened, and the practice of giving anæsthetics for trivial operations will come to a stop.

SPECIALISTS.—"Show me the man who can treat a square inch of the body perfectly, and I will show you a man who can treat the whole body well." You may, perhaps, say I am drawing an ideal. Not so; for I believe the specialist is *made*, not *born*. By this I mean that every specialist should have a *thorough* medical education, as well as a good deal of practical medical and surgical experience, before he launches out as a specialist, for otherwise how can he tell which branch he is best fitted for? The man who takes a six weeks' special course in surgery, genito-urinary disease, diseases of women, eye, ear, etc., is no more a specialist in that branch than a new-born babe.—*Southern Med. Record.*

AT the meeting of the Board of Charities and Correction at the Philadelphia Almshouse recently a letter was read from Dr. Daniel E. Hughes, the chief resident of the Philadelphia Hospital, relative to having the hospital supplied with Prof. Koch's "lymph" at the earliest possible moment, and requesting that a cablegram be sent to Berlin to secure a supply. The chief resident stated that no hospital in the country offered the same opportunities for a thorough test of what he considers a great discovery. There are now sixty-two patients ready at the hospital to try the "lymph," who would be closely watched, and progress reported daily. The board gave Dr. Hughes the power to order the "lymph," and make a test.

SOME of the Berlin daily papers warn the public against the illusions entertained by many regarding the efficacy of Koch's remedy. They also complain that the stock of "lymph" is being exhausted. The *Tageblatt* says that Koch's procedure so far is open to severe criticism, because he has only given his "lymph" to a few collaborators whom he could thoroughly trust to follow his instructions, while the great scientific establishments and hospitals are excluded from the benefits of the discovery. The *Tageblatt* considers that the dissatisfaction among medical men and the many patients who are anxious to submit to the treatment is quite justified, and declares that the present arrangements must be altered.

A TENNESSEE doctor is credited with delivering two children with a pair of shoemaker's pinchers, using the curved handles as obstetric forceps.

An Alabama doctor tells about a patient of his with neuralgia, who took a sharp-cornered rock and broke a hole through his cranium, and poured swamp water in to cool off his brain.

We have heard of an Eastern doctor, who, to be no whit behind his Southern brethren, claims to have delivered premature children with a pencil, or a branch of a tree.

We are now ready to hear from the man who performed an iridectomy with a monkey wrench, and a Cæsarean section with a buck saw. There's nothing like expedients when you are in a pinch.

PATENTS, ETC., on medical subjects, issued November 18, 1890:

Disinfecting device	A. R. Upward	London, England.
Blue dye	W. Majert	Berlin, Germany.
Blue-black azo dye	Lauch & Kahn	Elberfeld, Germany.
Making hydrogen peroxide	W. Erwin	Philadelphia, Pa.
Inhaler	Krohne & Sesemann	London, England.
Complexion mask	N. E. Jenkins	Auburn, N. Y.
Stomach bitters	H. W. Farrell	Noah, Tenn.
Obtaining oxygen	F. Salomon	Essen-on-the-Ruhr, Germany.

TRADE-MARKS.

Medicine for diseases of the liver and for chills. (The letters "A. C. S., Jr.," in the form of a symbol)	A. C. Simmons, Jr., Medicine Co	Sherman, Texas.
Cure for catarrh and lung and liver troubles. (The portrait of "Erie Tomlinson," deceased)	Tomlinson Dead Shot and Quick Relief Oil Co	Le Mars, Iowa.
Medical belt for the cure of diseases. (The words "Angel Girdle")	G. W. Angell	Newark, N. J.
Ozone-water. (The representation of two serpents and the words "Anti-bakterikon")	Ozone Mfg. Co	New York, N. Y.
Anti-febriles. (The word "Phenacetin")	Farbenfabriken, vormals Fr. Bayer & Co	Elberfeld, Germany.

LABELS.

"One Minute Toothache Cure"	L. F. Segrist	Philadelphia, Pa.
"Dr. Buxton's Cough Syrup"	F. E. Buxton	Boston, Mass.
"Dr. Welch's Gold and Platina Alloy" (for dental purposes)	The Wilmington Dental Manufacturing Co	Philadelphia, Pa.
"Standard Gold Cylinders, Style O," (for dental purposes)	R. S. Williams	New York, N. Y.

—CHARLES J. GOOCH, *Patent Attorney.*
LOCK BOX 76, WASHINGTON, D. C.

DR. J. G. ORTON, as President of the New York State Medical Association, has offered a prize of $100 for the best short popular essay on some subject connected with practical sanitation, under the following conditions:

1. Competition to be open to all.

2. Essays to be forwarded to the Secretary of the Association, Dr. E. D. Ferguson, Troy, N. Y., not later than August 1, 1891, accompanied by the name of the author under separate seal.

3. Examination and award to be made by a committee appointed by the Council of the Association.

4. The successful essay to be read at the next annual meeting of the Association, and, if approved by the Council, to be offered for publication in the secular press, and issued in tract form or otherwise for general circulation.

5. Authors of essays, unsuccessful as far as the prize is concerned, but found worthy of special commendation, to receive intimation as to a proper disposition to be made of them.

BONES.

An Osteological Study.

I'm trying hard my bones to read,
And o'er their forms to ponder;
But every time I sit me down
My thoughts begin to wander.

Now first of all I take my skull
(For that I'm very dull in),
But very quickly I find out
That I'm no good at sculling.

Each diff'rent kind of vertebra
To my poor mind a tax is;
For in the atlas there's not marked
The outlines of the axis.

Now, Quain I have thee "on the hip,"
I think you are to blame, Sir;
The bone that's called innominate
Must surely have a name, Sir.

The ankle bones are seven in all,
In fact there's quite a parcel,
Then follow five which got their name
Because each met a tarsal.

They say there are no funny bones,
Yet queer ones are so numerous
That I am not surprised to find
At least there's one called humerus.

H. W. LANE, in *Hospital Gazette.*

HERMAPHRODITISM.—Dr. C. W. Fitch reports in the *New York Med. Journal* the following interesting case of hermaphroditism: "The case was brought to my notice by the commandant of police of San Salvador, Salvador, C. A., while I was in charge of the sanitary service of said Government. As it is a unique case, I should like to have it reported, with a view of ascertaining whether a similar case has ever been seen. J. H., a house servant of masculine features and movements, aged twenty-eight, height five feet seven inches, weight one hundred and thirty-nine pounds, was arrested by the police for violation of the law governing prostitution, which compels prostitutes to register with the Direction-General of Police, and pass a weekly examination by a surgeon detailed for that purpose. On examination, both female and male organs of generation were found in a remarkably well-developed condition. The labia majora were of normal size, but flattened on their anterior surface. The labia minora and the hymen were absent. The vagina was spacious, four inches and a quarter long anteriorly, and six inches posteriorly. The os uteri was torn on the left side. There was profuse leucorrhœa. Seven years before, she had given birth to a normal female infant. In place of the clitoris there was a penis which, when in erection, measured five inches and a quarter long by three inches and five-eights in circumference. The glans penis and the urethra were perfectly formed. The scrotum, which was two inches and an eighth long, contained two testicles about an inch in length and two inches and a half in circumference. The mons Veneris was sparsely covered with short, straight, black hair. Both sets of organs were perfect in their functions, semen being ejected from the penis, and the ovaries being capable of producing eggs. Scanty menstruation occurred every three weeks, and lasted but two days. Sexual gratification was said to be equally distributed between the two sets of organs.

"Up to about seven years before, masculine clothes had been worn, but when pregnancy became apparent, the local authorities compelled a change to female attire."

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy and Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from November 10, 1890, to November 17, 1890.

By direction of the acting Secretary of War, leave of absence for three months is granted Captain Charles M. Gandy, Assistant-Surgeon U. S. Army, Fort Clark, Texas. Par. 10, S. O. 266, Headquarters of the Army, A. G. O., November 13, 1890.

Leave of absence for one month, to take effect on or about the 15th instant, is granted First Lieutenant Freeman V. Walker, Assistant Surgeon, U. S. Army, Fort D. A. Russell, Wyoming. Par. 3, S. O. 85, Dept. Platte, November 11, 1890.

By direction of the Secretary of War, the leave of absence granted Major Stevens G. Cowdney, Surgeon, in Special Orders, No. 112, October 24, 1890, Department of Arizona, is extended fifteen days. S. O. 263, Headquarters of the Army, A. G. O., Washington, November 10, 1890.

By direction of the Secretary of War, the extension of leave of absence on account of sickness, granted Major Henry McElderry, Surgeon, in Special Orders, No. 214, September 12, 1890, from this office, is further extended two months on surgeon's certificate of disability. Par. 28, S. O. 263, A. G. O., November 10, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending November 15, 1890.

OWENS, THOMAS, Surgeon. Ordered to the Museum of Hygiene at Washington, D. C.

MARTIN, H. M., Surgeon. Detached from the Receiving ship "Wabash," and ordered before Retiring Board.

RIXEY, P. M., Surgeon. Continued in charge of Naval Dispensary at Washington, D. C., until November 20, 1890.

GREEN, E H., Past Assistant-Surgeon. Promoted to Surgeon, November 10, 1890.

SMITH, HOWARD, Surgeon. Placed on the Retired List, November 10, 1890.

EDGAR, J. M., Past Assistant-Surgeon. Ordered to the U. S. S. "San Francisco," November 10, 1890.

SPRATLING, L. W., Assistant Surgeon. Ordered to the U. S. S. "San Francisco," November 10, 1890.

WHITE, CHAS. H., Medical Inspector. Ordered to the U. S. S. "San Francisco," November 10, 1890.

SCOTT, HORACE B., Past Assistant-Surgeon. Placed on the Retired List, October 31, 1890.

ASHBRIDGE, RICHARD, Past Assistant-Surgeon. Surveyed and sent to hospital, Philadelphia, Pa.

KENNEDY, R. M., Assistant-Surgeon. Detached from Navy Yard, League Island, and ordered to U. S. Training ship "Richmond."

ATLEE, L. W., Assistant-Surgeon. Ordered to the Navy Yard, League Island, Pa.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the three weeks ending November 15, 1890.

CARTER, H. R., Past Assistant-Surgeon. Granted leave of absence for fifteen days, November 14, 1890.

GUITERAS, G. M., Assistant-Surgeon. Granted leave of absence for thirty days. October 29, 1890.

HUSSEY S. H., Assistant-Surgeon. To proceed to South Atlantic Quarantine Station for temporary duty. October 28, 1890.

GEDDINGS, H. D., Assistant-Surgeon. Granted leave of absence for fourteen days. November 14, 1890.

GROENEVELT, J. F., Assistant Surgeon. To report to the Superintendent of Immigration for temporary duty. October 28, 1890.

The Times and Register.

Vol. XXI, No. 23. NEW YORK AND PHILADELPHIA, DECEMBER 6, 1890. Whole No. 639.

CUPRIC ARSENITE FOR AFTER-PAINS. By Boardman Reed, M.D., Atlantic City, N. J. 519

CUPRIC ARSENITE FOR AFTER-PAINS.

BY BOARDMAN REED, M.D.,
ATLANTIC CITY, N. J.

THE arsenite of copper has recently won a place as a remedy of value in certain neuroses and other affections of the alimentary canal. I herewith submit a report of six cases in which it was administered for the after pains following labor. In four of these it acted very favorably, in one effected slight improvement, and in one failed entirely.

CASE I.—A married lady, aged thirty-two years, after her fifth confinement in February, 1889, had most persistent and severe after-pains, which resisted entirely all the usual remedies. Quinine, cimicifuga, paregoric, and finally morphine were tried in succession, the last in full doses, without affording more than temporary relief. The trouble had gone on some five days, and was seriously menacing the patient by interfering with her rest and nutrition, when I happened to think that the arsenite of copper, in minute doses, having shown in my hands remarkable antispasmodic virtues, in colics and cholera morbus, might be of service in these evident spasms of the uterine muscle. I ordered it in about 1-1000 grain dose every half hour, with the result of a rapid and complete relief. The pain soon ceased entirely and did not return thereafter.

CASE II.—August 2, 1890, I attended Mrs. G., aged thirty-seven years, in her sixth confinement. Labor was normal in every way, and of short duration. Some six hours subsequently the patient had a fainting attack, due mainly to the fact that, following out the prejudice of former days, her nurse gave her no supper, except a cracker and a cup of tea; and the further fact that the members of her very numerous family and connection insisted on congratulating her up to the hour of midnight, and thereby greatly fatigued her. Rallying from the attack of syncope, she complained of after-pains, which, for two days, distressed her greatly. Paregoric was first given, and this afforded her only slight relief. Morphine was tried in full doses, with only temporary amelioration of the pains. The trouble proving so obstinate, I bethought myself of the arsenite of copper. Two of Wyeth's tablets of 1-200 grain each were dissolved in a small half tumbler of water, and one teaspoonful was given every half hour. This was at my first visit, at 11 A. M; at the evening visit the patient reported that the pain had been speedily cured, and she had been free from it the greater part of the afternoon. It did not recur.

The patient in each of the foregoing cases was somewhat nervous. There can be no question that the relief afforded was *propter hoc* and not merely *post hoc*, since it followed so closely on the administration of the remedy, and proved lasting. It may interest many busy practitioners to learn that so simple and, in suitable doses, so harmless a medicine, can prove so efficacious, even after our powerful, but much abused old friend, morphine, has failed.

CASE III.—A married lady, aged thirty-six years, during her fifth pregnancy became affected with albumenuria. In August last at about the seventh month she was delivered of a dead child after a short and not difficult labor. After-pains came on at once, and somewhat severely. Owing to the condition of her kidneys, opiates were contra-indicated, and I resorted at once to the arsenite of copper, giving her, as before, about 1-1000 grain every half hour. She was promptly relieved and the pains were controlled so long as she took the medicine. During the night this was suspended, and, as a consequence, the pains returned in full force the next morning. She then resumed the medicine with the same palliative effect as on the previous day. It was kept up more or less regularly during the day, and controlled the

pains so completely that she made no further complaint about them.

CASE IV.—Mrs. B., aged twenty-four years, pregnant for the second time, was delivered August 20, at term, of a large boy, after a phenomenally short and easy labor. Dr. W. B. Stewart, my assistant, was summoned to the case first and, after my arrival, assisted me in the management of it. After-pains coming on sharply soon after delivery, I administered the arsenite of copper in substantially the same manner as already detailed in the previous cases. When Dr. Stewart made a second call, late in the evening, he found that only partial relief had been obtained. The pains had been rendered somewhat less in severity and the intervals between them lengthened after the administration of the remedy; but the patient, who was an over sensitive lady, was still much disturbed by them. Dr. Stewart, therefore, increased the dose in the hope of obtaining greater effects. Next morning, the pains still giving her some trouble, morphine was administered with entire success.

CASE V.—A married lady, aged twenty-eight years, was attended by me in her third confinement. Labor was extraordinarily rapid—the first stage lasting only two or three hours, and the second stage only a few minutes; the child, a thirteen-pound boy, having been born before I arrived. There was a considerable tear of the perineum, which I closed at once. After-pains came on in a severe form, shortly after delivery, and persisted, in spite of my usual doses of the arsenite of copper, until full doses of chlorodyned were taken.

It is noteworthy that, in case five as well as in case four, the tablets of the arsenite employed were of a new lot, from a different manufacturer. It was found very difficult, indeed almost impossible, to make them dissolve, and this may account for the failure of the remedy in these cases.

The following case has been kindly contributed:

CASE VI, by W. B. Stewart, M.D.—On September 7, 1890, I was called to attend Mrs. B., a colored woman, in her fifth confinement, and delivered her of a large girl baby. She began to complain of after-pains shortly after the labor was over, and they became so severe that relief was necessary. I dissolved $\frac{1}{100}$ grains of the arsenite of copper in a half tumbler of water, and gave her one teaspoonful every ten or fifteen minutes. After the third dose the pains were very much relieved, and the next morning the medicine was discontinued, as the pains had ceased to be annoying. They have not sinced returned.

We need a greater variety of remedies for pain, and should welcome additions to the number of those that can be safely administered for its relief. So far as has yet appeared, I was the first regular physician to make a systematic trial of the arsenite of copper in spasmodic pains—especially colic and cholera morbus. My results were communicated to my friend, Dr. John Aulde, of Philadelphia, Pa., and led him to make a trial of the drug, as was kindly mentioned by him in his first papers on the subject. Dr. Aulde deserves all credit for first calling the attention of the profession to this important remedy. He has since written it up so extensively and industriously that it is now a generally recognized therapeutic agent, and already finds a place in the catalogues of our manufacturers of those elegant and convenient little pharmaceutical preparations known as tablet triturates.

Many other physicians in this country, and some very prominent ones in Europe, have since used the drug successfully, and reported their results. So far as I have observed, however, no one of them has yet given an explanation of the *modus operandi* of small doses of arsenite of copper in curing vomiting, diarrhœa and violent colicky pains in the alimentary canal, as well as cramp pains in other parts, when the physiological effects of the remedy are known to be violently irritating.

The arsenite of copper contains, in each 100 parts, 52.8 parts of arsenic and 33.8 parts of copper. The choleraic effects of toxic doses of arsenic are familiar to all. As to copper, which constitutes more than one-third of the drug, Prof. H. C. Wood's Therapeutics is authority for the statement that it causes "violent vomiting and purging, accompanied by severe colicky pains;" and Blyth, in his work on "Poisons," names, among its effects, besides vomiting and purging, such "affections of the nervous system as spasms, cramps, paralysis and even tetanus."

Now, as the gentlemen who have been writing so ably about the arsenite of copper have, so far, not explained how the small doses employed have exerted curative effects directly opposite to those well-known to results from toxic doses of the same and of its constituent metals, there is danger, on the one hand, that many physicians will disbelieve the reports; and, on the other hand, that our Homœopathic brethren will claim the cures as exemplifications of their incomprehensible and altogether unscientific dogma of *similia similibus curantur.*

Hence, it seems to me wiser to explain that all such curative effects of comparatively small doses of medicines, including the familiar use of two-grain doses of quinine as a tonic, when drachm doses of the same will depress and almost paralyze the nervous system, are instances of the general principle that all tissue-disturbing remedies, whether drugs, massage, electricity or hydropathic measures, are capable of exerting two opposite effects according to the dose administered. The effects of the small dose are opposite or antagonistic to the effects of the large dose, and, therefore, antagonistic to such diseases or lesions as are capable of being produced by the large dose.

For instance, large doses of quinine are capable of causing profound debility. Therefore, small doses of quinine may be depended upon as a remedy to antagonize and thus cure debility. In like manner digitalis, in the largest doses, or pushed too long even in moderate doses, is capable of depressing the heart, finally, as demonstrated by Nothnagel and Rossbach, causing it to stop, in the case of warm blooded animals, "paralyzed in diastole." Therefore, small or moderate doses of digitalis, not continued too long, may be depended upon to antagonize cardiac weakness. There is no *similia similibus* about it, but always *contraria contrariis.* All of us are constantly using scores of remedies in this way, and the same may be said of the physicians who practised hundreds of years before Homœopathy was invented.

The subject of the twofold action of medicines was fully discussed by me in the *London Practitioner* for April and May, 1888; in the *Therapeutic Gazette* for October, 1888; and in the *Medical and Surgical Reporter* of November 24, 1888.

DR. LASSAR, Secretary of the Tenth International Medical Congress, ran away from Berlin to escape the consequences of treating the Empress badly while conducting her through the exhibition. It is also said that his official statements were incorrect. Lastly he is said to be insane.

THE PSYCHICAL ASPECTS OF INSANITY.[1]

By JOHN SHRADY, M.D.,
NEW YORK.

SOME one has said that in nature there is no such potentiality as uniformity, that even two clover leaves are not alike, and how, in speaking of the human race, can a divergence or exception to a condition like this be expected? Each individual, then, has a tendency which forbids a copy or imitation, and by this he is recognized even though he may have been brought under the influence of the identical surroundings of his brother or neighbor. Police officials say that every criminal has his style. Hence, why need a reference be made to the various recognizable scripts of the pupils trained by the same master? These are truisms which are readiest at hand. These are the signatures which to the individual are as the symbols of the mathematician—convenient condensations of long statements.

A further step in the argument may be taken by granting that there can be no standard of capacities or individuals, for what might be the acme in one could not well be in another. Still less can mind itself be measured, for who can pronounce upon a man's best work? The same may be said of moods or impulses—the one being a prolonged, the other only a fitful, evanescent condition. What the world may regard as a masterpiece may not be accepted as such by the author. Milton, for instance, ranked his "Paradise Regained" much higher than his "Paradise Lost," and honestly held to that opinion to the very last. So of others in the various walks of the arts and sciences, even where painstakings are to be taken as the criterion of excellence.

Now for the consideration of the individual. Horace Greeley is credited with the remark that the only truly honest man was the egotist—in that he feared not to express his convictions, which were to the effect that he was really the center of the universe, and that these ideas of a person's importance, though in the main unuttered, were inherent in all. This, however, is to be set down as only a partial truth, inasmuch as many are swayed by the opposite temper of the mind—self depreciation. For the better understanding of these manifestations it is necessary to concede that man begins as an infant, in whom the ambition of supplying the immediate wants of the animal is paramount. Self wields the sceptre, and if there be an arrest of mental development this will probably continue until the end.

With an individual thus in constant communion with himself there is no conception, or at least no adequate one, of the rights of others. "After me, the deluge," is the phrase which exactly characterizes the motives that actuate this class of persons, who care neither for the comforts nor for the comments of their neighbors. Here is to be found the gem of future trouble. It matters nothing whether the service is through love or fear, self is ministered to, and that is the highest expectation—it is the subordination of the will of others in tribute or acknowledgment of our own supremacy that constitutes the aim. Society, in spurning these attempted encroachments upon its eminent domain, will not yield a jot of its rights, but in various ways compels the surrender of the individual.

Now, let these habits of thought regarding individual importance prevail indefinitely, or become a demeanor of the mind, unmixed with other motives and entirely independent of them, and you have the beginnings of the invitation to insanity. Verily, can this be claimed without a challenge? As a more accurate statement, should it not be said that these may be the manifestations of the first departure from sanity? To these succeed delusions which keep self still dominant and exacting. Those symptoms, although not pronounced at the start, are capable of unlimited development. They require, however, to be indisputably chronic before they are generally accepted, for, as a rule, the world does not come in these cases to a hasty decision. If at all, the error is on the side of explanation, and invariably the judges are loath to accede to a conviction without facts.

But these suspects now under discussion require watching, and the prognosis is at all times beset with doubts. The retrospect, as usual, is a great expounder, and for this very reason observers delude themselves into the notion that it was prescience that begot the opinion and legitimatized the reason. Therefore, in view of these difficulties, when called upon in a case, which in a legal phrase is known as "de lunatico inquirendo," the process of examination should be subjective—the individual, as such, should never be permitted to escape mental scrutiny. He should be treated as one whose pivotal point was self-love; this is a means of gaining his confidence, so that his hallucinations may be brought to the surface. His fancies are to be humored, his lines of thought encouraged, and his vanity flattered, in order that, elated with having gained a proselyte, he may rise to the stature of a propagandist.

Not that it is necessary to descend to the arts of the detective, but that the process of unbosoming may be as complete as possible, for, be it remembered, that only by words is conviction to come. The suspect, however, has a deal of method in his madness—he wears a panoply of shrewdness and is marvelously alert—he may take refuge in reticence or in paradox, and thus interview after interview may be brought to naught. Very often the examiner himself is cross-examined, and makes at best a very sorrow witness.

Now, in the present consideration of the subject, all somatic problems are, of course, eliminated as tending towards confusion—the dealing is with the outline, not with the picture—with facts, such as are to be garnered for the use of the judge—he is to possess the wherefore. Furthermore, one point is to be kept steadily in mind, that as the functions are to the body so are the motions to the mind. Perhaps the exception that the emotions are more complex in their workings and less direct in their offices may be allowed. Again, they may be more difficult of analysis, inasmuch as the focus is at the wrong end, the divergent rays presenting themselves only as a glare to the bewildered vision. The emotions, too, are capable of an indefinite development and of a concentration, challenging conception. A certain passion may tyrannize over all the rest, and in its loyalty to self be perfectly consistent in its reign. To detect this element of discord often taxes the craft of the examiner to the utmost.

As civilization, according to a writer on the causes of lunacy, contributes to the exaltation of the individual responsibility, so also does it impose an individual wreckage. The friction is the result of the complicated machinery. There are more comforts, but there is greater strife. In savage life there is more communism, and the government being practically paternal, the responsibilities are reduced to a minimum, so that the rights of the few yield to the

[1] Read before the New York State Medical Association, October 24, 1890.

expediencies of the many. The brief hour fumings become merged into the melancholy and mania of the individual victim. The person becomes the center for all kinds of delusions, running the gamut from self-exaltation to self-depreciation. As has been before inferred, investigations are, therefore, to run along these lines.

It cannot but be conceded that it is difficult to follow a principle without the idea of a personality, hence the borrowing of analogies from the external and the palpable. Treated as entities, passions in conflict lay at the root of the ancient mythologies, and thus the vagaries of the lunatic were clothed with personified attributes. The developmental theory is to be followed through its ramifications. There is to be a pitting of motives, one against the other, the degrees of passions are to be followed as the acts of a tyrant. The stages of admiration are to be traced clean through up to the zenith of adoration, self depreciation onward to suicide, rage to murder, politics to supreme control, love to complete ownership, and ambition to omnipotence.

If reason and a respect for the rights of others assert themselves, even to a degree, the disillusion comes, and despair becomes an inseparable spectre. There is a deal of truth in the swing of the pendulum, so often used as a figure of speech. The gentle Ophelia sings ribald songs, which a modern audience will not tolerate, even though linked to an exquisite melody. Hawthorne effectively uses it in his "Scarlet Letter," when he makes the guilty clergyman yearn to hiss oaths into a sailor's ear. The culprit carries to the verge of the gallows the burning wish to "die game." Since he has failed in the matter of reputation, he is content to pass its counterfeit of notoriety. The officer in disgrace falls upon his own sword, even as the hero accepts martyrdom, without a murmur. But these are samples only of a degree; carry them into insane or criminal life, and how deplorable the consequences! The murderer reasons that the penalty for the added crime of suicide can be no greater, and the charity of the moralist suggests that only his premises were wrong and his logic at sea.

The majority of mankind, in their disinclination to think, content to be led merely by vagaries, soon lose their power of will, and are quite willing to be driven by every wind of doctrine. Let them be impressed with the idea that it is impossible for them to err, and they soon drift into the delusions of grandeur. Will has then no control; consequences are disregarded, and thus a mission subconsciously created waits for a denouement. Self-complacency may be classed as a leading mental feature of the insane, and, when the loss of self-regulation be added, they may be regarded as utterly hopeless cases. This acceptance of their lot may be regarded as a symptom of evil import. Henceforth no amount of rational appeal can be expected to be effectual. As somatic causes produce delirium, coma, and paralysis, they have not been considered in the discussion; so, also, the forms of brain deterioration. The dealing has been with the symptoms, not with the pathology.

In treatment, the principles of Dr. Chalmers' phrase, "the expulsive power of a new affection," should be followed out; in other words, one mood should crowd out another and more dangerous one. This was the father of the idea of substitution, based upon the fact that recreation came from the alternating rest of opposing muscles. Concentration upon any given subject of contemplation is to be avoided, diversion being the rule. Nothing can be expected from medication in its restricted sense, because hygiene and variety of employment or amusements constitute by far the best course. These are the principles which govern the management of the insane in the asylums of civilized life, and many are the devices to turn the currents of thought from channels that are worn and grooved.

THE RELATIONSHIP OF NASO-PHARYNGEAL DISEASE AND CATARRH OF THE MIDDLE-EAR.[1]

By D. EMMET WELSH, M.D.,
GRAND RAPIDS, MICH.

THE relationship existing between naso-pharyngeal disease and catarrh of the middle-ear is intimate and inseparable. The ear depends upon a healthy condition of the nares and naso-pharynx for the healthy performance of its function. Ophthalmology and otology have long since gone hand in hand; yet they have nothing in common, and their association is erroneous; but to ally otology with rhinology would be furthering the advance of medicine and the successful treatment of diseases of the middle-ear would be more ably accomplished. Thus, the pathological connection of these branches could be better subserved, and a more favorable prognosis given our patients.

Laryngology, as applied, has been considered to include rhinology, yet this is of sufficient importance to stand alone, or rather in a coördination of these fields, for the laryngologist cannot be successful if he eliminates bronchial conditions from his domain. Patients presenting themselves for the treatment of ear diseases, always give the story of catarrh. Where located? in the nose and throat, and date their primary impairment to this condition. Therefore it becomes necessary for us not only to become familiar with the speculum, the rhinoscopic mirror, the turning fork and catheter, Politzer bag, etc., but also to be able to detect the diseases of the nares and naso-pharynx, its inflammations, obstructive lesions, and their removal. It is not only incumbent upon the physician to be able to detect the more pronounced abnormalities of the nares and naso-pharynx, but he must be able to detect the slightest deviations, and correct them as well.

The existence of a spur on the septum may be the means of exciting a tinnitus aurium, and how useless direct medication would be to the ear without its removal. It would be entirely erroneous for the rhinologist to ignore the large number of aural complications he meets with in daily practice. This is very apparent indeed when we consider that the large proportion of abnormal changes that take place in the ear result from those diseases of the naso-pharynx which produce narrowing or obstruction of the Eustachian tube. The rhinologist and otologist have waged war against each other, and each claiming a protectorate in his own particular "ism;" the former by his treatment alone, and directed especially to the naso-pharynx, has obtained success; the latter, condemning him in that failure has occurred, due to unfamiliarity with other diseases of the ear; hence it is better, and our results more satisfactory if the medication is applied conjointly to the nares, naso-pharynx and ear.

In all cases conservatism should prevail, and if failure accrues, it is then that our surgical means

[1] Read before the American Rhinological Association, October 6, 1899, Louisville, Ky.

may be of avail, by not only restoring the parts to a normal condition, but acting as aids to hearing and as a prophylactic agent in removing the cause and giving immunity to recurrent attacks.

Repeated attacks of otitis media can be found in causes directly referable to some mechanical obstruction or inflammatory condition of the naso-pharynx. Its relief is dependent upon this causation, and its treatment plain. Yet how often do we find that this is not detected, and the uselessness of direct medication to the ear is patent. This is best illustrated in cases of children, who, after suffering from recurrent attacks of otitis media, are presented for examination and treatment, when, on inspection, the membrana tympani are found inflamed, the child suffering from difficulty in breathing, mouth-breathing predominating, the nares inflamed, and an adenomatous growth existing at the vault of the pharynx. All treatment with a view to correct the inflammation of the ear is useless, and our only plan is to medicate the nares and naso-pharynx. It is of little importance what plan is pursued in these cases, be it the cautery or snare, curette or spray medication, but the lesson taught is their relationship and acting as coördinates or dependents in the results to be obtained. Some writers claim that from atrophic rhinitis most cases of chronic non-suppurative catarrh of the middle-ear develop.

But in this, the climate of western Michigan, where the changes are sudden and frequent from dryness and moisture, atrophic rhinitis is rare, and instead we find a form of rhinitis characterized by excessive secretion of mucus or muco-pus and a chronic inflammation of the membrane. This, in middle and adult life, is so continuous and gradual that whilst the impairment of the sense of smell diminishes, it remains unattended until they perceive a defect in hearing, when, on inspection, the above condition is found, and this defect is due to an extension of the inflammatory process along the course of the Eustachian tube, and further the condition is not thought of, save in connection with an acute or subacute naso-pharyngeal inflammation. Whereas in middle life and childhood you will find enlarged tonsils, adenoid vegetations at the vault of the pharynx or a more diffused form of hypertrophy of the mucous membrane, and this condition extending or continuing, secondary lesions of the labyrinth occur and destroy the healing power altogether.

The nasal passages being free from obstruction, the acts of breathing, yawning and respiration aid in properly ventilating the middle-ear, restoring the equilibrium of the internal air and external atmospheric pressure which is essential to perfect hearing; but when obstruction does occur, the acts just mentioned produce a rarifaction of the air in the middle-ear, and its effects are similar to that produced by obstructions of the tube, and it is important that this be observed and operative procedures instituted for its relief.

There is another condition whose factor plays an important rôle in naso-pharyngeal inflammation, barring those conditions which primarily had their origin in a proliferative inflammatory condition, producing a great increase in the connective element, and finally ending in contraction and hardening of the same, thus causing sclerosis, and that is the use of tobacco.

The nares and naso-pharynx, on inspection, are free from obstructive lesions; yet the membrane is found to be passively inflamed with isolated points of a scarlet color, and with that exists the history of excessive smoking and the expulsion of the smoke through the nares and the possible use of stimulants; to this is added the constitutional effects of the tobacco poison, causing a disturbance of the vaso-motor centers, and thus rendering them more susceptible by this addition to the disturbing element, and from this effects are produced upon the ear similar to amblyopia and amaurosis.

It is therefore our duty to seek further in the causation of catarrh of the middle-ear, and to regard it as a factor or a local expression of a remote disease which is dependent upon an already existing naso-pharyngeal irritant, inflammation or obstructive lesion, and whose relief is dependent upon the conjoined medication of the naso-pharynx and middle-ear.

REPORT OF CASES.

CASE I. Mrs. B., aged thirty-five years, consulted me September, 1885, for deafness, saying that it had gradually developed for four or five years, and at times she could hear fairly well until the present time; that she was now unable to hear the watch tick on contact with the ear, and was greatly annoyed by roaring sounds in the ear. There was also difficulty in breathing, she being compelled to breathe almost entirely through the mouth. The throat would become dry, and at night she suffered from attacks of coughing, and in the morning suffered from a dull, heavy headache. On examination of the nares, I found partial stenosis of the left side with almost complete stenosis of the right side, being able to pass a very small probe along the floor of the nose to the pharynx. This mass of tissue filled the nares from the lower part of the inferior meatus to the superior; while, on the left side, the upper part of the inferior and middle meati were involved. This mass was fibroid in character, very dense and firm.

The membrana tympani was retracted and opaque, without any inflammatory deposits upon the same. I cocainized the right naris and passed a long narrow knife through the center and found it extended to the posterior portion of the middle meatus, when, on using the larger knives, I removed the mass completely, and, after several months, I did the same to the right side. When the resultant inflammatory condition subsided, I treated the ear by the Politzer method, and the hearing was restored. From hearing the watch ticking on contact she could hear it at twenty inches, with subsidence of the tinnitus aurium.

CASE II. Dr. C. consulted me two years ago, suffering from a violent tinnitus aurium and partial deafness. When, on inspection, I found naso-pharyngeal inflammation, no diffuse, but points of isolation, particularly in the pharynx. The membrana tympani showed nothing abnormal; watch heard four inches.

The doctor suggested that possibly it was due to frequent smoking, as on a previous occasion this had occurred after visiting the clubs and indulging in frequent smoking. To ascertain if this was the exact cause, I advised the local treatment of an alkaline solution to the naso-pharynx and omitted medication to the ear. This was done, and in a short time the hearing returned to its normal condition, and since then, whenever an excess in smoking occurs, the above symptoms are reproduced, which subside after the disuse of tobacco.

DR. MACKENZIE says that a solution of two parts of tannic acid and one part of gallic acid will stop any hemorrhage after excision of the tonsils.

NASAL REFLEXES.[1]

By A. B. THRASHER, A.M., M.D.,
CINCINNATI, O.

THE multiplicity of symptoms attributed by the modern rhinologist to nasal reflexes has caused not a little opprobrium to fall to the lot of the specialist.

Among the affections attributable to intra-nasal lesions are: Asthma, hay-fever, cough, spasm of glottis, gastralgia, dyspepsia, tumefaction and redness of skin of nose, œdema of conjunctiva, conjunctivitis, photophobia, epiphora, asthenopia, glaucoma, scotoma, salivation, cardiac palpitation; disorders of smell, taste, hearing and sight; huskiness of voice and aphonia; exophthalmic goitre, rheumatic pains, vertigo, choræ, epilepsy, melancholia, agoraphobia, aprosexia, neurasthenia, migraine, cephalalgia, neuralgias, nocturnal eneuresis; many uterine disorders, affections of the genito-urinary mucous membrane, etc., etc.

Many of the affections are not true reflexes, but are caused by blood pressure, or by extension of inflammation by continuity of tissue, or in some other way not reflex. The specialist should carefully examine the nose, but he should also be a general physician, and search the entire system for the often obscure *causus morbi.*

Dr. Thrasher reported two cases of reflex salivation, due to intra-nasal disease.

He thought that the cause of the nasal reflex was twofold:

Primarily, a diseased condition of the respiratory tract of the nose.

Secondarily, an abnormal irritability of the central nervous ganglia. This affection of the central nervous system might be caused by repeated irritation of the intra-nasal tissues, or it might be due to some extra-nasal irritation. It was more apt to be manifest in individuals of a nervous dyscrasia.

The condition of vaso-motor paresis, very different from active inflammation, is generally present, although it may be masked by acute inflammation.

The immediate exciting cause of the reflex may be a mechanical, chemical, or thermal irritant.

There is at times some difficulty in making the diagnosis, as the severity of the reflex is not in proportion to the amount of nasal disease. Neither does it follow that when one of the above symptoms is present, along with well marked intra-nasal disease, that the latter is due to the former. Sometimes the local application of cocaine will abolish the reflex; or, again, it may be excited by the irritation of a nasal probe; but the means are not always to be relied on.

As a rule, constitutional as well as local treatment must be instituted.

In these reflex disturbances it becomes apparent that the specialist should be broad in his ideas—not viewing the whole world through his nasal speculum, or not expecting to see the cause of all bodily ailments reflected in his rhinoscope.

THE "Red Cross of Italy" adds steadily to its efficiency. Its Genoese section was called out for mobilization exercise on the 12th ult. They marched to Cusella, and thence along the Alpine road, threading the pass between Giano and Ponte-de-cimo, and returning by rail.

[1] Abstract of paper read before the American Rhinological Association, October, 1890.

NOTE ON THE USE OF TINCTURE OF CAPSICUM AS A COUNTER-IRRITANT.

By P. S. DONNELLAN.

IN *The Lancet* of May 17 Sir James Sawyer, drew attention to the excellent results obtained by the use of tincture of capsicum as a counter-irritant. In the same journal of May 31 Dr. Buck, of London, endorsed the observations of Sir James Sawyer, and stated that he had used the drug extensively with the same object during the past twenty years, with unvarying success. Since the publication of the above notes I have had several opportunities of testing the efficacy of tincture of capsicum in the relief of all forms of superficial pain, but more especially in cases of sciatica, neuralgia, pleurodynia, and muscular rheumatism. In my hands it has never failed to give relief, and on more than one occasion the effect was described as magical.

The mode of application is as follows: A piece of canton flannel or lint is freely sprinkled with tincture of capsicum (U. S. P.), applied over the seat of pain and covered with oiled silk. The patient almost immediately experiences a slight burning sensation, followed by a speedy diminution of the pain. The advantages of the external use of tincture of capsicum over other counter-irritants are:

It is certain and rapid in its action.

It does not produce ossication, as is the case with cantharides, or the prolonged application of mustard and iodine.

Its action is uniform, and can be kept up for an indefinite period.

1122 WALNUT STREET, PHILADELPHIA.

Society Notes.

PROCEEDINGS OF THE PHILADELPHIA ELECTRO-THERAPEUTIC SOCIETY.

THE Society met at 2005 Arch street, Thursday, November 9, 1890. President Massey in the chair.

The minutes of the last meeting were read and adopted.

At the previous meeting Dr. O. P. Willits was appointed to read a paper to-night, but being unable to be present, the paper was sent to the Secretary, and read by him, its title being

THE ELECTRICAL TREATMENT OF INFANTILE PALSY.

After quoting the opinions of Erb, Roth, Gowers, and others, the author gave brief histories of a series of cases treated at the Orthœpedic Hospital by electricity, and from the results drew the following conclusions: That while in some stages of the disease Franklinic and Faradic applications might be useful, galvanism was always of advantage, even where no apparent progress was being made, for in many, if not all cases, a retrogression was prevented, and this in itself was sufficient to justify its use. There are few cases that will fail to improve, to some extent at least, and galvanism is, probably, the best single remedy that we have for infantile palsy.

Dscussion.—DR. MASSEY took the floor, and said that the attention of the profession at large should be called to the close relation existing between summer diarrhœa in children and the lesion under consideration, the paralysis manifesting itself either during or after an attack of diarrhœa.

As to treatment he thought that the interrupted galvanic current was too powerful for such cases. The benefit was from the stimulation of nutrition, and in his opinion galvano-massage was the better form of application. He used strong currents, going from ten up to thirty ma. with children, and as high as fifty ma. upon adults, the negative being the active pole.

While the electrical treatment of poleo-myelitis was tiresome, and sometimes apparently fruitless, yet it was the only method of any value, and once commenced should be continued for at least a year.

DR. TAYLOR called attention to the conditions in this disease. On all cases there is an inflammation in the spinal cord, acute at first, finally becoming chronic, and which should receive appropriate treatment. On the first, or acute, stage he suggested wetting the active electrode, in this case the positive, with a solution of chloride of ammonium, adding that he thought the same application should be made to all acute inflammations treated by electricity.

DR. WALLING stated that while galvanism was the main stay in the lesion under consideration, yet Franklinic electricity was of undoubted benefit if properly used. His method of treatment, in some cases, was to use galvano-massage twice each week and the Franklinic spark once a week. Under both treatments the parts are well reddened, and nutrition stimulated.

DR. TAYLOR stated that when the blood supply was deficient atrophy resulted; but as long as the proper distribution of the blood was maintained, there was no atrophy.

DR. WALLING said that it was with this end in view, that is, to maintain this supply, that he used the Franklinic spark, as it was a powerful stimulant, not only to the sanguineous, but to the lymphatic circulation as well.

DR. MASSEY thought that the good results attributed by Dr. Taylor to the use of the chloride of ammonium were to be referred to the increased current, rather than to any especial virtue in the ammonium salt, and that the same lessening of resistance was obtained by the use of any other salt.

DR. TAYLOR answered that he invariably used the chloride of ammonium as a dressing in inflammatory conditions, and had derived great benefit from such applications, and regarded it as a very valuable antiphogistic. If it was so good, when used by itself, would it not be better when applied with electricity?

DR. KAHN thought that large electrodes should be used, and the treatment be long continued.

DR. WALLING exhibited his bandage, which consists of an ordinary muslin bandage covered with tinfoil, and stitched so as to render it firm; the object of the inner, or muslin lining being to give it strength.

It was to be used as follows: An ordinary bandage, or towel, after being well wetted, was wrapped around the limb, or inflammed joint, and Walling's bandage then applied over the whole, the proper pole of the battery attached, the other pole being *in situ*, when the current could be gradually turned on. He had had great success in synovitis and other joint affections by the use of this bandage in making electrical applications.

Adjourned. WM. H. WALLING, M.D.,
Secretary.

THE outbreak of typhoid fever at Arundel has assumed a serious aspect. The cases of the disease are stated to be very numerous, and several deaths are reported.

The Polyclinic.

MONTI employs the following formula in whooping-cough:

℞.—Quininæ, ... gr. vi–gr. ix.
Sodii bicarb.,
Sacchari alb., ... ää gr. xx.—M.
Divide in chartulas No. x.
S. One powder every two hours.

—Jahrb. f. Kinderheilk, *Archives of Gyn. and Pæd.*

IRON, GLYCERINE, AND CHLORATE OF POTASSIUM MIXTURE.—

℞.—Tincture of chloride of iron, . . . 30 mins.
Chlorate of potassium, ... 1 dr.
Glycerine, ... ½ oz.
Water, ... sufficient to make 4 "
Dose for adults, a teaspoonful every two hours; children, 20 drops to half a teaspoonful, according to their age.

TREATMENT OF OZENA.—1. In order to disembarrass the nasal passages of the scab that they inclose, make first morning and evening a nasal irrigation with a liter of tepid water, in which is dissolved one or two teaspoonfuls of the following powder:

Bicarbonate of soda, ... 50 grammes.
Borate of soda, ... 30 "
Chlorate of potash, ... 20 "
F. s. a.—

It is necessary to take care to hold horizontally the canula of the English syringe in bending the head lightly forward and without taking breath while pressing upon the injector.

2. Then a second injection is made with the mixture of the two following solutions which are prepared separately: (*a*) In a glass filled with hot water put a teaspoonful of the powder of boric acid. (*b*) In a second glass, containing tepid water, pour a dessertspoonful of the solution: Naphthol α or β, 5 grammes; alcohol, 10 grammes; boiling water, 1 liter.

3. Gargle with the quantity of a Madeira glassful of the following solution:

Borate of soda, ... 10 grammes.
Distilled water, ... 250 "
Glycerine, ... 30 "
Peppermint water, ... 30 "

It is necessary to throw the head backward and to make some movement of deglutition, then to bring the head forward, in making an effort of expiration, the mouth being shut in order to permit the liquid to pass out by the nasal passages.

4. Clean well the pharynx and the nasal passages with a thin stick covered with cotton. Paint consecutively all the parts with a stick covered with wadding, dipped in the following solution:

Naphthol-β pulverized, ... 5 grammes.
Powdered camphor, ... 10 "

5. Triturate to liquefaction and add vaseline liquid, ten to fifty grammes, f. s. a. sol. Every eight or fifteen days cleanse alternately with the following solution:

A cresylic, ... 1 gramme.
Glycerine, ... 50 "
F. s. a.—

(We reject the employment of creolin and of cresyl in injections or atomizations.)

6. In cases where the secretion is abundant, and when the patient is not able to be regularly attended by the physician, it is necessary to add to the irrigations some atomizations with the solution of diluted naphthol, which alternates with a solution of creosote at 1-300 or with some balsamic solutions (pitch or tar, benzoin, balsam of tolu, turpentine) employed alone or united.—Baratoux, *Am. Pract. and News.*

DR. KOCH'S REMEDY FOR TUBERCULOSIS.

THE story of Dr. Koch's discovery of a cure for tuberculosis, although dating only a few weeks back, is an old one to the most of our readers. Yet, we feel confident that even the most unimpassioned man of science must surely be filled with intense interest, if not enthusiasm, as he peruses the story of the discovery and watches the development of the results. Surely we stand on the brink of a new epoch in medicine. The exhibition of untiring energy, indefatigable labor, and undeniable genius which is shown by the work of the Berlin bacteriologist, compels us to render homage, and has called forth world-wide admiration. Robert Koch has done well—done well in his labors, and done well in his manner of presenting them to the profession and public.

True, the lay press has garbled accounts of his discovery, misstated it, given it colorings that never came from its author, and, as it usually does, has done both Koch and the discovery harm. Every precaution has been used by the investigator to prevent any misconception or misstatement, but in vain.

It has been largely for this reason that THE TIMES AND REGISTER refrained from joining the throng of medical journals, and has kept its ever-indulgent readers somewhat in suspense. We have, however, been keenly alive to their interests as ever, and therefore concluded "to look well before we jumped." Dr. Koch has now published, in the *Berliner Medicinische Wochenschrift*, a preliminary paper upon his discovery.

No doubt, says the *Lancet*, this publication has been, in a sense, forced on him by the extraordinary anxiety manifested on all sides to learn something tangible concerning a remedy about which the greatest possible expectation has been raised. From one point of view, therefore, this early publication is to be deprecated, since it does not contain any records of cases, or any account of the lines pursued by the discoverer in the production of the remedy, and no exception can be taken to a postponement of final judgment until all these facts are before the profession. Nevertheless, there are few men more worthy of confidence than Prof. Koch, whose whole record is that of the patient, earnest seeker after truth, and who has already done so much to widen our conceptions of disease. That this is the general opinion is shown by the reception given to the first intimations by him that he was within reach of succeeding in his search for an antidote to the tubercular virus. Such a statement from many another source would have been received with more than incredulity; but this announcement, when made at the International Medical Congress, was welcomed as "glad tidings of great joy," for it was generally felt that Robert Koch was a man who seldom made a statement which he could not justify, and one who, in this particular instance, must have felt the tremendous issues depending on his utterances. This comparative absence of scepticism amongst a profession who have good reason for being sceptical of alleged "specific" cures, is further explained by the conviction of the truth of the doctrine that tuberculosis is owing to the invasion of the body by a parasitic bacillus, of which Prof. Koch was himself the discoverer, and with the life-history of which he is very familiar. If, indeed, he has succeeded in showing how this insidious foe of mankind can be held in check, he has crowned his first achievement by a still greater discovery, and will have earned undying fame.

Impartiality is always a characteristic of this journal; however, in the presence of the remarkable degree of public interest and professional approval, this is, indeed, difficult.

Berlin has been inundated, not only by an overwhelming tide of consumptives, but also by representatives of the profession from all parts of the world. Already warning voices are being raised in Vienna and Berlin in the attempt to stem the tide of misconception which is rolling in a veritable flood of consumptives to the Prussian capital. To all such, and to all members of the profession who may be called upon to advise for or against the immediate trial of the new remedy, we would counsel a policy of caution. At the present time the profession has only one official guide before it, namely, Koch's article in the *Berliner Medicinische Wochenschrift;* and, therefore, with the above statement of our position and feelings, we will proceed to review this paper for our readers.

The first mention made by Koch, of this remedy, was in an address delivered before the International Medical Congress, in which he spoke of a remedy which conferred upon animals experimented with an immunity against inoculation with the tubercle bacillus. The paper under discussion deals with similar investigations carried out on human subjects.

It was originally Dr. Koch's intention to complete the research, and especially to gain sufficient experience regarding this application of the remedy in practice, and its production on a large scale, before publishing anything on the subject. But, as we have said, in spite of all precautions, too many accounts have reached the public, and that in an exaggerated and distorted form, so that the publication of the preliminary article seemed imperative, in order to prevent all false impressions.

The investigations have been carried on, under

Professor Koch's directions, by Dr. A. Libbertz and Staff-physician Dr. E. Pfuhl, and are still in progress. Patients were placed at Dr. Koch's disposal by the leading physicians of Berlin.

As regards the origin and the preparation of this remedy, Dr. Koch claims to be unable to make any statements, for the reason that his research is not yet concluded. He reserves this for a future communication.

The remedy is a brownish transparent liquid, which does not require special care to prevent decomposition. For use the fluid must be more or less diluted, and these dilutions are liable to decomposition if prepared with distilled water; bacterial growths soon develop in them, they become turbid and are then unfit for use. To prevent this, the diluted liquid must be sterilized by heat, and preserved under a cotton-wool stopper; or, better still, prepared with a one-half per cent. solution of carbolic acid. It would seem, however, that the effect is weakened both by frequent heating and by mixture with carbolic acid solution, and therefore Dr. Koch always made use of freshly prepared solutions. Introduced into the stomach, the remedy has no effect; in order to obtain reliable effect it must be injected subcutaneously. For this purpose Dr. Koch has used exclusively the small syringe suggested by him for bacteriological work; it is furnished with a small rubber bulb, and has no piston. This syringe can be easily kept aseptic by absolute alcohol, and to this Koch attributes the fact that not a single abscess has been observed in the course of more than a thousand subcutaneous injections. The place chosen for the injection—after several trials in other places—was the skin of the back between the shoulder blades and the lumbar region, because here the injection led to the least local reaction—generally none at all—and was almost painless.

In the healthy subject the injection of the remedy produces, within three or four hours, a pain in the limbs, fatigue, inclination to cough, and difficulty in breathing, which speedily increases. During the fifteen hours an unusually violent attack of ague follows, which lasts for an hour. At the same time there is nausea vomiting and a considerable rise of temperature. The next day the temperature falls to normal, but the feeling of fatigue and pain in the limbs continues for a few days, and for exactly the same time the site of the injection remains painful and slightly red. These are Koch's personal experiences with the remedy injected into his own arm. We will pass over the description of the specification of the remedy on tubercular processes, and proceed to the more important question of the local and general reaction, the diagnostic value of the method, the curative effect of the remedy, the dose, and the application. In this, we have been greatly aided by the admirable translation of Dr. Koch's article in the *British Medical Journal's* supplement:

The specific action of the remedy in cases of lupus is less striking, but is perceptible to eye and touch, as are the local reactions in cases of tuberculosis of the glands, bones, joints, etc. In these cases swelling, increased sensibility, and redness of the superficial parts are observed. The reaction of the internal organs, especially of the lungs, is not at once apparent, unless the increased cough and expectoration of consumptive patients after the first injections be considered as pointing to a local reaction. In these cases the general reaction is dominant; nevertheless, Dr. Koch feels justified in assuming that here, too, changes take place similar to those seen in lupus cases.

The symptoms of reaction above described occurred without exception in all cases where a tuberculous process was present in the organism, after a dose of 0.01 cubic centimeter, and the remedy will, therefore, in the future form an indispensible *aid* to diagnosis. By its aid we shall be able to diagnose doubtful cases of phthisis; for instance, cases in which it is impossible to obtain certainty as to the nature of the disease by the discovery of bacilli or elastic fibres in the sputum, or by physical examination. Affections of the glands, latent tuberculosis of bone, doubtful cases of tuberculosis of the skin, and such like cases, will be easily and with certainty recognized. In cases of tuberculosis of the lungs or joints which have become apparently cured we shall be able to make sure whether the disease has really finished its course, and whether there be not still some diseased spots from which it might again arise as a flame from a spark hidden by ashes.

Of much greater importance, however, than its diagnostic use is the therapeutic effect of the remedy. In the description of the changes which a subcutaneous injection of the remedy produces in portions of skin changed by lupus it is mentioned that after the subsidence of the swelling and decrease of redness the lupus tissue does not return to its original condition, but that it is destroyed to a greater or less extent, and disappears. Observations show that in some parts this result is brought about by the diseased tissue becoming necrotic even after one sufficient injection, and at a later stage it is thrown off as a dead mass. In other parts a disappearance, or, as it were, a melting of the tissue, seems to occur, and in such cases the injection must be repeated to complete the cure.

In what way this process occurs cannot as yet be said with centainty, as the necessary histological investigations are not complete. But so much is certain that there is no question of a destruction of the tubercle bacilli in the tissues, but only that the tissue enclosing the tubercle bacilli is affected by the remedy. Beyond this there is, as is shown by the visible swelling and redness, considerable disturbances of the circulation, and, evidently in connection therewith, deeply seated changes in its nutrition which cause the tissue to die off more or less quickly and deeply, according to the extent of the action of the remedy.

To recapitulate, the remedy does not kill the tubercle bacilli, but the tuberculous tissue; and this gives us clearly and definitely the limit that bounds the action of the remedy. It can only influence living tuberculous tissue; it has no effect on dead tissue, as, for instance, necrotic cheesy masses, necrotic bones, etc., nor has it any effect on tissue made necrotic by the remedy itself. In such masses of dead tissue living tubercle bacilli may possibly still be present, and are either thrown off with the necrosed tissue or may possibly enter the neighboring still living tissue under certain circumstances. If the therapeutic activity of the remedy is to be rendered as fruitful as possible, this peculiarity in its mode of action must be carefully observed. In the first instance, the living tuberculous tissue must be caused to undergo necrosis, and then everything must be done to remove the dead tissue as soon as possible, as, for instance, by surgical interference. Where this is not possible, and the organism can only help itself in throwing off the tissue slowly, the endangered living tissue must be protected from fresh incursions of the parasites by continuous application of the remedy.

The fact that the remedy makes tuberculous tissue necrotic, and acts only on living tissue, helps to explain another peculiar characteristic thereof, namely, that it can be given in rapidly increasing doses. At first sight, this phenomenon would seem to point to the establishment of tolerance, but since it is found that the dose can, in the course of about three weeks, be increased to 500 times the original amount, tolerance can no longer be accepted as an explanation, as we know

of nothing analogous to such a rapid and complete adaptation to an extremely active remedy. The phenomenon must rather be explained in this way, that in the beginning of the treatment there is a good deal of tuberculous living tissue, and that consequently a small amount of the active principles suffice to cause a strong reaction; but by each injection a certain amount of the tissue capable of reaction disappears, and then comparatively larger doses are necessary to produce the same amount of reaction as before. Within certain limits a certain degree of habituation may be perceived.

As soon as the tuberculous patient has been treated with increasing doses for so long that the point is reached when his reaction is as feeble as that of a non-tuberculous patient, then it may be assumed that all tuberculous tissue is destroyed. And then the treatment will only have to be continued by slowly-increasing doses and with interruptions, in order that the patient may be protected from fresh infection while bacilli are still present in the organism.

Whether this conception, and the inferences that follow from it, be correct, the future must show. They were conclusive, according to Dr. Koch, in determining the mode of treatment by the remedy, which, in his investigations, took the following form:

To begin with, the simplest case, lupus; in nearly every one of these cases the full dose of 0.01 cubic centimeter was injected from the first. The reaction was then allowed to come to an end entirely, and then, after a week or two, again 0.01 cubic centimeter was injected, continuing in the same way until the reaction became weaker and weaker, and then ceased. In two cases of facial lupus, the lupus spots were thus brought to complete cicatrization by three or four injections; the other lupus cases improved in proportion to the duration of treatment. All these patients had been sufferers for many years, having been previously treated unsuccessfully by various therapeutic methods.

Glandular, bone, and joint tuberculosis was similarly treated, large doses at long intervals being made use of; the result was the same as in the lupus cases—a speedy cure in recent and slight cases, slow improvement in severe cases.

Circumstances were somewhat different in phthisical patients, who constituted the largest number of Koch's patients. Patients with decided pulmonary tuberculosis are much more sensitive to the remedy than those with surgical tuberculous affections. He was obliged to lower the dose for the phthisical patients, and found that they almost all reacted strongly to 0.002 cubic centimeter, and even to 0.001 cubic centimeter. From this first small dose it became possible to rise more or less quickly to the same amount as is well borne by other patients.

The course was generally as follows: An injection of 0.001 cubic centimeter was first given to the phthisical patient; on this a rise of temperature followed, the same dose being repeated once a day until no reaction could be observed. The dose was then raised to 0.02 cubic centimeter until this was borne without reaction; and so on, rising by 0.001, or at most 0.002, to 0.01 cubic centimeter and more. This mild course seemed imperative in cases where there was great debility. By this mode of treatment the patient could be brought to bear large doses of the remedy with scarcely a rise of temperature. But patients of greater strength were treated from the first, partly with larger doses, partly with rapidly-repeated doses. Here it seemed that the beneficial results were more quickly obtained.

The action of the remedy in cases of phthisis generally showed itself as follows: Cough and expectoration generally increased a little after the first injection, then grew less and less, and in the most favorable cases entirely disappeared; the expectoration also lost its purulent character, and became mucous.

As a rule, the number of bacilli only decreased when the expectoration began to present a mucose appearance; they then from time to time disappeared entirely, but were again observed occasionally until expectoration ceased completely. Simultaneously the night sweats ceased, the patients' appearance improved, and they increased in weight. Within four to six weeks, patients under treatment for the first stage of phthisis were all free from every symptom of disease, and might be pronounced cured. Patients with cavities not yet too highly developed improved considerably, and were almost cured; only in those whose lungs contained many large cavities could no improvement be proved objectively, though even in these cases the expectoration decreased, and the subjective condition improved.

In part, this may be assumed for other cases, when not too far advanced; but patients with large cavities, who almost all suffer from complications caused, for instance, by the incursion of other pus-forming micro-organisms into the cavities, or by incurable pathological changes in other organs, will probably only obtain lasting benefit from the remedy in exceptional cases. Even such patients, however, were benefited for a time. This seems to prove that in their cases, too, the original tuberculous disease is influenced by the remedy in ths same manner as in the other cases, but that we are unable to remove the necrotic masses of tissue with the secondary suppuration processes.

The thought suggests itself involuntarily that relief might possibly be brought to many of these severely afflicted patients by a combination of this new therapeutic method with surgical operations (such as the operation for empyema) or with other curative methods. And here Dr. Koch would earnestly warn people against a conventional and indiscriminate application of the remedy in all cases of tuberculosis. The treatment will probably be quite simple in cases where the beginning of phthisis and simple surgical cases are concerned; but in all other forms of tuberculosis medical art must have full sway by careful individualization, and making use of all other auxiliary methods to assist the action of the remedy. The most important point to be observed in the new treatment is its early application. The proper subjects for treatment are patients in the initial stage of phthisis, for in them the curative action can be most fully shown, and for this reason, too, it cannot be too seriously pointed out that practitioners must in future be more than ever alive to the importance of diagnosing phthisis in as early a stage as possible. Up to the present, the proof of tubercle bacilli in the sputum was considered more as an interesting point of secondary importance, which, though it made diagnosis more certain, could not help the patient in any way, and which, in consequence, was often neglected.

In future this must be changed. A doctor who shall neglect to diagnose phthisis in its earliest stage by all methods at his command, especially by examining the sputum, will be guilty of the most serious neglect of his patient, whose life may depend on this diagnosis and the specific treatment at once applied in consequence thereof. In doubtful cases medical practitioners must make sure of the presence or absence of tuberculosis, and then only the new therapeutic method will become a blessing to suffering humanity when all cases of tuberculosis are treated in their earliest stage, and we no longer meet with neglected serious cases, forming an inextinguishable source of fresch infections. Finally, Dr. Koch says that he has purposely omitted statistical accounts and descriptions of individual cases, because the medical men who furnished him with patients for investigations have themselves decided to publish the description of their cases, and because he wishes to be as objective as possible, leaving to them all that is purely personal.

Such is briefly a description of Dr. Koch's method for the cure of tuberculous diseases. We have endeavored to preserve the author's simplicity of diction and direct style. As soon as further reports are made, our readers shall profit by them, and feel sure that all of them will add to ours, their hearty appreciation of Robert Koch's labors, zeal, and—we trust—permanent results.

DR. CHARLES T. BEAN died at Chelsea, Mass., of pneumonia. He weighed 504 pounds.

Annotations.

THE TREATMENT OF BURNS.

BARDELEBEN treats burns after the following plan, which we quote from the *Hospital Gazette*. The injured part is first thoroughly washed with carbolic acid solution from 2½ to 3 per cent., or with a solution of salicylic acid about 3 in 1,000. All the bullæ are then punctured and the serum allowed to escape, after which the whole part is thoroughly dusted with finely powdered nitrate of bismuth, and a thick layer of cotton wool applied. The latter is changed whenever it is impregnated with the discharges from the wound. If the burn is a very extensive one, the powdered bismuth may be set aside, and a bismuth ointment used instead. The author affirms that with this dressing cicatrization proceeds rapidly, and there is less discomfort than when any other dressing is employed. Despite the large quantities of bismuth that have been applied no toxic symptoms have been noted in consequence of its use.

EMPYEMA.

DR. HENRY T. BEWLEY thus sums up his conclusions on The Pathology of Empyema, in an article on that subject in the *Dublin Journal of Medical Science*:

1. Empyema is always caused by micro-organisms.
2. These are of different species, there being no one specific variety.
3. In some cases ordinary pus-producing and putrefactive bacteria get into the pleural cavity through some opening in the chest-wall or lung.
4. Some cases are associated with croupous pneumonia, and are caused by the pneumococcus.
5. Some cases are due to the action of the tubercle bacillus.
6. In some cases pus-producing micrococci, which have in some way got into the blood, but are not, if unassisted, able to develop in the body, find in an inflamed pleura or serous effusion a locality suitable for their development, and under their influence a serous effusion becomes purulent.
7. Some cases are pyæmic.

AMERICAN MEDICAL EDUCATION.

LOOKING at the system of medical education in America as it has prevailed for many years, we observe a peculiar and unsatisfactory state of affairs growing out of the following conditions:

This is denominated a free country.

There is entire absence of national authority or control in matters of education.

Each State regulates its educational institutions as it may see fit, or rather, we might say, leaves them to manage themselves.

Many of these institutions are to all intents and purposes, private corporations, conducted in the interest of private individuals, untrammeled to a great extent by legal enactments, and controlled in their conduct only, by a poorly educated and unenlightened public opinion.

So speaks Dr. R. B. Maury in a lecture delivered at the opening of the Memphis Hospital Medical College. If the worthy doctor is ever able to secure for the control of medical, or any other educational institutions, a cultivated and enlightened, instead of "a poorly educated and unenlightened public opinion," he will secure what even the most sanguine of us shrink from hoping for.

SALIVA FOR WARTS.

A GENTLEMAN, aged about seventy-three years, had a number of warts upon his hands, some of them being quite large and unsightly. He was advised to wet the warts with saliva many times daily; in fact, whenever he thought of it. He did so, and in a few weeks the warts had disappeared.

As warts are now generally regarded as due to local tuberculosis, this case suggests the possibility that Koch may have found his asserted remedy among the digestive fluids of the human body. Some years ago, Drs. Randolph and Dixon performed some experiments with trypsin, which showed that this substance, when applied in milk to the human skin, digested the latter, causing troublesome ulceration.

Every report from Berlin, however, renders it more probable that our first surmise was correct, and that the new remedy is a sterilized culture fluid of the bacillus tuberculosis.

IN FAVOR OF CÆSAREAN SECTION.

PROFESSOR ARTHUR V. MASON, in an account of A Case of Successful Cæsarean Section, reported in the *Dublin Journal of Medical Science*, gives the following reasons in favor of Cæsarean section, as against the operation of Porro:

On looking up the most recent authorities I found that they were in favor of Cæsarean section, and against the operation of Porro, except when there was a positive indication for the removal of the uterus present. These are chiefly—

1. When the uterus is the seat of any disease, such as myoma, which, if left behind, might soon require removal.
2. When the woman is suffering from any disease, such as osteo-malacia, the cure of which might be seriously interfered with or even prevented by a subsequent pregnancy.
3. When the patient has already been so long in labor that it is probable that the discharge is beginning to decompose, or when she has been examined by persons who may easily have infected her, or where she shows evident signs of infection having taken place. As none of these conditions were present, I determined to perform Cæsarean section.

TREATMENT OF ANEURISMS.

WILLIAM MACEWEN in a paper read before the Midland Medical Society, of Glasgow, and published in the *Lancet*, says: The attempts to produce coagulation in aneurismal sacs by the introduction of foreign bodies into their interior, although occasionally successful, have failed as a rule, especially on aneurisms at the root of the neck, or where the circulation could not be controlled on the proximal side of the sac. Those who have endeavored to produce red thrombi for the purpose of occluding an aneurism under these circumstances have omitted one of the most important elements, without which success cannot be secured—namely, placing the blood in the sac in a state of rest. In intra-thoracic aneurisms and those at the root of the neck the arrest of the blood-stream is an inherent impossibility, except by occlusion of the sac; and, therefore, in them this mode of treatment is not applicable. When red thrombi are formed, in the presence of a vigorous blood-stream, they are more liable to disintegration and absorption than to organization.

It is in this way the red thrombus formed on the positive electrode by galvanism is so often of no benefit. But why are there some successes, complete or partial, and how do these arise? It is due to these successful stray cases that a half-hearted belief in this line of treatment still lingers. In the majority of such subjected to pathological examination at various periods subsequently to the complete or partial cure, the sac has been found to contain white thrombi, which, it is assumed, resulted from organization of the red thrombi. While not doubting that red thrombi may have organized tissue substituted for them, I believe that in many such the white thrombi have originally formed as such, and were caused not intentionally by the operation, nor from any effect upon the blood-stream, but by accidental circumstances quite apart. Thus, for instance, in certain aortic aneurisms treated by galvano-puncture, white thrombi have been noticed developed at the points punctured by the needles. These were attributed to the galvanism, whereas they were due to the damaged vessel wall setting up a reparative inflammatory process. This interpretation of the phenomenon receives support from the fact that white thrombi may be produced by penetration of the vessel wall without galvanism.

SULFONAL.

I THINK to get the best effect from sulfonal, it should be given in a hot drink about an hour before we wish the patient to go to sleep. I had a case not long since, that was suffering from an attack of melancholia. She had been an inmate of an insane asylum some three or four years ago. At the time I first saw her she was extremely nervous, had not slept any for several nights, and said she was very sure there was nothing in the world that could put her to sleep. The first night I gave her fifteen grains of sulfonal; she slept about four hours. The second night I gave her twenty grains, and she slept for ten hours, and was greatly refreshed and much less nervous. She had no unpleasant after-effects and continued to take a powder every other night for four nights. At the end of that time she could sleep without taking a hypnotic.

—Wright, *Journal of Materia Medica.*

BABY FARMING IN POLAND.

SOMETIME ago the *Lancet* directed attention to the systematic practice of baby farming as recently carried on in Poland, whence, with Warsaw as its center, it spread over the whole of Russia. Later intelligence has revealed the details of methodical cunning and cruelty which have enabled a band of miscreants charged with two hundred child murders to escape detection till within a very recent period. Four women and two men are said to have lived by this horrible business. Three of the former were related; of the men one was a gravedigger, the other a coffin maker. Infants entrusted to the women died in due course, of starvation, and were buried periodically in batches of six together in one adult coffin. The confederacy was in fact an automatic trap for infant life of simple and precise construction, and, in the evident absence of effectual registration, very successful in its use. It seems remarkable that in a country where police inspection is carried to an extreme this multiplied and aggravated crime should have passed so long undiscovered. Official acuteness, it is clear, has been completely outwitted, and it is only reasonable to expect that the authorities will now use every means to expose the causes of so great a failure and to prevent its recurrence. We have spoken of registration, and it would certainly seem that as regards this matter, a stricter process is very desirable, both as regards the nurses and the children. Not the least remarkable feature about these disclosures, however, is the leniency of the sentences inflicted on the perpetrators of so many crimes. The chief offender, it is said, will bear the light burden of three years' imprisonment, the others less in proportion.

SLAUGHTER HOUSES AND THEIR ABUSE.

DR. R. HARVEY REED, in a report before the Richland County [Ill.] Humane Society on the subject of slaughter shops, which he investigated at the request of the society, says, among other telling things:

"Who knows how many cholerated chickens and turkeys have found their way into our markets and been eaten by our people? The common 'pudding meat' of our shops has an interesting history, surrounded with fragrance and tainted with romance. This delicate luxury is the child of the shop-soured scraps that have become unsalable, which are cooked up with, and not infrequently, the calves and sheep heads (the two latter with the brains and eyes also) until the bones can be shook out of them, when they are picked out and the meat is ground up and seasoned highly so as to cover any tainted flavor it may have, and is then stuffed in skins, when it is ready for sale; and in this way an unpalatable, unmarketable batch of meat is made salable. Bologna sausage may be said to be just a grade above the former, but, likewise, is composed of shop-soured meat, mixed with 'blue meat,' *i. e.*, old cows and the like that are too poor and tough to place on the market in any other shape.

"When an accumulation of this is gathered up, it is not infrequently sent to a foundry on Fourth street, where it is ground by steam in an old, dirty, fly-covered cutting box, all gummed up with dried blood, fibrin, and meat juices, whose fragrance is enough to entice the buzzards for miles around, but which is little better than some of the meat that is sent there to be ground. After this, the meat pulp is highly seasoned; a little smoked bacon is sometimes cut up with it to give it a palatable flavor, when the whole mass is thoroughly mixed and stuffed in skins, smoked a little, and placed on the market.

. . . . . .

"You would all 'gag' at the idea of eating dog meat, but will you tell me how much better in point of cleanliness and purity a hog is which is fattened on the poorest and foulest class of flesh imaginable, than the carnivora, whose nature it is to live on meat. Is it any wonder Germany has excluded the American hog from their markets? We are not here to condemn the hog that is fattened on corn and fares sumptuously on pure water every day; but the hog that quenches his thirst with blood, and is fattened on spoiled meat and intestines, is not fit for the use of man as an article of diet, in the humble opinion of the writer.

. . . . . .

"The building should be so constructed as to be always kept in a perfectly sanitary condition, as well as scrupulously clean. The floor should be made so it can be flushed, and kept perfectly clean, and the blood and offal all cleaned up every day and properly cared for, which should be done by cremating it, or by using it for a fertilizer, but not by feeding a pen of pigs in an adjoining inclosure to the slaughter house."

FRENCH NOTES.

BY A. E. ROUSSEL, M.D.

TREATMENT OF TUBERCULAR LARYNGITIS (Moure). —*In the inflammatory form* we will confine ourselves to a palliative and antiphlogistic treatment: counter-irritants (vesications or the actual cautery to the exterior of the larynx), inhalations or pulverizations soothing and antiseptic, occasionally emollient gargarisms, absolute rest of the organ.

If the epiglottis and the extra-laryngeal region are the seat of ulcerations, the gargarisms, or rather throat baths, judiciously employed, are useful.

The following gargarism is recommended as being both antiseptic and soothing:

℞.—Iodine (metallic), ...
Iodide of potassium, ... āā 5 grains.
Carbolic acid, ... ℥ss to gtts. 45.
Laudanum (Sydenham), ... ℥j.
Glycerine, ... ℥iv.

One teaspoonful of the above in a glassful of warmish water, to be used as a gargle three or four times a day.

If the patients object to the disagreeable taste, or if the results are not marked, we can use the following instead:

℞.—Carbolic acid or creasote, ... ℥ss to ℥j.
Bromide of potassium, ... grs. 45 to 75.
Laudanum (Sydenham), ... ℥j.
Glycerine, ... ℥iv.

One teaspoonful to a wineglassful of water.

From 7½ to 15 grs. of hydrochlorate of cocaine may be added to the above to render it more anesthetic.

Regarding local applications, they are not well supported as a rule, as they almost always irritate the larynx: if there is any trouble of deglutition, we may touch the ulcerated parts with a solution of cocaine or of morphine. If, for some reasons, local applications are counter indicated, the spray of the atomizer may be used for two or three minutes instead.

In the chronic form of laryngeal tuberculosis, if ulcerations exist, besides the pulverizations and inhalations, antiseptic and astringent of the first stage, which may also be employed here, the following solution may be used in the atomizer:

℞.—Chlorhydrate of cocaine, ... 4 to 5 grains.
Hydrate of chloral, ... 30 to 45 "
Bromide of potassium, ... 30 to 45 "
Glycerine (pure), ... 1½ ounces.
Distilled water, ... 6 ounces.

To be used three or four times a day, from three to five minutes.

In certain cases we will replace the cocaine by crystallized carbolic acid or by creasote.

In the third stage we make use of a solution such as the following:

℞.—Chlorhydrate of morphia, ... 4 to 10 grains.
" of cocaine, ... 6 to 15 "
Carbolic acid, ... 15 to 30 "
Glycerine (pure), ... 1 ounce.
Laurel water, ... 5 drachms.
Water, ... 9 to 16 ounces.

To be used in atomizer for two or three minutes; do not swallow.

We may replace the carbolic acid by 45 to 60 grs. of bromide of potassium, or hydrate of chloral, according to the indications.

To facilitate deglutition, we may touch the parts with the following solution five minutes before eating:

℞.—Chlorhydrate of morphia . . . . . 4 to 8 grains.
" of cocaine, ... 8 to 30 "
Glycerine (pure) . . . . . 7 ounces.

—*La Gazette Médicale.*

BILIARY FISTULA.—In a note on analysis of bile, Mr. Fairley says that from a biliary fistula the daily discharge was thirty ounces, much in excess of the quantity mentioned in the text-books. He states that the liquid was free from sulphates, while copper was always present. The gall-bladder fluid which mixed with the bile was possessed of considerable antiseptic properties.—*Amer. Practitioner and News.*

HAMAMELIS AND ALCOHOL IN THE TREATMENT OF NASAL POLYPI.—In an article on the treatment for the radical cure of polypi in the nose, Dr. E. Harrison Griffin recommends spraying the nose night and morning with sprays of witch hazel or of alcohol, at first diluted and gradually increased to full strength, for at least one year after thorough removal of the polypi with the wire snare. He reports a number of illustrative instances, in one of which he removed fully three hundred polypi at various sittings, and in another more than one hundred in the course of a week. Caustics and cautery after extirpation he finds to be almost invariably followed by renewed growths.

—*Medical Record.*

HABITUALLY MOIST FEET.—This is found most frequently in such persons as live well and take little exercise; also in young women of a somewhat nervous temperament, who indulge in the pernicious habit of frequent tea-drinking. Aside from its unpleasantness, the danger attending on wet feet is acknowledged, and it is also not rare for persons so affected to have their feet and legs icy cold for long periods of time. In the editor's experience, the best results of treatment have been obtained from the employment of foot-baths of a strong solution of extract of pinus canadensis (Kennedy's) every night, and the use of powdered boracic acid, or salicylic acid mixed with lycopodium, oxide of zinc, or other inert powder, constantly applied inside the stockings.

—Jamison, *Edinburgh Med Jour.*

Chronic Constipation.—At the meeting of the Berlin Medical Society Herr Flatau introduced a new method of treating cases of chronic constipation due to torpor of the colon. This consists in applying about three grammes of boric acid. In those cases in which the lower edge of the rectum protrudes through the anus, and when this remains visible after powerful contractions of levator ani and sphincters, the quantity of boric acid mentioned is either to be dusted on or rubbed on the mucous membrane in sight. In cases in which the mucous membrane is not visible it must be insufflated. It is important that the medical attendant should carry out the procedure himself, at any rate, at the commencement. The patient should then keep quiet for a time. In from an hour to three hours peristaltic action will be observed in the colon. He has never seen a failure from this method of treatment, nor had he seen a case where the patient got so accustomed to it that it ceased to be effective. On the contrary, if carried out systematically daily, permanent improvement in time takes place, and normal peristalsis is returned to. He had tried a number of other substances but none had the same useful effect.

—*Medical Press and Circular.*

At a recent meeting of the Edinburgh Medico-Chirurgical Society, reported in the *Medical Press and Circular*, Prof. Annandale read a paper on Wry-neck, its Varieties and their Treatment. He classified the varieties under four heads:

1. Simple wry-neck, contraction of one sterno-mastoid muscle, occurring in every degree, (1) congenitally, (2) from wounds of the muscle arising at childbirth or during operation, (3) from paralysis or wasting of one muscle from any cause, or (4) as a bad habit. The treatment of this form consisted in stimulation of the muscle by counter-irritation, massage, and galvanism, followed by the division of the tendon if the other methods were not sufficient.

2. Temporary spasmodic wry-neck, the result of spasmodic contraction of one sterno mastoid muscle. This was generally due to some local irritation, and the treatment of it was self-evident.

3. Permanent spasmodic wry-neck, a very distressing condition for the patient, coming on (1) as a result of the temporary form, (2) from general nervous conditions, and (3) from over-exertion of one of the sterno-mastoid muscles, as in the case of compositors and weavers. The treatment of this form was division of the spinal accessory nerve. Prof. Annandale here cited several cases in which he had performed this operation.

4. Complicated wry-neck, depending on disease of the vertebræ, cicatrices, tumors, or enlarged glands. In such cases the treatment was to get rid of the offending cause, and thereafter treat the wry-neck if necessary.

Paraldehyde as a Cause of Albuminuria.—In May, 1887, I was called to see Mrs. X., aged fifty-five. She had been considerably worried over family troubles, and, being unable to sleep, had two months previously consulted a homœopath in her neighborhood. He had prescribed elixir of paraldehyde. She had continued taking the drug in gradually increasing doses, and when I saw her had been taking from sixteen to eighteen ounces in the twenty-four hours. She was extremely morose, irritable, and apprehensive. The tongue was dry and coated with a brown fur, breath foul, lips cracked, and skin dry and parched. The teeth were discolored, and the hair had become very brittle. Her eyesight was very much affected; she was troubled with diplopia, and could not see the clock across the room. Her appetite was gone and she was much emaciated. The examination of the urine made on the second day showed one-fourth of one per cent. of albumen, diminished urea, and absence of casts. Subsequent examinations made at intervals of every three days, continued to show the same condition for six weeks; after which it gradually disappeared, and at the end of three months the urine had become normal. Her general condition improved, and she entirely regained her health. Although I have made examination of her urine every two months since then, I have never detected even a trace of albumen. Knowing her health to have been good, and having had occasion to examine her urine in 1885 and 1886, and also early in the year 1887, before she took the paraldehyde, I am satisfied that the condition of the kidneys was due directly to this cause, and had the drug not been discontinued, it would have terminated in a confirmed albuminuria.

—Goodman, *Amer. Pract. and News.*

Antiseptic Precautions in the Hygiene of Newborn Infants.—Epstein considers that our knowledge and opinions in regard to infection and infectious diseases have thus far taught us nothing in regard to the treatment of a disease which is already in progress. In other words, there are no specific antidotes. But in the way of prophylaxis much may be done, and notably so in diminishing the mortality from pyo-septicæmia in the newborn, a disease which is common both in public and private practice. Its diagnosis at this period of life is not easy, for fever and chill may be absent, nothing can be learned by interrogating the patient, and even post-mortem organic changes may not be demonstrable. A common accompaniment of the disease is intestinal catarrh, also a marked debility which may exist from birth. The disease is rarely acquired *in utero* or *interpartum*. Septic matter from without enters most frequently by the navel, but may enter through other avenues. The danger of navel infection is greatest during the first few days of life. Infection through the mouth may occur in diphtheria, septic croup, and aphthæ. Infection may be due to the aspiration of poisonous amniotic fluid, or to contact with the diseased genitals of the mother. Sepsis may develop insidiously, and suppurating processes not appear until months have elapsed. Prophylaxis should begin with most careful treatment of the umbilical cord, the object being to produce mummification as speedily as possible. Cleanliness on the part of the physician, nurse, and mother is indispensable. Créde's method of instilling one drop of a two per cent. solution of nitrate of silver into each eye at birth should always be practised as a preventive of blennorrhœa. If artificial feeding is a necessity, sterilized milk should invariably be used.

—*Amer. Journ. of the Med. Sciences.*

Inflammation of the Vermiform Appendix.—At the meeting of the Société de Chirurgie, M. Schwartz continued the discussion on the treatment of inflammation of the vermiform appendix. He said that he had lately had three such cases in his service which presented interesting particulars. The first was that of a man, aged thirty-eight, who had been treated three months previously for typhilitis. All was going on well until, fatigued by long journeys in cabs, he felt a sharp pain in the right groin; for three days the pain remained stationary, but on the fourth the temperature went up, and the patient was seized with all the symptoms of acute inflammation of the

abdomen, with swelling in the right iliac fossa. General peritonitis following, a relapse of typhilitis was diagnosed. An incision was made over the cæcum, and behind that portion of the intestine a large collection of fœtid pus was discovered and withdrawn. No sign of perforation could be found, nor was there any foreign body in the appendix. The patient sunk rapidly after the operation, and no autopsy could be made. The second case was that of a man of sixty-five, who complained on admission to the hospital of a severe pain which he felt for a fortnight previously in the iliac fossa. A swelling was discovered in that region of no considerable extent, but other symptoms of abscess were wanting; however, dullness on percussion was manifest. The exploring needle revealed the presence of matter, and the usual operation was performed. The man made a complete recovery. The third case was that of a woman, which presented the same symptoms. She did not survive the operation. In concluding, M. Schwartz said that these cases proved first—the difficulty of making a satisfactory diagnosis, and second—the necessity of prompt interference. M. Reclus was not of the same opinion, however. He considered that the diagnosis was generally easy, but unless perforation was thoroughly suspected, an early operation should be discountenanced.—*Med. Press and Circular.*

Neuritis of the Viscera.—There is, perhaps, no field of medicine in which greater difficulties are to be found, than in dealing with some of the cases of obscure and persistent pain as it is often met with in the abdominal region. Much has been written on the subject of visceral neuralgia, its causes and treatment; but nothing on the condition of visceral neuritis. On the subject of multiple neuritis there is now a good deal of literature. Some valuable work has been done by Leyden, Buzzard, Seguin, Dana, Gowers, and I may mention several articles by myself on Peripheral Paraplegia, Ascending Paralysis, Pseudo-Tabes, etc. This case I am now dealing with happened last winter during the epidemic of la grippe. A short time after the attack of influenza had passed off, the patient, a lady in her fortieth year, began to complain of paroxysms of pain of a most agonizing character. These attacks might occur at any hour in the day; but were generally most likely, and most severe, towards morning. Despite all efforts to relieve the patient, the case gradually grew worse, and she died after a period of great suffering lasting ten weeks.

The examination of the nerves and ganglia throughout the abdomen showed them to be in a highly inflamed condition. Under the microscope there was marked degeneration in some of the nerve tissue.

Here we have a sufficient explanation of the violence of the pain suffered, and of the stubborn and incurable nature of the illness. There is no reason why there may not be an attack of neuritis affecting the viscera, causing some of the obscure cases we meet with. Neuritis of the peripheral nerves is now a well established condition. It is hoped that this case may induce others to look for examples of neuritis in the abdominal and thoracic cavities.

—Ferguson, *Alienist and Neurologist.*

Albuminuria in Children.—Dr. Seyournet, in the *Union Médicale du Nord-Est* describes a form of albuminuria which he considers is more frequent than is generally supposed among children. It differs from the scarlatinal type usually observed. He studied the former type amongst children of the age of from eleven to sixteen months. A great many of the patients had been brought up on the bottle, having been fed on unsuitable food, causing distension of the abdomen or stomach, or occasionally enlargement of the liver, or intestinal disorders, accompanied by vomiting or diarrhœa. He believes this special form of albuminuria to be of an infectious character, and traces it back pathogenetically to certain toxic substances which are generated by abnormal fermentation in the bowels. These substances are absorbed by the bowels, and pass to some extent into the kidneys. They produce congestion in the renal tissue, which may lead to inflammation of the kidneys. One of Dr. Seyournet's little patients had scarlet fever twenty-two days after convalescence from this albuminuria. It is evident from this fact that it was not scarlatinal albuminuria. It was usually accompanied by anuria, whereby the congested condition of the kidneys was intensified. With some of the patients the daily evacuation of urine was only half an ounce. In one case the patient passed no urine for more than forty-eight hours. Notwithstanding this, no uræmic symptoms appeared. It was in most cases only the anuria which led to the urine being examined for albumen. The result of the examination in each case was positive. A strongly-marked feature of this disease is the œdema of the feet, sometimes also of the hands, and of the eyelids and face; but the latter were not always affected. The quantity of albumen varied from a drachm to ten drachms per diem. The duration of the disease was from two to four weeks. The treatment consisted in giving milk, which, in some cases, was mixed with lime water. Where there was vomiting, gentle aperients, such as castor-oil or calomel, were given; salicylate of bismuth was employed, in order to disinfect the bowels as much as possible. Systematic massage of the lumbar regions was also employed, in order to relieve the congestion of the kidneys.—*Lancet.*

Vulvar Œdema Complicating Pregnancy.—Œdema of the vulva sufficient to entirely occlude the vaginal outlet, with eclampsia threatening to supervene at any moment, invites a report of the following case:

M. L., twenty-two years old, Irish, domestic, primipara, in the last fortnight of pregnancy, was admitted to the Lying-in Department of the New York Polyclinic Hospital, February 6, 1890. Her health had been excellent previous to her pregnancy. Nothing indicative of kidney disease had been observed.

On physical examination the lower limbs were found highly œdematous. The right foot measured around the instep, 24.1 cm.; the left foot, 26.7 cm. The right ankle measured 28.3 cm., and the left ankle 33.3 cm. The skin, at the most distended portion, was much thinned, and apparently at the limit of distension. The œdema extended to the knees. The vulva was enormously swollen.

The right half received the greater part of the infiltrated serum, causing the labium to bulge over and occlude the vaginal orifice, the left labium being almost entirely concealed. The infiltration was extending to the left labium and buttock. The labial swelling on the right side measured, in the anterior median line, 18.1 cm.; in the transverse median line, 16.3 cm., and in the entire circumference, 31.1 cm. At the lower portion of the swelling was a pin-hole opening, through which pus was exuding. The limit

of distension without rupture was here reached, the skin being quite translucent.

Abdominal palpation revealed a characteristic primipara condition.

The abdominal wall was firm, tending to oppose free expansion and elevation of the uterus. The latter was firm, hard, and of average size. The fœtus was lying with the occiput extending to the left transverse. The amniotic fluid being scant, fœtal movement was limited. The head rested very firmly in the pelvic inlet. The urine was strongly acid, odorless, of syrupy consistence, turbid, and of yellow color. Specific gravity, 1027; quantity passed during the first twenty-four hours, 37½ ounces. There was a flaky, whitish sediment. Albumen to the amount of $\frac{1}{10}$ per cent. was present. There were granular casts, a few hyaline casts, and an abundance of pus-cells—the latter probably coming from the tumor. Perspiration was profuse.

The patient suffered from vertigo, frontal headache, occasional flashes of light before the eyes, dyspepsia, nausea, and vomiting. She stated that the œdema in the lower limbs first appeared two weeks before, and gradually increased in amount. The labial swelling began three days before, and became severe in twenty-four hours. It was due, as she thought, to her being obliged to work hard, standing all day.

The group of symptoms present in this patient, pointed emphatically to the imminence of eclampsia. She was given a general warm bath, followed by an enema of one ounce of sulphate of magnesia. The foot of her bed was elevated, and pillows were placed under her legs. The external genetalia were washed with a 1–3000 corrosive sublimate solution.

She was then given *per os*, $\frac{1}{100}$ of a grain of nitroglycerine every three hours. The bowels moved freely. Within the twenty-four hours following the administration of nitro glycerine, 67 ounces of urine were passed, an increase of 29½ ounces over the preceding twenty-four hours.

Albumen diminished to $\frac{1}{24}$ per cent., a relative and actual reduction. The œdema diminished slightly in the right limb, remained stationary in the left limb, and increased in the vulva by extension to the left labium and buttock.

Numerous punctures under antiseptic precautions were made in the inferior portion of the right labium, the fluid squirting out in little streams at first.

The swollen parts were covered with gauze soaked in sublimate solution, and a folded blanket laid on top to secure gentle and continuous discharge of the serum. In twelve hours the vulvar swelling had almost entirely disappeared. Twelve hours later I undertook, in the presence of the obstetric class, external podalic version with the object of removing the head pressure from the pelvic inlet, believing that most of the unfavorable conditions present were csused by the impacted head interfering with the pelvic and crural circulation. I did not object to precipitating labor, the time for the confinement having arrived. I employed Wigand's method in the manner practised by me in a series of cases reported in *The Medical Record* of May 26, 1888, but found the mobility of the fœtus so slight that the head could not be disengaged with reasonable effort, and ceased further attempts. Labor ensued in ten hours, perhaps excited by my manipulation. After a normal labor, the patient experienced no further difficulty, all the abnormal conditions gradually disappearing.

An interesting question arose in this case. Had eclampsia supervened before the reduction of the vulvar swelling was accomplished, would not a Cæsarean section have offered greater safety than a vaginal delivery which involved from twelve to twenty-four hours for the reduction of the tumor, the excitation of labor, and cervical dilation and delivery?

This question did arise, for eclampsia seemed probable, and was decided in favor of abdominal section, for the following reasons: the mortality in cases of Cæsarean section rests to-day at 27.52 per cent. in the total results of all countries, and, better still, only 15 per cent. in Germany.[1]

On the other hand, the mortality from eclampsia beginning before labor, is given by Galabin[2] as 50 per cent., and Löhlein[3] as 40.05 per cent.

Eclampsia is generally the product of temporary functional or mechanical derangement of the circulatory or eliminative apparatus, or both. That Cæsarean section performed before the convulsions of eclampsia could have caused much cyanosis or coma, would exert a favorable influence in restraining the spasms, is reasonable. That at this stage the eclampsia would not have produced conditions unfavorable to a Cæsarean section is likewise reasonable. This patient presented more favorable conditions than the average for a successful Cæsarean section, and much more unfavorable than the average in the eclampsia arising before labor, had it occurred with the cervix beyond our reach for twelve hours. With a statistical record of at least two deaths from eclampsia to one from Cæsarean section, the latter certainly seems the more conservative procedure.

—Ayers, *Int. Jour. Surgery.*

Treatment of Tubercular Joint Disease.—Dr. W. Watson Cheyne in an article in the *Lancet* on "Expectant Treatment versus Operative Interference in Cases of Tubercular Joint Disease," says: We may at once divide cases of tubercular joint disease into two great groups from the point of view of the question under consideration—viz., those in which chronic suppuration has occurred and those in which there is as yet no visible breaking down of the tubercular desposits. Cases in which chronic suppuration has occurred, leaving out of account for the present those in which the abscesses have burst before the patient came under notice, are no longer suitable for expectant treatment, for the day is now past when chronic abscesses should be allowed to burst or left in hope of their absorption. It is not part of my subject to go into the treatment of chronic abscesses, or, indeed, into any form of operative treatment; but I may say that while I do not at all agree with the dictum laid down by Mr. Barker that the occurrence of suppuration in hip-joint disease (I do not know whether he applies it to other joints or not) is an indication for excision, I think that when suppuration occurs the whole question of operative measures should be carefully considered, and in any case we can now procure more rapid and more certain recovery by operative measures of a somewhat more severe character than simple aseptic drainage, although by that method we have had many excellent results.

---

[1] Dr. Harris, in the *American System of Obstetrics*, Vol. II, page 260, records 80 cases in Germany, with 12 deaths and 38 operators; and a total of 108 recoveries in 149 cases in the hands of 82 operators in various countries.

[2] In the *American System of Obstetrics*. Vol. II, page 76, Galabin records the mortality of cases arising before labor as 50 per cent., during labor as 25 per cent., and after labor as 8 per cent.

[3] In *Lusk's Obstetrics*, page 564, Löhlein gives the mortality as 40.05 per cent. before, and 6.66 per cent. after, labor.

Medical News and Miscellany.

THE quarantine has been removed from the Spanish ports east of Gibraltar.

THE State Board of Health, Pennsylvania, recommends a regulation forbidding the importation of Spanish rags.

ACCORDING to medical classics, the use of meat in summer causes more diarrhœa than fruits; the meat spoils quickly in hot weather, and acts as an emetic or a purgative.

AS a local anæsthetic, Dr. J. B. Mattison recommends a spray of the following compound, viz.: Menthol, one drachm; chloroform, ten drachms; ether, fifteen drachms.

DR. NARCISO CARBÓ DE ALOY, Professor of Therapeutics in the University of Barcelona, died on November 5. He was a successful teacher, and contributed largely to Spanish medical literature.

PROFESSOR LEWIN, the well-known authority on syphilis, who has been disabled by illness for more than a year, has now recovered sufficiently to resume the duties of his chair in the University of Berlin.

MESSRS. JOHNSON & JOHNSON, wholesale druggists and manufacturers, are the owners of a large factory and laboratory in New Brunswick, New Jersey, which stands as a monument to their enterprise and genius.

A WOMAN living near East Dubuque, Illinois, has given birth to a child without eyes and with no place in the head for them. The forehead extends down to the nose perfectly smooth. Physicians say the child will live.

DR. EDWARD M. HARTWELL, associate in Physical Training and Director of the Gymnasium at Johns Hopkins University, has resigned to accept the position of Director of Physical Training in the public schools of Boston.

ALL soldiers who lost limbs during the war can have artificial ones supplied by the government if they will ask for them. They can get a new one every five years; or, if they prefer, they are paid its cost value instead. Legs cost $75, and arms, $50 each.

"WHO'S AFRAID."

The learned physicians tell us there is danger in a kiss;
Disease and death may reach us through that avenue of bliss.
The gentle osculation which our being wildly thrills
May bring us months of sickness and a lot of doctor bills.
They say that with the honey we are all so prone to sip
The deadliest bacteria may pass from lip to lip.
But when a fellow gets a chance to kiss a pretty maid
He's very apt to say: "Oh, hang the doctors! Who's afraid?"
—From the *Chicago Post.*

NEW MEDICAL JOURNALS.—The first number of the *Balneologisches Centralblatt*, a fortnightly periodical, dealing, according to its title page, with "balneotherapy, hydrotherapy, massage, curative gymnastics, hygiene of bathing, and dietetics," appeared at Leipzig on October 3. It is edited by Dr. Franz C. Müller. Hirschwald, of Berlin, announces that the first number of a new journal, devoted to sanitary matters, will appear on January 1, 1891, under the editorship of Professor Carl Fraenkel, of Königsberg, and Dr. Erwin von Esmarch, *Privat-docent* in the University of Berlin, who is at present lecturing for Professor Koch.

AT a meeting of the Board of Judges recently, a memorial to the General Assembly was adopted, asking that the Judges be relieved of the duty of considering applications for liquor licenses.

Among appointments to the Board of Education were C. W. Findley, Sixth Section; Dr. Thomas G. Morton, Ninth; Dr. Alex. McAdam, Twelfth; Herbert Welsh, Twenty second; Thomas Shallcross, Thirty-fifth.

A GALVESTON woman has sued Dr. J. J. Burroughs for damages said to have been incurred through her incarceration in an insane asylum.

We must repeat our caution against physicians signing certificates of insanity without the clearest proof. The best rule is to refuse to sign unless the physician can himself elicit from the patient such proofs as would convince an ordinary jury of the man's insanity. Never rely on the statements of patients' relatives, or on other heresay evidence.

INEBRIETY AND LIFE INSURANCE.—The American Association for the Study and Cure of Inebriety, will hold the first of a series of monthly meetings at the hall of the New York Academy of Medicine, on Forty-third street, December 10, at 8 P.M.

The subject of the evening will be presented by papers from Dr. D. T. Crothers, of Hartford, Conn., on Alcoholic Inebriety and Life Insurance, and Dr. J. B. Mattison, of Brooklyn, N. Y., on Opium Addiction and Its Relation to Life Insurance. Other leading physicians will participate in the discussion.

The medical public is cordially invited.

THE influx of American physicians to Berlin to study Dr. Koch's method of curing consumption is less than was expected. So far only three have registered their names at the American legation. They are Dr. Samuel G. Dixon, who represents the Jefferson Medical College, of Philadelphia; Dr. John Guiteras, of the University of Pennsylvania, of Philadelphia, and Dr. Herring, of New York.

Dr. Uterintschen, of St. Petersburg, has prepared a paper for the purpose of proving that the Brown-Séquard emulsion, or elixir of life, which created such a stir at the time of its discovery, has a similar effect on tuberculosis as Professor Koch's lymph. Eighteen patients have been inoculated for the purpose of demonstrating the result.

MUTUAL AID ASSOCIATION OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY. — In order to awaken an interest in the work of this association, and enlarge its field of usefulness, the regular meeting of the County Medical Society occurring Wednesday evening, December 10, will mainly be devoted to a consideration of its objects.

It is expected that Dr. Gouverneur M. Smith, late President, and Dr. Henry Tuck, President of the New York Society for the Relief of the Widows and Orphans of Medical Men, will be present and give a brief review of the successful career and present prosperous condition of the society which they represent.

A short memoir of Dr. Henry Hollingsworth Smith, one of the founders of the association, will be read by Dr. Benjamin Lee. Short addresses will be made by the President of the County Medical Society, Dr. W. W. Keen; the President of the Mutual Aid Association, Dr. De Forest Willard; Prof. D. Hayes Agnew, Prof. William Pepper, and others directly interested in this benevolent enterprise.

Immediately after adjournment, a reception will be tendered to the guests of the association from New York, at the University Club, 1316 Walnut street.

SLEEP.—How many hours' sleep do you require? As many as you can get. That is the general answer to such a question. No rule can be laid down. Jeremy Taylor thrived on three hours, and so did Cardinal Newman. Many centenarians are contented with five hours, but some of them require eight or nine. Unless you are afflicted with a pronounced insomnia—a thing widely different from occasional and even troublesome wakefulness—you are foolish to employ any kind of narcotic drug. But there are two rules of sleeping that everybody may adopt without hesitation: 1. Never let yourself be awakened by anybody else, but wait until you have slept out your sleep. 2. Get up as soon as you wake. If you follow these two rules, the hours of sleep will very soon regulate themselves. If you read yourself to sleep, you should read a heavy book, not a light one—a book that taxes and tires your brain, not one that stirs and stimulates it. A dull book is good, a stupid one is better.—*St. James Gazette.*

PATENTS, ETC., on medical subjects, issued November 25, 1890:

Liquid-evaporating apparatus (3 patents)	J. A. Morrell	Landsdale, Pa.
Evaporating liquids	J. A. Morrell	Landsdale, Pa.
Insecticide	F. Jones	Morse, Kansas.
Obstetrical forceps	A. B. Lyman	Baltimore, Md.
Making vegetable pepsine	V. Marcano	Caracas, Venezuela.
Making peptones	V. Marcano	Caracas, Venezuela.
Making peptonized meat	V. Marcano	Caracas, Venezuela.
Concentrating solutions and extracting solids therefrom	J. A. Morrell	Caracas, Venezuela.
Concentrating solutions	J. A Morrell	Caracas. Venezuela.
Syringe, (2 patents)	W. W. Guptill	Boston, Mass.
Artificial tooth	F. T. Van Woert	Brooklyn, N. Y.

Clinical Lecture.

CHRONIC METRITIS WITH ENDOMETRITIS. UTERUS DILATED AND CURETTED.

BY E. E. MONTGOMERY, M.D.,

Professor of Gynecology in Medico Chirurgical College, and Obstetrician to the Philadelphia Hospital.

GENTLEMEN:—The patient I bring before you is a woman forty-eight years of age, married, mother of four children, has never had a miscarriage. She has been suffering for the past two years from a sensation of weight in the pelvis; from irregular menstruation, and from frequent discharge of blood, which has led to her being exceedingly anxious as to her condition, and desirous of having a careful examination to determine its cause. Hemorrhage occurring at this time of life may be attributable to a number of conditions. Thus, it may arise from an inflammation of the mucous membrane of the uterus, which complicates a chronic inflammation of the organ. It is, or it may be, the result of growths in the wall of the uterus, such as fibroids; or from malignant disease, which may be in the form of epithelioma, carcinoma, or sarcoma. Every patient suffering from irregular menstruation, and particularly at the period near the climacteric, should be submitted to careful examination, as it is only by prompt discovery and treatment that malignant disease of the uterus can be successfully relieved. Upon examining this patient we find that the cervix is apparently free from disease, the body of the uterus is enlarged, is slightly indurated and tense; it is regular in its outline, and is freely movable. If we had to deal with malignant disease, we would find that it had developed, most likely, from the cervix, and this would be very hard, dense and resisting, with probably some ulceration upon its surface, or there would have been marked cell-proliferation and the development of a condition resembling a cauliflower growth, filling up the vagina; the surface of this growth would be exceedingly friable, so that the introduction of the finger into the vagina would give rise at once to a bleeding. The absence of such condition enables us to say that this patient is not suffering from cancer of the cervix. Before entirely eliminating the possibility of malignant disease, we should remember that in 2 per cent. of the cases in which the uterus is the seat of the disease, it may affect the body of the organ, beginning in its mucous membrane, or in the glands of the mucous membrane. In such cases hemorrhage and an offensive discharge would be prominent symptoms. By examining the cavity of the uterus by means of a blunt curette, in such a case, we would expect to find that portions of the tissue would be broken off and free hemorrhage would follow. We have subjected this patient to an examination of this character, demonstrating the fact that malignant disease does not exist.

If there was a fibroid growth within the walls of the organ, we should expect to find some irregularity, and that the uterus was not regularly developed. The examination of this patient fails to disclose any indications of this character. It is important to remember, however, that these growths may be small in size, and may have been forced into the cavity of the uterus, and are not sufficiently large to give rise to marked symptoms. A case of this character came under my observation a year ago, in this hospital. I removed the uterus for supposed malignant disease of the body; examination of the organ subsequently disclosed the fact that we had a fibroid not larger than a hickory-nut projecting into the uterus, and from this the hemorrhage had taken place. To make sure, then, of the conditions present, we propose to dilate the cavity of the uterus sufficiently to permit the introduction of the finger for careful exploration, as by no other means can we so successfully determine it. Now you will ask how the uterus can be dilated. For this purpose various methods of procedure have been instituted. The introduction of graduated bougies, increasing the size until the organ is sufficiently dilated as to permit the introduction of the finger; these instruments, however, necessarily produce traumatism of the mucous membrane and increase the danger of septic troubles. Another method is by use of mechanical dilators—instruments which dilate by the separation of parallel blades. These instruments are very much eulogized for the treatment of many conditions of flexion of the uterus, and for the relief of pains resulting from dysmenorrhœa. Their use, however, leads to bruising and laceration of the walls of the uterus, and unless the patient is carefully treated subsequently, may cause septic trouble to extend into the tubes and pelvis. The former method of dilatation was by the introduction of various forms of tent, such as the sponge, laminaria, or tupelo, the objection to these methods of dilatation is the difficulty in rendering them aseptic, and the danger from septic germs. I have frequently seen, in the practice of others, inflammation excited in the pelvis, following the insertion of the sponge tent, which would require prompt operation for the relief of the patient, or where it was neglected, lead to her death.

The plan we have pursued in this patient has been the dilatation of the cervical canal by the introduction of iodoform gauze; the vagina being first thoroughly and carefully disinfected, the gauze is pushed into the cavity of the uterus, and caried up to, or through, the internal os, and the cervical canal packed tightly with it. The gauze, through its capillary action, drains the cavity of the uterus, and does not favor decomposition or the development of germs that may be present. When the first packing is removed, the uterus will be found considerably dilated; the parts should be again disinfected and a larger quantity of the gauze introduced. This patient has in this way been packed three times, and the uterus is so dilated as to readily admit the introduction of the finger into its cavity. In so doing, we find an entire absence of any projection into it, such as would be present if we had a submucous or interstical fibroid. We are left, then, with the conviction that while hemorrhage arises as the result of the chronic inflammation in the uterus, accompanied, as it is, with inflammation of its mucous membrane; the hard, dense feeling, with the enlargement of the uterus, is due to a condition which is known as areolar hyper-plasia, or sclerosis of the uterus. This condition is a sequel of sub-involution, the organ is considerably enlarged, and, as a result, undergoes a substitution of fibrous for its muscular tissue, producing the condition of which we have spoken.

For the arrest of the bleeding, we will curette the cavity of the organ, thoroughly wash it out with a disinfectant solution, and make an application of chromic acid. In order to make sure of sufficient drainage, we will pack it with the iodoform gauze and place a pad of this gauze in the vagina beneath the cervix. By such a method of treatment we will accomplish much more than we could by subjecting this patient to repeated applications of remedies to the cervical and uterine canal, as is ordinarily done, by wrapping the applicator in cotton, dipping it into a solution and passing it into the organ; in this method, the greater part of the fluid is squeezed out at the external os, and the internal portion receives but little more than the irritation produced by the introduction of the instrument. In this case, the dilation of the uterus, by the tampon, has a very beneficial effect upon the swollen and inflamed mucous membrane, promoting the absorption of exudations that may be present; it also has an alterative effect upon the uterus, and in cases of sub-involution has a valuable influence in reducing the size of the organ, producing, as it does, more rapid circulation.

LACHRYMAL OBSTRUCTION.—A SUCCESSFUL BUT NEGLECTED METHOD OF TREATMENT.

By JOHN S. STEWART, M.D.,
PHILADELPHIA.

THE flowing of the tears over the cheeks instead of through the natural drainage system of the eye into the nares, constitutes one of the most frequent and, for the most part, unsatisfactory conditions the ophthalmic surgeon is asked to relieve. In the majority of these cases the ordinary and approved form of treatment is undertaken, and, for awhile at least, both patient and consultant are sanguine as to the results. Weeks, possibly months or years, roll by; meanwhile numerous visits have been made by the more and more discouraged patient, lachrymal probes of the sizes within the prescribed limits of the text-books have been repeatedly inserted for the purpose of dilating the existing stricture, much suffering meanwhile endured, and, although some benefit probably has been derived, the overflowing of the tears continues. Disappointed, discouraged, financially embarressed perhaps, frequently with a feeling of ill-will for the profession generally, and certain of its members in particular, the patient stops all treatment, being thenceforth more of a sufferer than the inexperienced can imagine, and liable to ever increasing disfigurements about the eyes and face.

Interference with the natural flow of tears from the conjunctival sac may be due to one or more of several causes, and this must first be determined before the possibility of success in treatment can be given thought.

Closure or displacements of the puncta, which may be congenital, but are usually acquired, the result of injury or of inflammation, are not the most frequent causes of the condition known as *epiphora*. The history of the case, together with a thorough examination of the parts, both in the way of inspection and by attempted insertion of a delicate probe, will reveal whether the trouble be located at this point.

Strictures of the canaliculi or nasal ducts, particularly of the latter, will be found the cause in the majority of cases of this most annoying condition. These strictures may be produced by injury, disease of the maxillary or nasal bones, or by pressure of neoplasms, but are the result usually of extension of inflammation from the nasal or naso pharyngeal mucous membranes; likewise in some cases the inflammation may extend downward from the conjunctiva. Consequent upon the obstruction, however produced, and the accompanying catarrhal condition of the mucous tract, together with the retention of decomposing tears in the lachrymal sac, there is usually more or less swelling in the region just below the inner canthus of the eye. Pressure with the finger-tip upon the integument covering the sac may cause the expression of a viscid or muco purulent fluid, either through the canaliculi into the conjunctival sac, or downward into the nasal duct. This condition, usually described as *mucocele* or *chronic dacryocystitis*, is liable at times to assume an acute form, constituting what is know as abscess (phlegman) of the lachrymal sac. A serious complication may now arise if the pus find exit through the anterior wall of the sac instead of being discharged through the canaliculi or into the nasal duct. In many of these cases a permanent and disfiguring fistula is established in the cheek just below the region of the sac.

The causation and pathology of this affection are much better understood than is its treatment successful; the latter, therefore, will occupy the remainder of our attention at this time.

The usual and almost routine method of treatment in these cases has been the slitting through of the lower canaliculus to the sac, thereby transforming this tube-like structure into an open gutter or trough. When this has been accomplished the various sizes of probes are inserted through the sac and into the nasal duct at intervals of a few days, care being taken to keep the walls of the canaliculus from adhering, also that false passages be not made by means of the probe.

Were the mechanism of the exit of the tears from the conjunctival sac through the puncta and canaliculi better understood, or less of a mystery, the routine destruction of the canaliculus might not occur, but be reserved for those cases absolutely requiring the operation.

When in the act of winking the lids are brought in accurate contact and firmly pressed upon the ball, a more or less perfect vacuum is formed in these canals; immediately upon the termination of this act the tears pour in to fill the vacuum, and are then carried on during the next closure of the lids by the action of certain fibers of the articularis muscle which invest the walls of the canaliculi and sacs.

Thus it can be seen that the indiscriminate obliteration of this function may in certain cases produce results more disastrous than the condition already existing.

The treatment the writer employs, and which he would suggest as the first means to be adopted in these cases, is the repeated passage of the smallest size of probe (if possible) through the punctum, canaliculus and nasal duct, until relief has been obtained. At the same time, in connection with this, it is of the utmost importance to give attention and persistent treatment to the cause of the trouble, wherever it may be located.

When the conservative method just described has failed in giving satisfactory results, or has been found impracticable, there can be no longer any objection to slitting of the lower canaliculus; and it is in these cases that a rarely employed method of treatment is recommended.

The repeated passage through the nasal duct of probes of various sizes in many instances, no doubt, has proved of benefit; occasionally permanent cures are known to be effected by this means, when judiciously employed in connection with treatment of the naso-pharyngeal mucous tract. On the other hand, probably a greater number remain but partially relieved, and some few are left either no better or quite possibly in a worse condition.

The probe, even when in the hands of the most skilled, must nearly always, of necessity, injure, or perhaps tear, the delicate mucous lining of the duct, at the points where the strictures are located, if at no other. A new inflammatory action is thus started, to be followed in the process of healing by still further contraction of tissue and lessening of the lumen of the duct. Injections of antiseptic washes and astringents, by use of the lachrymal syringe, prove beneficial in some instances; frequently, however, more serious lesions are produced by this means than with the probe.

In addition to the already enumerated discouragements to be met with in the use of the generally accepted methods of treatment in these cases, patients frequently will not, or can not, make the required number of visits; so that from the outset the prospect of success is anything but favorable.

In most of the text-books of ophthalmology, insignificant mention is made of the use of the silver style; but the lead wire usually mentioned in the same connection seems to have been more generally employed in practice, and then only in obstinate cases. The writer desires to call attention to the fact that most gratifying results can be obtained by the use of the canulated silver style, this being specially true of cases of long standing trouble.

The proper insertion and action of this simple and inexpensive instrument requires that the lower canaliculus be first s it; after this has been done and the nasal duct explored by means of an ordinary probe, a style of the proper thickness, curvature and length is selected and inserted its entire length into the canal, the upper bent portion resting easily and without friction in the bed of the canaliculus.

If a properly fitting style has been selected, there will be but little pressure anywhere; and the upper portion being nearly concealed does not often cause discomfort or irritation to the eye or nose. After a few hours, excepting the cases of children or very nervous individuals, its presence is rarely noticed. Should there be any pain following insertion, the persistent use of hot strips applied near the inner canthus of the eye, usually affords relief. The great advantage of the hollow style over the lead wire, is the artificial channel thus made as an exit for the tears; and this result almost certainly follows if a properly fitting instrument has been inserted. The relief to the patient, resulting from the proper drainage of the tears, is almost instantaneous.

After some weeks or months the style may be removed and a permanent cure of the affection expected. Should the relief be found only partial after removal of the instrument, the majority of patients, having become unconscious of its presence, will prefer to wear it permanently rather than suffer as before.

1716 CHESTNUT STREET.

THE SUBSEQUENT HISTORY OF A CASE OF SYMPATHETIC OPHTHALMIA.

By HOWARD F. HANSELL, M.D.,
Chief Oph. Dep't Jefferson Medical College Hospital.

IN 1882, Miss H., aged fifty, applied at the Out Patient Eye Department of Jefferson College Hospital for relief from blindness and pain in the left eye, and for increasing dimness of vision and pain in the right. Upon inspection of the left eye, a melanotic tumor, probably proceeding from the choroid, associated with cyclitis and iritis, was diagnosed. The right eye had sympathized to the extent of a moderate iritis with a few bands of exudation between the iris and the lens capsule. The treatment conducted under the supervision of Prof. Wm. Thomson consisted of enucleation of the left eye with energetic mercurialization, and local treatment of the right with atropia and hot water. The sympathetic iritis soon subsided, and the patient left the hospital with a fair amount of vision in the right eye. (The records of the case at its earlier stage are not accessible, and I am obliged to depend on my memory and the patient's statements for the above facts.)

In June, 1890, Miss H. returned to the hospital with the following history: Until one year ago, she had been able to use her eye for all ordinary purposes, including reading; but at that time she noticed her vision gradually growing less, necessitating the abandonment of one after another of her occupations, until finally she became totally blind, with the exception of an indistinct perception of light as she faced a window or open door. She had never worn an artificial eye in the left orbit. The condition in June, '90, was: Cornea, clear; anterior chamber, free from deposit, and somewhat deeper than normal; a few small adhesions between the papillary border of the iris and the lens capsule, and the lens entirely opaque and slightly dislocated backward; no pain; light perception was undoubtedly present; light projection uncertain. She could see the illumination of a lighted gas-jet in the dark room, but she could not positively say from which direction the rays of light entered the eye. Although a good prognosis of a cataract extraction could not be given, and a plain statement of the dangers was made, Miss H. decided to take the chances of a favorable result of an operation. At her urgent request, I decided to make an effort to extract the dislocated lens, by means of a small fork devised by me, and described in the *Med. News*, March, 1889.

The withdrawal of the Græfe knife after the incision through the corneo-scleræ border was followed by a bead of vitreous. An iridectomy upward was the occasion for a still further loss of vitreous. The fork or extractor was now inserted behind the lens to a point about two thirds the way down the posterior surface. The small barbs fastened in the lens substance, and by slow, steady traction the lens were brought out through the cut. Another small portion of vitreous escaped. The eye-lids were closed immediately. A soft compress of cotton anointed with vaseline was applied to the lids and moderate pressure exerted by means of a roller bandage. After several days the eye was inspected, and the edges of the cut were found to have united. No iritis developed, and the healing progressed as favorably as after an uncomplicated extractive operation. The patient left the hospital in ten days, with instructions to return in order to be fitted with a glass. The operative manipulations were conducted under antiseptic precautions. The final result was far in excess of my anticipations. Vision with her proper sphero-cylindrical correction $= \frac{20}{200}$, and admitted of Miss H.'s reading large print.

The success of this operation encourages me to call the attention of the profession to this simple instrument for the extraction of dislocated lenses. I feel warranted in believing that no other instrument with which I am acquainted could have been employed with an equally good result. Miss H. is the third case in which I have used it and in each the extraction has been accomplished in an entirely satisfactory manner. Dr. Knapp (*Arch. Ophthal.* January, 1890) advises in the majority of cases the expulsion of the cataractous lens through the cut by external pressure, and not by means of instruments. In the cases in which I have operated this manœuver would have been impracticable, since in all three prolapse of the vitreous occurred after the incision, and pressure would have necessarily caused great loss of vitreous, and probably collapse of the ball, with the lens undelivered.

I take this occasion to warn the operator who might feel inclined to use the fork, that great care must be exercised, lest the instrument be pushed too far downward, and instead of fastening its barbs into the lens might become entangled in the ciliary body—an accident greatly to be deplored, of which I have been a witness.

252 SOUTH SIXTEENTH STREET.

DR. ERNEST WENDE, in an article in the *Buffalo Medical and Surgical Journal*, urging the therapeutic value of electricity, says:

Recently a most fruitful field in galvano-therapeutics has been opened up, and notwithstanding that the science of electro-therapeutics is largely experimental, the progress in the use of the continuous or constant current has been rapid, improved apparatus, improved and accurate modes of application, effects carefully ascertained and certified, have done away with the vagueness of aim and the uncertainty of result. Well-directed experiments and fresh discoveries have closely followed each other.

With due regard to justice, I must admit that in the majority of cases thus treated, the method is tedious and generally unsatisfactory, when the term cure comes into question, yet always palliative when relief is asked for—however, there are cases of superficial epitheliomatous ulcers of the non-infiltrating variety—surrounded by comparatively little induration, which may be dealt with most successfully with electro-puncture. Then, again, the intelligent use of this agent cannot be too strongly recommended in operations about such an important structure as the eye, where you are anxious only to destroy diseased tissue. The other advantages possessed by this treatment may be said to be that—

1. It delays the growth, even if it does not always cure.
2. It allays pain.
3. The patient is not necessarily confined to his room.

This method possesses advantages offered by no other form of treatment. As you are aware, excision often produces profuse hemorrhage, which may be difficult to control. Electrolysis causes no bloodshed. Caustics, such as nitric and chromic acids, may be vulgarly termed nasty, as they are likely to spread, discoloring the parts and often producing scars. Electrolysis is cleanly and localized in its action and produces no scars. The actual cautery is no better than caustics. Ligation is tedious and uncertain. Electrolysis is certain and rapid.

Society Notes.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

THE RENAL STATUS OF OPIUM HABITUÉS.

THIS paper, read October 22, 1890, by J. B. MATTISON, M.D., of Brooklyn, enters a field which, so far as we are aware, has not been largely worked at home, and is preliminary to one that will include, it is hoped, the opinions of other leading pathologists here and abroad.

Its present scope is mainly the views of American observers whose high repute entitles them to large respect. It will present opinions pro and con; it will offer such clinical, chemical, and microscopical evidence as has passed into history touching the topic under discussion; and it will give details of some pertinent cases that have come within the reader's personal range.

Until recent years it was largely held that while the habitual use of opium gave rise to well marked, often grave, functional disorder, it did not, like alcohol, cause structural lesion. Of late, however, there has been a growing consensus of opinion that this view is a mistaken one, and that in a fairly large proportion of cases, its continued taking—especially morphine hypodermically—will induce renal changes ranging from slight hyperæmia to profound organic derangement, ending in death.

Reaching the pith of this question, three queries were presented:

Will the habitual use of opium in any form cause organic renal disease?

If so, what lesion is most likely?

What is the *rationale?*

Roberts Bartholow: "I have made numerous observations on the effects of opium on the urine, but with negative results. The reason for this appears to me to be rational. The action of opium or morphine, used habitually, tends to diminish excretion by lessening the activity of the kidneys. The effect on the kidneys is, therefore, rather soothing and grateful to these organs. In lessening action, the blood-supply to the kidneys is diminished, congestion is prevented, and the organs carry on their functions with less strain."

Francis Delafield: "It has not seemed to me that opium is a cause of any kidney disease."

Thomas E. Satterthwaite: "In two post-mortems of patients who died of opium poisoning, the kidneys showed no structural change, although in one patient these organs were swollen and congested."

Herman M. Biggs: "Of all the autopsies that I have seen in these cases, I have been impressed with the marked chronic congestion of the kidneys. This is frequently, and, I think, generally, associated with a uniform increase in the interstitial connective tissue of the organs. The kidneys are of a very deep, uniform red color, and the consistence is decidedly increased. But I very much doubt whether the habitual use of opium in itself will cause extensive organic disease of the kidneys; I mean such disease as will seriously compromise their functions. I have never seen a case of opium addiction at the autopsy, where extensive disease of the kidneys was found, that I believed was due to the effect of the opium. I do not think the changes I have stated, as a rule, seriously interfere with the performance of the renal functions."

E. H. Bartley, Professor of Chemistry and Toxicology, Long Island College Hospital: "So far as my observation goes, I have seen no reason to believe that the alkaloid exerts any direct influence to produce organic disease of these organs. It seems to be eliminated easily and rapidly by the kidneys, and without irritation. This is especially the case when given by the stomach, in which case it is eliminated almost as fast as it is absorbed. If the practice of opium- or morphine-taking has any influence in producing organic disease of the kidneys, it is rather to be regarded as an accidental or indirect one. While morphine does not seem to possess any irritant action upon the renal structure, it lessens the amount of urine passed, and retards oxidation and the elimination, and, probably, the formation of, urea. Urine so modified is more irritating than normal, less concentrated urine, and may, possibly, tend to the formation of the gouty kidney, as interstitial nephritis. This effect is aggravated by the disordered digestion induced by the alkaloid. When morphine is self-administered, by means of the hypodermic syringe, another accidental influence is at work. Without proper care of the syringe, as to cleanliness, abscesses occasionally occur at the seat of the injection, and these tend to produce nephritis of septic origin."

John A. McCorkle, Professor of Theory and Practice, Long Island College Hospital: "I think the habitual use of opium will cause organic renal disease; that the small granular kidney is most likely, and that the reason is a low grade of inflammation induced by the elimination of a foreign substance."

J. H. Van Cott, Jr., Pathologist, Long Island College Hospital: "Based upon the supposed physiological action of opium and its alkaloids, I believe that its habitual use must be productive of renal disease. Its direct action on the vaso-motor apparatus must finally result in chronic dilation of such vessels as are controlled by the nervous system and contain non-striated muscular fibers."

Its effect upon the digestive apparatus, and the well known disturbance of primary and secondary assimilation, can hardly eventuate otherwise than in the most profound disturbance of all the so-called parenchymatous tissues; a disturbance perhaps well expressed by the term faulty retrograde metamorphosis. From any reasonable standpoint, the metabolism of cells is bound to be inhibited by the action of these narcotics, partly through vaso-motor disturbance, also through the *direct* effect of the drug on cell activity.

If, on the one hand, conditions of profound nutrition and vascular disturbance are brought about to inhibit the proper metamorphosis of all the tissues in the body, yielding only poorly-constituted products for elimination; if, in other words, the true "end-products" are not attained; and if on the other hand, the metabolic action of the very cells whose business it is to eliminate these "end-products" is inhibited—if the epithelial cells of the renal parenchyma are thus handicapped, it is inconceivable to me that they should not in time become permanently modified both in form and in functional activity.

Theoretically, the renal changes should be all those resulting from chronic renal hyperæmia—a peculiar form of diffuse nephritis, with an added parenchymatous degeneration.

Two cases of the opium disease have come under my observation, in both of which grave renal symptoms obtained. One died, and the autopsy revealed widespread chronic lesions of all the organs, the kidneys not excepted; the other is still living, having had, in the course of the summer, an uræmic attack, which nearly proved fatal.

I cannot dogmatize on the subject until more experience has been gained in the thorough, systematic, and impartial observation of the renal functions in such cases; but my experience, such as it is, all points toward the correctness of my reasoning.

Text-books make little or no mention of this topic. Wilson, is an excellent paper—Pepper's System—refers to it briefly. Niemeyer tells of interstitial nephritis due to "septic material in the blood." Roberts writes of albuminuria due to disturbed innervation. Bartholow, in Hypodermic Medication, gives negative evidence as to albumin and sugar in urine due to morphine, and thinks Levinstein's statement not applicable to cases met in this country. He further says—and this is of no mean moment as pointing to a factor in renal break-down: "The frequent use of the syringe, often the hasty introduction of the needle, and the use of a rusty and dirty needle, the injection of badly prepared solutions, the repeated injections into certain localities, have a disastrous effect. Large hard nodules form, which slowly suppurate. Extensive sloughing may take place, and septicæmia and pyæmia sometimes occur with a fatal result. In a large proportion of these morphine-maniacs suppuration abscesses of considerable size, and ulcers, are produced. I have seen the arms, the abdomen, the thighs, and legs, a mass of ulcers and of abscesses in various stages of formation." Dujardin-Beaumetz cites a fatal case of this kind, and Calval has noted many such with traumatic fever.

The most extensive, interesting, and valuable notes on this point are those of Levinstein, who observed many cases, and made frequent trials on rabbits and dogs, always getting albumen, and usually sugar. The latter he regarded as specially significant, and its relation to morphine taking, acute or chronic, of high medico-legal importance, as strong presumptive proof of the toxic agent in cases of suspected fatal poisoning from that drug.

In the absence of positive pathological facts, Levinstein thought that albumen might be due to one or all of three causes:

1. The action of morphine on the central organ which has a relation to albumen.

2. By the concurrence of anomalies in the normal pressure of the blood, causing at last intra-renal disorders.

3. By paralysis of the nerves which surround the arteria renalis. This would have the same effect as knife-cutting of those nerves, after doing which, von Wittich found albumen in the urine.

Levinstein thinks it very probable that varying blood-pressure is the leading factor. This, he suggests, explains the intermittent albuminuria common in these cases, while *continuous* albumin is due to nerve palsy of the renal artery.

Autopsic opportunities in these cases are not frequent, and the following, under the notice of Dr. Van Cott, and reported in the October Brooklyn *Medical Journal*, is of interest:

Mrs. B., aged forty years; semi invalid for years, during the last four of which she used morphine, subcutaneously; was attacked with sudden illness, having persistent vomiting, some purging, scanty, high colored, albuminous urine, which progressively increased. Later, clonic spasms of left arm, extending to entire body, like uræmic convulsions; urine almost suppressed; extremities œdematus. Death by coma and convulsion.

Necropsy.—Left larger, right smaller than normal; soft; surface studded with countless small punctiform hemorrhages. Around Malpighian corpuscles numberless hemorrhages. Microscopic—fresh, double-knife section: Most of glomeruli are hemorrhagic, extravasated blood being seen around the Malpighian tufts within Bowman's capsule. Cortex and medulla markedly congested. Epithelial cells in many tubes desquamated; many tubules have hyaline, epithelial, and granular casts; others, much granular detritus.

Conclusion: Case of microbic infection. Patient, in self-giving of morphine, drove needle through pus in left deltoid, causing systemic infection, and overstrain on kidneys already crippled by opium excess.

Since September 1, eight cases of the morphine disease have been under the writer's care, in which careful chemical and microscopical tests were made. Of these, seven gave proof of renal changes, ranging from chronic hyperæmia to structural lesion and death.

CASE I.—Physician; aged thirty-six years; kindly referred to me by Dr. Bartholow. Four years morphine-taking—eight grains subcutaneously daily. Examination disclosed such evidence of profound kidney changes that no attempt at treatment of his morphine-using was made. Patient remained a fortnight, when he showed signs of general failure, which ended in death on the eighteenth day, from lung œdema, of about twelve hours' duration.

CASE II.—Physician; aged thirty years; four years morphine-taking—thirty grains daily in one dose, hypodermically. Quit treatment prematurely, and was forced to resume the drug; is again under treatment, and will recover.

CASE III.—Layman; aged thirty years; four years morphine-taking—nine grains subcutaneously; recovered.

CASE IV.—Clergyman; aged forty-nine years; twenty-seven years addiction—twenty-three years opium, four years morphine, by mouth, six grains daily; recovered.

CASE V.—Female; aged thirty-four years; ten years morphine-taking—eighteen grains daily, hypodermically; recovered.

CASE VI.—Physician; aged twenty-eight years; four years morphine-taking—sixteen grains, subcutaneously, daily; unrecovered.

CASE VII.—Layman; aged seventy years; three years hypodermic taking—four grains daily; recovered.

CASE VIII.—Physician; aged thirty years; one year, irregular, subcutaneous taking—three grains daily; recovered.

Of these eight cases, seven had crippled kidneys, and all used the drug by needle. The twenty-seven years-taker by mouth showed no kidney lesion.

Repeated chemico-microscopical searchings in such cases have disclosed certain changes from normal renal action, and so often, that we think they may be accepted as the rule.

The urine is diminished.

The urea is lessened.

Special gravity is varied; if changed, usually lowered.

Albumin is present.

Sugar also.

The chlorides are decreased.

Casts, granular, hyaline, and waxy, are present.

Urine sediment holds epithelial cells and granular detritus.

Concluding, our own opinion, in reply to the threefold query, is:

First: Yes.

Second: Cirrhotic.

Third: A triple factor—vasomotor changes; impaired general nutrition, and inflammatory action due to non-eliminated irritant products.

Discussion.—Dr. L. K. Baldwin: I understood the reader to say that in these cases, while the urine was lessened in quantity, the specific gravity was also below normal, and sugar and albumin were present. I would ask how low a specific gravity he has noted in cases where sugar was present?

Dr. S. Solis-Cohen: I would ask Dr. Mattison what proportion of opium-users present signs of renal disease? Is the proportion of cases of renal disease larger among those who use opium than among those who do not?

Dr. Wharton Sinkler: I have listened with a great deal of interest to Dr. Mattison's paper, and my own experience, although limited in comparison with his, bears out much that he has said. I think that the use of opium, whether by the mouth or subcutaneously, does induce renal changes. In a considerable proportion of the cases under my care for the treatment of the opium habit, there has been more or less evidence of renal disturbance in the presence of albumin or casts in the urine. Frequently, however, patients are seen who have been taking large amounts of morphine subcutaneously for a long time with no evidence of renal disease. I cannot help thinking that in cases of morphine habit the renal changes cannot be very profound, from the fact that many opium habitués are long-lived. As Dr. Mattison has said, we seldom have opportunities to make autopsies in cases of the opium habit.

Dr. M. Price: I thank Dr. Mattison heartily for his paper, and especially so because I hope that it will stimulate others to investigate the effect of opium, not only upon the kidneys, but on other organs of the body. Patients operated on for some surgical trouble, often pass into a condition of their kidneys and a general condition in which opium is the chief factor, so that it is absolutely impossible to save them. This paper calls attention to the dangerous and destructive effect of the drug. What must be the effect upon a patient who has had a serious surgical operation? It causes a damming up of the secretions, irritating and inflaming the kidneys at a time when the stimulation of ether probably assists markedly in bringing about this condition. What must be the additional percentage of deaths from this cause alone? I have no experience in the particular line to which Dr. Mattison calls attention, but I have seen numbers of patients in surgical cases who, I have not the slightest doubt, have died from the opium treatment continued for a week or ten days. Not chronic opium-takers, but chronic opium-givers, men who batten-down their patients, covering up the dangerous condition. What must be the effect in these cases when, as has been pointed out in these other cases, patients are dying from kidney trouble produced by opium? I hope that the paper will teach some of us to leave opium alone.

Dr. John Aulde: I have been very much interested in the paper just read, but I would have been more benefited had the reader given us the advantage of his views in regard to the method to be pursued in the treatment of those cases where the kidneys have been damaged by the hypodermic use of morphine. I should like to have his opinion as to the advisability of using the hypodermic method in these cases, and whether or not the continuance of hypodermic medication will tend to perpetuate the disease which already exists. We know that when medicines are introduced into the system by the hypodermic method excretion takes place largely by the kidneys, a fact which has been demonstrated repeatedly with curare and other drugs, but when taken into the stomach, excretion is principally by the liver.

Dr. Mattison: Levinstein, whose experience has been much greater than my own, records a specific gravity of 1005. I have observed no case in which it was as low as this.

I am not prepared to answer the query of Dr. Cohen. My experience has not been sufficiently large to warrant any statement on this point. I, however, have a very firm conviction that the taking of morphine, especially subcutaneously, will induce decided renal change. There is a large proportion of the community, in every stratum of society, that is absolutely forced into taking the drug. They are forced to it by physical necessity. The larger number of cases that have come to me have been physicians. I have talked with these men closely, and I find that they have taken the drug simply to keep them up. The important point is this, that if the individual is under the necessity of taking the drug at all, my urgent advice is that the syringe be abandoned, and the drug taken by mouth.

In reply to Dr. Aulde, I would say that my own plan has been to at once abandon the syringe. I have done so, not because I thought the continuance of that method for a time would increase the damage, but because I believed that I attained a good effect when I broke the fascination of the syringe. I think that a moderate continuance subcutaneously, in cases requiring it, would not be necessarily injurious.

NEW YORK ACADEMY OF MEDICINE.

Section on Orthopædic Surgery.

Stated Meeting, November 21, 1890.

V. P. Gibney, M.D., Chairman.

DR. BEELY'S APPARATUS FOR MEASURING THE THORAX.

Dr. N. M. SHAFFER exhibited one of these instruments, which had been presented to him while he was in Berlin, by the inventor, Dr. Beely. A somewhat similar apparatus had been called, by Dr. Nebel, a *kyrtograph*. The apparatus consists of a series of narrow, parallel, steel bars, placed closely together, and sliding in a rectangular metal frame. Each bar terminates in a blunt point, near the end of which, on the under surface, is a metallic point, or stylus. This arrangement of bars looks not unlike a huge comb. On bringing the pointed ends against the chest, or any similar object having an irregular outline, the bars adjust themselves in the frame, so that the pointed ends form an outline identical with that of the object against which they were placed. A simple cam movement then clamps them in this position. The instrument is next laid upon a piece of paper resting on a sheet of felt, and the points on the under surfaces of the bars are made to puncture the paper by passing a small roller over all the bars successively. In this way, the desired outline is recorded on paper as a series of small punctures, about one-fifth of an inch apart. When taking a tracing from a patient while standing, an erect position is secured by means of a plumb-line fastened to a belt, which is buckled around the body. In order to secure still greater accuracy, the instrument is provided with a spirit-level. The exact level at which this transverse tracing of the chest is taken may be marked with nitrate of silver, so that tracings taken

at different times may be readily compared. With the patient in the prone position, the instrument may be used; but a longitudinal tracing, as of the spinal column, with the patient erect, is not within the contemplated scope of the instrument.

Dr. Shaffer said that he had made several tracings with this instrument, and he has been very favorably impressed with its action and accuracy.

Dr. John Ridlon said that he had seen Dr. Beely using it with the patient in the prone position, and that he had understood that its action was only satisfactory when employed in this way. At the Berlin Congress, Dr. Nebel had exhibited a much cheaper, but less accurately made instrument, constructed on the same principle. A series of round rods were placed parallel to each other, and made to slide through a large, round bar. The small bars terminated in buttons, which were applied to the chest. The outline was then transferred to paper by laying the machine on the paper and passing a pencil along the buttons.

Dr. A. B. Judson admired the mechanical features of the instrument, but thought that such tracings of cases of lateral curvature were of but little value, in view of the fact that the changes in contour occurred from day to day, as a result of differences in the general tone of the patient.

A CASE OF SUPPOSED EVACUATION OF A PSOAS OR LUMBAR ABSCESS THROUGH THE VAGINA.

Dr. Samuel Ketch presented such a case. A child, five and three-quarter years of age, of healthy parentage, and having a good family history, was admitted to the hospital on October 22, 1890, with the history of a fall six or eight weeks prior to her admission. Two weeks before she was presented for examination, she was first noticed to walk peculiarly, and she complained of "pain in her feet." She was thought to be suffering from hip joint disease by her attending physician. At the time of the examination, her general condition was fair, and there was no pain, and the motions at the hip joint were normal with the exception of a slight limitation of extension on the right side, when the patient was in the prone position. Close examination revealed a small kyphos in the lower lumbar region; the right hip was prominent, and relatively larger, and there was a feeling of fluctuation on that side. There was a discharge of pus from the vagina. The case was of interest, both on account of the unusual mode of evacuation of the pus, and because of the symptoms which had led to the diagnosis of hip joint disease.

Dr. Shaffer had seen the case just reported. He had met with cases where the abscesses of Pott's disease opened into the rectum, vagina, and bladder; and in one case of disease in the dorso-lumbar region, which had extended over a period of about twenty years, pus was discharged from the bladder at intervals of a few months, accompanied by the usual symptoms of acute abscess formation. The cases in which the abscess had opened in these unusual situations, had all done well, and he attributed this to the valvular opening through which the pus was discharged. In one of his cases, an abscess was found pointing into the rectum, and was purposely evacuated at this point by means of a trocar. The result had been extremely satisfactory. A similarly favorable prognosis could not be given where abscesses ruptured into the lungs. He had seen several of these cases, and in one, now under observation, which he considered unique, a boy with mid-dorsal disease, suffered at intervals from fever, accompanied by the expectoration of pieces of the cancellous portion of bone.

Dr. R. H. Sayre said that anatomical considerations would lead one to expect that owing to better drainage, abscesses opening into the alimentary canal would pursue a more favorable course than those which ruptured into the lung. He recalled a case where an abscess, situated on each side of the vertebrae, suddenly enlarged, and caused fatal asphyxia. The autopsy showed that "a saddle bag" abscess was situated at the bifurcation of the trachea.

Dr. J. K. Young of Philadelphia, said that he had recently seen a case of lumbar Pott's disease, in which the abscess had been evacuated through the vagina, and also through the abdominal walls. It had pursued a favorable course.

Dr. Thomas H. Manley had once treated a case of abscess in the mid-dorsal region, where evacuation had occurred through the umbilicus. It made a good recovery.

Dr. Agramonté suggested that the exact condition present in Dr. Ketch's case could not be affirmed until the vaginal discharge had been examined for gonococci.

The Chairman thought that such an examination was highly important, and suggested that search should also be made for the opening through which the pus was discharged.

Dr. Ketch, in closing the discussion, said that he was aware that the report of the case was somewhat premature, and had only been presented at the request of the Chairman for clinical material. He had not been able, as yet, to make the examinations suggested; but the rational symptoms, and the clinical history of the case seemed to warrant the position which he had taken. In an experience of thirteen years at the Orthopædic Dispensary, he had never before met with such a case, and had only seen one case in private practice; and in this one, Dr. L. A. Sayre had verified the condition. In this case there was a favorable termination.

An efficient wash for the nose and pharynx to be used by the patient at home should have the following characteristics:

1. It should be alkaline.
2. Its specific gravity should be a little less than 1,027, or about that of blood serum.
3. The temperature of the wash when used should not be below 100° Fahrenheit.
4. It should be of an agreeable odor, taste, and appearance.
5. It should be antiseptic.
6. It should be so medicated as to be appropriate to the condition of the mucous membrane of the nose and pharynx of the patient for whom it is prescribed.

The wash should be somewhat alkaline from the fact that alkalies have the power of dissolving mucus; and if a nose-wash is rendered somewhat alkaline by adding to it an alkaline sodium salt, we are simply following out the plan of nature, which, as already explained, pours into the nose from the blood-vessels of the mucous membrane a large amount of serum, which is alkaline from the sodium salts that it contains, and whose function is not only to moisten the inspired air, but also to render the secretions of the mucous glands more fluid. It is the presence of these salts that renders the watery discharges of the nose irritating when they are constantly flowing from the nostrils and drying upon the skin, so that they frequently produce eczema of the upper lip and alæ.

—Gleason, *Medical Bulletin.*

The Polyclinic.

PENNSYLVANIA HOSPITAL.

IN overcoming shock the blood should be kept in body as much as possible. This can be accomplished by bandaging and elevating the lower extremities. Hypodermic injections of atropine ($\frac{1}{150}$ grain) and morphine ($\frac{1}{8}$ grain) should be given to prevent the excessive perspiration that accompanies shock.—*Morton.*

The reports you occasionally hear of the inefficacy of antiseptic solutions in preventing suppuration, I believe can be attributed to the use of too weak solutions. This applies especially to the "bichloride solution." I never use it weaker than 1 to 1,000, and in some cases I use it as strong as 1 to 500; and I use it in almost every operation, excepting in abdominal operations.—*Morton.*

[The doctor knows whereof he speaks. Of the great number of operations he has performed within the last four months not one has ended fatally, and but a very few have been followed by suppuration, they being cases that were allowed to slough before entering hospital.]

For a case of sciatica occurring in a young man, Meigs prescribed 5 grains, increased to 10 grains, of potassium iodide, t. i. d. In the course of the nerve he ordered injections of a solution of morphine ($\frac{1}{6}$ grain) and atropine ($\frac{1}{120}$ grain) once or twice a day. These injections, he said, not only relieve pain, but have a decided curative effect. He enjoined absolute rest in bed.

The under surface of the tongue has a yellow color in jaundice, which should always be looked at for aid in diagnosing jaundice in colored people. There is a kind of dirty coloration in the conjunctivæ of colored people that makes unreliable as a witness of the deposition of bile pigment.—*Meigs.*

Catarrh of the gastro-intestinal tract is a frequent sequence of typhoid fever, constipation and a furred tongue being marked symptoms. To remedy this condition give large doses of the subnitrate of bismuth, for its soothing effect on the irritated mucous membrane. Diminish your dose as the pain and indigestion disappears. Enjoin a non-irritating diet. The bismuth acts in these cases as does paregoric in the constipation attending severe colic, which produces purgation by relieving the muscular spasm of the intestines.—*Longstreth.*

MEDICO-CHIRURGICAL HOSPITAL.

PROLAPSE OF THE UTERUS.

IN reducing a complete prolapse of the uterus, pass the sound into the uterine cavity to guide the uterus, while reduction is being made. The sound will prevent the uterus from becoming retroverted from its own weight, and, finally, retroflexed from intra-abdominal pressure. In effecting a reduction from the second to the first degree of prolapse, the uterus, perhaps, can be best elevated by the use of sponges attached to sponge-holders.

Recumbency, hot astringent injections, the ring pessory, the medicated tampon, and the T bandage will accomplish as good results as any of the well-known appliances in retaining the uterus in its position, unless the prolapse is consequent upon a badly ruptured perineum, which, of course, should be repaired. When prolapse of the uterus has become complete through perineal rupture, the organ can best be held in its position by means of a uterine supporter, with its abdominal and perineal bands. The abdomino vaginal supporter will hold the uterus at its proper elevation; but its fixed position on the outside of the vagina renders it incapable of yielding to the natural mobility of the uterus, and consequently it becomes painful, and contributes, at the same time, to the retroversion of the organ and its final retroflexion.—*Godfrey.*

PATHOLOGICAL ANTEFLEXION OF THE UTERUS.

Dysmenorrhœa affords the best evidence of the existence of pathological anteflexion of the uterus in imparous subjects. Its degree and duration determine the necessity for operative measures for relief, which consist in dilating the cervical canal and in straightening the uterine curvature. In dilating the canal with bladed dilators; in straightening the uterine curvature with the repositor or sound, and in retaining the uterus in its position with the stem pessary, all of the antiseptic care governing a surgical operation is required, and, in fact, this method of treatment should be looked upon in the light of a surgical operation.

The introduction of the stem pessary, for diminishing the uterine curvature, requires the close attention, and its removal is indicated upon the first appearance of irritation or pain. Unless the operative treatment is contra-indicated by cellulitis, as shown by undue tenderness in the anterior and posterior fornices, or by firm adhesions, its employment will generally give prolonged if not permanent relief.—*Godfrey.*

CHRONIC CERVICAL ENDOMETRITIS.

Caustic applications to the external os or to the lining of the cervical canal should not be used in the treatment of chronic cervical endometritis, for the reason that the resulting scar may implicate nerve filaments and induce neuralgia and reflex nervous derangements, or diminish, by contraction the caliber of the canal, and give rise to dysmenorrhœa. The application of two parts of tincture of iodine to one of carbolic acid will give good results.—*Godfrey.*

In acute bronchitis, to allay the distressing cough, soothe the mucous membrane, and to soften the phlegm, that it may be easily removed, give the following:

℞.—Morphinæ acetatis..... gr. $\frac{1}{20}$
Potassii " ..... gr. xx.
M.—S. A single dose.

—*Waugh.*

To maintain the integrity of the heart muscle when there is evidence of its failing, iron is the agent *par excellence.* It acts better in some cases by alternating it with strychnine.—*Anders.*

Always examine the urine for albumen before operating for cataract. If albumen be present when you operate, the edges of the wound may slough.—*Keyser.*

In the treatment of a case of infantile eczema (pustular), Shoemaker ordered a restricted diet, prohibited use of solids and all irritating substances. To clean out the intestinal track he prescribed calomel in 1 grain doses, to be taken once or twice a week, followed each time by a saline purgative, and to be continued for two or three weeks. Pepsin and bismuth, suspended in ʒss of glycerine, was ordered to be taken after meals. The integument to be bathed in

sweet oil until the incrustation was removed. Then the following is to be applied:

℞.—Sulphur subl..... ℥j.
Camphoræ..... gr. x.
Ol. anthemidis..... gtt. j.
Creasoti..... gtt. v.
Ung. aq. rosæ..... ℥ss.
" zinci ox. benzoat..... ℥j.
M.—Ft. ung.

After the child will have been under treatment until the eruption has been removed, the integument will have an erythematous appearance. To restore its natural hue the following will be given:

℞.—Sulphur subl..... gr. j.
Ext. malt fl..... f℥j.
M.—S. One dose. Repeat thrice daily.

This young lady (colored) comes before us complaining of a troublesome cough, which she has had for three months, causing her much loss of sleep. She does not remember of ever having fever or night sweats, but she feels very weak. Percussing her chest a clear, resonant note is elicited from the supraclavicular region, which, you know, is a favorable sign. Auscultation reveals a rhoncus in the large bronchial tubes, and moist, bubbling mucous rales. Sometimes a loud rhonchus like this masks the finer crepitant and sub-crepitant rales of the smaller tubes. In such cases we have to note the respiration, which is rapid when the smaller tubes are involved. Let us count her respirations—they number 22, which is not abnormal, allowing for the excitement of being before you. The fact of the rhonchus being heard on both sides is another favorable sign; whereas, if it were due to tubercular deposit, it would most likely be heard on but one side. We are more afraid of unilateral than bilateral abnormal sounds. The finer sounds (such as crepitant rales) are also more grave in their significance than the louder sounds (such as rhonchi). We have, then, before us a case, quite favorable in prognosis, yet will not admit of a spontaneous cure. There is a weakness in the constitution of this girl that will have to be remedied before her health can be restored. To secure this end, and repair whatever damage there may have been done to the lung tissue, there is no better agent than cod-liver oil, which we will give to our patient in this combination:

℞.—Ol. morrhuæ..... f℥iv.
Ol. eucalypti..... gtt. xx.
M.—S. Dessertspoonful t. i. d.

A little (2½ grains) of Dover's powder may be given at night, to allay cough. Stimulating applications to the chest will be of service. As a rule it is not advisable to give opium in diseases of microbic origin, for it has been found that it intensifies the activity of the microbe. Phthisical patients, who have been given repeated doses of opium, to allay cough, have suffered from an increase in the progress of the disease.—*Anders.*

In a case of incipient tuberculosis Anders prescribed the following:

℞.—Creasoti..... ♏i.
Syr. pruni Virg..... f℥j.
Elix. simp.....q. s. ad. ℥ij.
M.—S. One dose. Repeat four times daily.

When there is a troublesome cough without expectoration, he advises the addition of a sedative, such as the deodorized tinct. of opium, to the above. To arrest excessive tissue change he recommended the syrup of the hypophosphites of sodium and calcium. Regarding hygienic measures he said: "Try to disabuse your patient of the fear of 'catching cold' in going out. Caution him against wrapping himself with an undue amount of clothing. He should take moderate, but persistent outdoor exercise, and always wear woolens next to the skin. Let him eat that for which his appetite craves, provided it agrees with him."

Antisepsis is but a stepping stone to asepsis. In the use of the various antiseptic solutions you practically admit that you have allowed germs to get into the wound. Better to have *everything* aseptic before you begin an operation, then antiseptic solutions will be unnecessary.—*Laplace.*

In a case of gastric ulcer, in a female patient, Waugh advised the use of peptonized milk. As to medication he said: "In these cases the Germans give alkalies. They will do in plethoric people. In this case, however, iron is indicated. The constipation she complains of must be relieved by a laxative or an enema. To relieve the severe gastric pains small doses of morphine will be given, for its action as a local anesthetic. Silver nitrate, in one-fourth grain-doses every four hours, is a valuable agent. It forms an albuminate of silver over the raw surface of the ulcer, which compound acts as a protecting film to the exposed ends of the nerves in the ulcerated area, and in so doing allays irritation. It should be continued for four or five days, and given on a clean stomach, which can be made so by drinking a cupful of hot water. After exhibiting the silver salt for the time just stated, the stomach will be able to bear the iron salts. This plan of treatment, however, would not be indicated in the amenorrhagic form of the disease, in which the ulceration is due to a vicarious gastric hemorrhage. In those cases we would have to resort to such remedial and operative measures as would bring about a return of the blood to its proper channels."

Patient, male, aged sixty-eight, suffering from emphysema and nocturnal attacks of asthma, reported himself at Prof. Anders' clinic as practically cured. Two months ago he was placed upon the following treatment: Tr. ferri chlor., gtt. xv, t. i. d., to arrest degeneration of air vesicles; tinct. lobelia, gtt. x, every fifteen or thirty minutes, until paroxysm was relieved; potassium iodide, gr. v-x, t. i. d., for its action in relieving the capillary bronchitis arising from the passive congestion attending emphysema of the lungs. Auscultation of the patient's chest showed the lungs to be in a comparatively healthy state; no rales were heard, breathing was nearly normal, expiration being but slightly prolonged.

In removing a cataractous lens be sure that the fundus of the eye is normal. A diseased fundus would render the operation useless.—*Keyser.*

PHILADELPHIA HOSPITAL.

ACUTE TONSILLITIS AND PHAGEDENIC CHANCROID.

A MALE, aged twenty-two, of good physique, admitted to the venereal wards of Philadelphia Hospital suffering with chancroids, which had destroyed the greater part of the prepuce and attacked the glans. He was put to bed and the following lotion applied:

℞.—Ferri et potassæ tartratis..... gr. x.
Aquæ..... f℥j.
M.—Fiat sol.
Sig. Wash parts every three hours.

Internally:

℞.—Ferri et potassæ tartratis..... ʒij.
Syrup zingiberis..... ..... fʒj.
Aquæ bullientis..... fʒv.
M.—Fiat sol.
Sig. fʒij t. d.

Under this treatment he rapidly improved. About the sixth day after admission he complained of tenderness and swelling in his throat. Upon examination he was found to be suffering with acute tonsillitis. His temperature was 105.2, with severe rigors. The pus was at once evacuated, and he made a good recovery in a few days. The tinct. guaiac ammon. was given early as abortifacient without success, though it gave marked relief later. Dose, fʒj in milk as a gargle.
—*S. T. B.*

A convenient treatment for scabies, when it involves the body, is by means of the sulphur vapor bath. The patient is placed in a chair, and carefully surrounded with a double blanket, interposing a layer of cotton around the neck. About ʒij or ʒiij of sulphur sub. is placed upon a piece of tin and lit. The blanket must be as near air tight as possible on account of the fumes. In one case in which this was tried, where the whole trunk was involved, this method resulted in great improvement, and the case is now progressing to a cure.—*S. T. B.*

Dr. B. C. Hirst, in speaking of the various means used for overcoming the condition of sub-involution of the uterus, gave the following as the best combination to use:

℞.—Strychninæ sulphatis..... gr. $\frac{1}{20}$.
Quininæ sulphatis..... gr. ij.
Extracti ergotæ..... gr. j.
M.—Ft. pil. No. 1. S. At one dose.

INGUINAL HERNIA COMPLICATED BY HYDROCELE.

Here is a large mass that involves this man's scrotum, and, as you can see, it is as large as the man's head. When I grasp the tumor above, I feel a mass in my hand, and with little effort, I am able to reduce it into the abdomen. It is a direct inguinal hernia. When reduced there is still a large tumor that is translucent, distinctly sacculated and is an enormous hydrocele. I show you this case to impress upon you how large a tumor of this kind may become and the importance of a proper diagnosis. As this man is so far advanced in years it would not be well to resort to the radical means for a cure. The method that I use in treating *recent cases* of hydrocele is to draw off every drop of fluid with an aspirator and inject *pure carbolic acid.* Do not use the ordinary form of the acid, but take the pure crystals and dissolve them. The pure acid will sear the surface of the sack, will not be very painful, and will not be followed by slough, as will often be the case with the impure, weak acid. I do not use injections of iodine.

In old cases where the sack is thick, it is better to operate for the obliteration and removal of the sack.
—*Hearn.*

TWO CASES OF NERVE STRETCHING.

During the clinic hour of Dr. Hearn, Dr. Parker operated on a case for the purpose of stretching the sciatic nerve. Just how or why the process of nerve stretching accomplished relief in sciatica the doctor would not say—we do not know. In order to expose the sciatic nerve, a point was selected mid-way between the greater trochanter of the femur and the tuberosity of the ischium, at the lower border of the gluteus maximus muscle, and an incision carried from it down the posterior part of the thigh for four or six inches. The nerve is found behind the tendon of the bicepts muscle of the leg. After the nerve is found it is first drawn well down; then drawn upward with force sufficient to lift the leg. The sciatic nerve is capable of resisting a force of one hundred and eighty pounds before it will rupture. Every antiseptic precaution must be taken in the operation and the wound dressed antiseptically, and absolute rest in bed until union has taken place. Another point to be observed is to examine the nerve for a high bifurcation, so that both parts may be properly stretched. A Bohemian doctor demonstrated on the cadaver that the spinal cord was stretched by traction on the sciatic nerve, but whether this would be the case in the living subject is still in doubt. One thing is certain, and that is that the operation seems to affect the nutrition of the nerve, and often results in a cure. Dr. Hearn then operated on the other case in the same manner.

Dr. Charles K. Mills has just finished a very interesting and instructive series of lectures on nervous diseases before the students. As the hospital is amply supplied with a large variety of nervous cases, it is needless to remark that the doctor did not fail to avail himself of the best and most instructive cases.

In orchitis and acute hydrocele Horwitz advised multiple punctures to relieve tension of the effusion; strapping; applications of the ointment of iodoform and belladonna in nervous patients. Internally he prescribes the following mixture:

℞.—Tr. aconiti..... ♏j.
Morphinæ sulph..... gr. $\frac{1}{4}$.
Antimonii tart..... gr. $\frac{1}{15}$.
Magnesii sulph..... gr. xij.
M.—S. One dose. Repeat thrice daily.

If a man has heart disease, he should avoid high altitudes, for with the diminution of the external or atmospheric pressure, there is a corresponding increase in the cardiac activity. Hence, phthisical patients, with heart complications, should not be lured to the lofty resorts of valetudinarians. A pure, dry atmosphere at a low altitude is best suited for them. Nervous patients should not be sent to high altitudes. Their sleep is disturbed, and they become much excited, quickly passing into a state of nervous prostration.—*Curtis.*

Isaac Hamilton, a prominent farmer near Marshall, Mo., died, recently, of typhoid fever. His wife and daughter, it is alleged, believe in the doctrine of "Christian science," and for three weeks before his death the patient had no medicine or medical treatment. The Coroner returned a verdict to the effect that the deceased came to his death by the criminal neglect of those who had him in charge after medical treatment had been abandoned.

Dr. Benjamin, of Camden, N. J., gives the following for puerperal convulsions:

℞.—Pot. brom..... ʒiij.
Pot. iod..... gr. x.
Syr. tolu.,
Aquæ..... āā ʒij.
M.—Sig. Tablespoonful before dinner, supper, and at bedtime.

This was given about one week, when, to my satisfaction, all symptoms had disappeared. I was especially impressed with the rapid disappearance of albumen from the urine.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

"Whom the gods would destroy they first make mad."

IF the present management of the *Journal of the American Medical Association* is bent on its own destruction, it can be accomplished in no speedier manner than by inducing its friends to continue attacks such as have been made in the *North American Practitioner* in its last issue; the editor of which, as is well known, has been a leader writer under the present management of the *Journal* of the Association. It is certainly a breach of good taste to criticise a predecessor. We know of no journal in the world in which such a course has been pursued, and it would appear to an outsider that there are some things that had better not be spoken, and it is best to avoid saying things in the heat of discussion one might be sorry for afterwards. We do not desire to criticise the present editor of the *Journal* of the Association, his leader writers, or his method of conduct of the *Journal*, but if personal matters must be introduced into the discussion of a subject in which the individual members of an association are alone concerned, the issue can be met, and it probably will not be shirked by those directly concerned.

The question of the permanent place of publication of the *Journal* is one that should be discussed fairly, fully, and freely, on its merits; and it is simply begging the question for the opponents or the advocates of removal to go into a discussion of whether if the *Journal* is moved, or if the *Journal* is not moved, who will conduct its editorial columns. The question of the editorship is a question which the trustees of the *Journal*, elected by the suffrages of their fellow-members, are amply able to settle; and while personal warfare may be extremely entertaining for those who imagine that they are not concerned in it, it is seldom profitable, and not infrequently it proves a veritable boomerang. *Verbum sap.*

A WINTER CITY.

IN choosing a winter resort for invalids, the most important points to be considered are: climate, sanatory state, accommodations, accessibility, means of diversion, and cost. In the last few years Atlantic City has become so popular as a winter resort, that a consideration of its claims may not be out of place.

Seaside towns in general have a great advantage over those situated inland, in that they are not so cold in winter. Atlantic City appears to be specially favored in this respect; its mean winter temperature being several degrees higher than that of any other point on the Jersey coast. Rain runs quickly off the gravelly streets and soaks into the sandy soil, so that almost as soon as the rain ceases, one may walk out without overshoes. Malaria, formerly prevalent, has completely disappeared since the fresh-water ponds were filled up. The system of drainage now in operation is efficient; the sewage being drawn off to the works in the meadows, where it is disinfected, burnt, or converted into fertilizer. All wells are connected with this sewer system, or the owners are compelled to have them walled up and cemented, so that sewage is no longer allowed to percolate into the sandy soil, as of old. Before the present system of drainage went into operation, the soil of the island became pretty well saturated with sewage by the end of the summer season, although this was rapidly disinfected and carried off by the rise and fall of the tides. This probably gave rise to some sickness; and it may not be known to all our readers that Atlantic City now enjoys a thoroughly efficient system of drainage. The single objection to the present system is that no provision is made for carrying off surface water from the streets, etc. There are few, if any, cities with which this objection has as little weight as with Atlantic; as the soil so quickly absorbs water, and the number of animals to contribute street-dirt is very small; while even in the summer the streets appear remarkably clean to a Philadelphian.

Seaside resorts must be as far above suspicion as Cæsar's wife; and good sanitation is essential to their existence. Cities which live upon the favor of health-seekers cannot afford to neglect anything which tends to the comfort and well-being of their visitors; and the enormous amounts of money invested in Atlantic City are the best of reasons for insuring good sanitation and police. The citizens are fully aware that any serious deficiency in these respects would render ten millions of dollars unproductive, and even sweep these valuations out of existence. No other seaside resort has as much at stake as Atlantic City; and consequently no other offers as valuable a guarantee to the visitor.

The water supply is pure and abundant. The city water is brought from the main land, from a district where there are neither inhabitants nor factories

to pollute the streams. Besides this, several artesian wells have been sunk, which afford a supply of pure water.

A large number of hotels and numerous smaller houses now remain open during the winter, and the visitor has abundant choice in this respect. There are houses where the high tides come almost into the parlors, and others situated a few squares back from the ocean; so that those who love to fall asleep with the roar of the ocean in their ears, and those to whom this would be unpleasant, can both be suited. The increasing tendency to resort to Atlantic City in winter has caused the general raising of the houses above the ground, on brick foundations; and has resulted in many changes in the arrangements for heating. Even in the coldest northeast storms, the winter houses are comfortable. Nervous invalids often find isolated buildings, like those at Cape May Point, very unpleasant in rough weather; the loneliness and the exposure to high winds causing a feeling of insecurity. This is altogether absent in the Atlantic City hotels in the built-up district.

In the matter of accessibility, no other resort can equal Atlantic City. Three railroads bring it within an hour and a half's ride of Philadelphia, and allow of that easy communication with friends and doctor which adds so much to the invalid's comfort. From New York and Baltimore the distance is not great; in fact, the journey is nothing as compared to a trip to Florida, or even to Fortress Monroe.

It has been our experience in hospitals that patients never like the secluded portions of the building, but prefer rooms where there is life and movement, at the risk of no matter how much noise. If this be so with the sick, it is much more so with the invalid. The winter population of Atlantic City is large enough to allow a fair share of amusements; the electric railway renders every part of this island accessible, and there is always something of interest to occupy the time of those who are well enough to go about.

The cost of living at Atlantic City in cottages or at the hotels is about the same as at other resorts. Boarding can be had at from $10.00 to $25.00 per week. A seven bed-room cottage can be rented during the fall, winter and spring, for $30.00 to $50.00 per month.

The greatest deficiency of Atlantic City is the lack of suitable accommodations for very sick people. It does not require much argument to show that this class requires something very different from those who are comparatively well. The association of the two classes in the same building interferes with the proper catering to either. Illness that requires nursing and special diet is very expensive at a hotel, and even then the discomfort is great. For these reasons we hope that the day is not far distant when Atlantic City will provide for this class of her patrons; and that her claims will then be recognized as the most desirable winter resort north of Florida.

Annotations.

PREVENTION OF SCARLET FEVER AND DIPHTHERIA.

WE print herewith a full text of an act to prevent the spread of scarlet fever and diphtheria in the District of Columbia, which has just been passed by Congress. The passage of this act has been due to the energy and vigilance of Dr. John B. Hamilton, Surgeon-General of the Marine Hospital, a man who makes his own every interest for the furtherance of measures for public health and sanitation. All praise to such men!

AN ACT TO PREVENT THE SPREAD OF SCARLET FEVER AND DIPHTHERIA IN THE DISTRICT OF COLUMBIA.

SECTION 1. *Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled*, That from and after the passage of this act it shall be the duty of every registered practising physician or other person prescribing for the sick in the District of Columbia to make report to the health officer, on forms to be furnished by that officer, immediately after such practitioner becomes aware of the existence of any case of scarlet fever or diphtheria in his charge; and in case such person shall fail to so report within twenty-four hours he shall be subject to a penalty of not less than five nor more than fifty dollars, and in case of a second offense the penalty shall not be less than ten nor more than one hundred dollars. In case no physician shall be in charge of such patient the householder where such case occurred, or person in charge thereof, the parent, guardian, nurse, or other person in attendance upon the sick person knowing the character of the disease, shall make the report above mentioned, and in case of failure to report shall suffer the same penalties as provided for physicians in this act.

SEC. 2. That it shall be the duty of the health officer cooperating with the attending physician to cause a suitable placard, flag, or warning sign to be displayed from the front of the premises or apartment where any one case of scarlet fever or diphtheria is present. It shall be unlawful for any person to remove such placard, sign, or warning flag, when so placed, without permission of the health officer, and it shall be the duty of the said health officer, in conjunction with the attending physician, to cause the premises to be properly disinfected, and to issue the necessary instructions for the isolation of the patient.

SEC. 3. That no person shall visit or attend any public or private school, or place of public assemblage, or appear on the public streets or in the parks while affected with scarlet fever or diphtheria, and any adult person, parent, or guardian of a minor convicted of having knowingly violated the provisions of this act shall, upon conviction, forfeit and pay a sum not less than five nor more than fifty dollars; and it shall be the duty of physicians, while in attendance upon cases of scarlet fever or diphtheria, to exercise such reasonable precautions to prevent the spread of the said diseases as may be prescribed by the health officer of the District of Columbia in regulations.

SEC. 4. That no person who has convalesced from diphtheria or scarlet fever shall be allowed to attend any public or private school, seminary, or college until the attending physician shall have furnished a certificate that said patient has completely recovered, and that there is no danger of infection to other persons. All persons who shall, after convalescing from diphtheria or scarlet fever, visit schools, seminaries, or colleges, without providing themselves with such certificates, shall suffer the penalties provided for in section one of this act.

SEC. 5. That the provisions of this act shall apply to every ship, vessel, steamer, boat, or craft lying or being in the rivers, harbors, or other waters within the jurisdiction of said District, and to every tent, van, shed, hovel, barn, outhouse, cabin, or other like place, as if the same were an ordinary dwelling.

SEC. 6. That the word "regulations," as herein used, shall be held to mean also rules, orders, and amendments. The words "person in charge thereof" shall be held to mean the owner, his agent or factor; the tenant, his clerk or representative; the nurse, or any one or more persons who by reason of their position are charged with the management or care of the premises, or interested in the person afflicted. The words "practitioner of medicine," or "practitioner,"

shall be held to include all persons who undertake to treat persons afflicted, either gratuitously or for pay.

SEC. 7. That any person who shall knowingly make, sign, or deliver any false report or certificate herein provided for, upon conviction thereof in the police court of said District, shall be fined not less than five nor more than fifty dollars, and, in default of payment thereof, be committed to jail for not less than one nor more than twenty days.

SEC. 8. That the expenses necessarily incurred in the execution of the provisions of this act shall be borne from the general appropriation for the maintenance of the health department of the District of Columbia, and the jurisdiction of civil and criminal procedure in the enforcement of this act is hereby vested in the police court of the said District, with the same right of appeal as in other civil and criminal trials in said District.

THE CHIGGER.

DR. H. M. WHELPLEY, F.R.M.S., has issued on a single sheet an interesting paper on the Chigger insect (leptus irritans), being the continuation of a paper read before the St. Louis Microscopical Society, and published in the *Popular Science Monthly* for last February. This human parasite is found in the Eastern and Southern States, as well as throughout the Mississippi valley. It also attacks horseflies and is said to be very troublesome to young chickens. It will be associated in the minds of most people with the blackberry vine, and all who delight in berrying will recall the ravages on their flesh and temper which this little "tick" has made.

A NEW CURE.

A PARISH priest in Bavaria has devised a new "cure," which the patronage of a Rothschild bids fair to render fashionable. The priest's idea is to increase the resisting power of the skin; for which purpose he dresses his patients in coarse linen underclothes, plunges them into cold water, throws on the clothing without stopping to dry the skin, and runs them for as long a time as he considers wise. If snow can be found, they run through it barefoot; if not, through wet grass or cold water; for half an hour. This is followed by a brisk walk.

There are the elements of sound sense in this treatment; and it is worth while to note how much more of true piety there is in this priest's works than in the blasphemous stuff miscalled Christian science. One says: Mortify the flesh; restrain the lusts of the body, and by a pure life rid yourself of the disease brought about by indulgence in ease and pleasure. The other says: Don't bother yourself to do anything, but just tell God to come and pick you up. It's His business.

THE CENSUS OF 1890.

THE Superintendent of the Census Office issues a bulletin giving statistics and deductions concerning the recent enumeration of the population, from which we extract the following facts as likely to be of interest. The increase of population between 1870 and 1880 was 11,597,412, being a percentage of 30.08; increase from 1880 to 1890, 12,324,757, being a percentage of 24.57. It will thus be seen that while there is a small percentage of increase, the absolute increase for the decade just closed is 727,345 more than the increase during the previous decade.

The greatest increase has been in the Northern Central Division, including the States of Ohio, Indiana, Illinois (in which there has been a decrease), Iowa, Dakota, Nebraska, etc., and in the New England and Middle States. In single States, the increase has varied. The population of Dakota (North and South) has increased 277 per cent. Most of that increase being in the first five years of the decade; that of Nebraska, 134 per cent.; while the population of Washington State has increased from 75,116 to 349,516, being an increase of more than 365 per cent.

Of the Atlantic States, the greatest increase has been in New York, Pennsylvania, Massachusetts, and New Jersey, while in Maine, New Hampshire, and Vermont, the rate of increase between 1870 and 1880 has not been maintained.

In general, it may be concluded that those sections of the eastern part of the country in which manufactures have flourished have increased, while there has been a corresponding decrease in those Eastern States in which farming formerly constituted the principal industry; whereas the phenomenal increase in the population of the far West, and particularly of Dakota, has been due to the increased facilities for agriculture and grazing.

The census shows the present population to be 62,480,540.

HABITS OF DOCTORS.

DR. J. C. SESTON, of Rushville, Ind., writing in the *Indiana Medical Journal*, says: Let us take a view of the doctor and some of his habits. Sombody has said that the worst habit one can form is the habit of having regular habits. It is not necessary to add that he was not a physician, for there is no set of men, the world over, who acquire so quickly or cling so tenaciously to their habits. Whether the daily routine of cases is so similar, or our work presents such great diversities, or one has no work at all, it is strange, but nevertheless true, that from all these various standpoints we form habits of moving in the same ruts. It is claimed that the habit of attending church regularly is the hardest one to cultivate; this may or may not be true among most people, but with doctors the habit of keeping clear of forming habits is the hardest one to become our second nature.

Some treat the symptoms as they arise, regardless of cause. Such a physician is very likely to be smooth in his bearing, oily to the touch, and nurse his case as well as his patient. He will know all the words of learned length and thundering sound, is leisurely and self satisfied, dislikes innovations, and holds fast to that which has the merit of being old. In nearly every matter under the sun he would say: "Let nature take her course."

Then some have the habit of being loud-voiced and pompous, blustering and determined. His idea is to grapple with a disease and throw it. He looks upon the patient as a battle-ground, disease his natural enemy, and he goes at it with bare knuckles. His head is well developed about the mastoids, and he gives a medicine because it will do good. By nature and by habit he is a fighting man, and the worse his patient becomes the closer will he stick by him; and even after his patient has gone the way of all flesh, he still fights it out with the estate.

Did you ever see the doctor who looked wise; who had the habit of being grave and even grim; who was so deliberate that the act of taking out a watch and examining the pulse, was a procedure fraught with the most weighty importance? You know how careful he is of all the forms and ceremonies; now he will never offer an opinion until he gets yours. This is a habit which has grown clearly away from the affectation it resembles. This is the kind of doctor to travel—"on his shape."

Letters to the Editor.

FLORIDA ON WHEELS.

IN view of the series of sketches in reference to "The West Indies as a Sanitarium," which have appeared in THE TIMES AND REGISTER, some one of the enterprising newspapers or publishing firms in that latitude should take a few lessons from the State of Florida, for instance, and issue a Trade Edition similar to that of the *Times-Union*, Florida's representative daily, which is a marvel in the history of Florida journalism.

Besides, among other features contributing to keep Florida to the front, is the unique conception of concentrating as much as possible of the specialties in agriculture and mineral capability of the State inside of a railway car, sending it up and down the country, and has probably done Florida more good than any scheme yet tried. W.

ELECTRICITY IN GYNECOLOGY.

I ENDORSE Dr. Hutchinson's letter in last TIMES AND REGISTER—every word of it.

If Dr. Price expressed himself as reported, such an antiquated, fossilated, "back-number" expression of professional ignorance is amazing.

It takes a Job-like supply of the cardinal virtue to notice a statement of one who so little knows what he is talking about.

There are some things better unsaid—among them his assertion—for 'twould have been vastly more to his credit, and that of his profession, if, along *that* line, he had "kept silence." The writer works in a field special and unique—see Notes on New Remedies, October, 1890, copy furnished if desired—and his opinion, based on experience, of galvanism for the relief of neuralgic pain, is soon stated: It is the *Krupp-gun among anodynes.*

Dr. Price is behind the times—he surely is, and his presumption in thus arraying himself against some of the best attested clinical facts that have ever gone into history, is great. Let him attend a course in electro-therapeutics. J. B. MATTISON, M.D.

BROOKLYN, 314 STATE STREET.

ADULTERATED VINEGAR.

A FEW days ago I was invited to address the Great American Agricultural Union, at Burlington, New Jersey, and in course of the subsequent discussion, I learned that the great fruit-growing county of Burlington is so flooded with a spurious article, called "vinegar," sold at eight cents a gallon, that the farmers can find no sale for the genuine article, made from apples; and, in consequence, thousands of bushels of apples are permitted to rot under the trees.

As chairman of Committee on Nostrums, Proprietary Medicine and New Drugs, of the American Association for the Study and Cure of Inebriety, I have, for the past two years, been antagonizing dangerous patent medicines, especially those containing opium, alcohol, or other poison, and you have been kind enough to publish some of the results.

I wish now to call the attention of the profession especially to this spurious vinegar, threatening, if not already invading our city, and also to request physicians in every section to aid the committee in our warfare against this great and growing evil, by writing me any information relative to the fact, or injurious consequences of the traffic in fraudulent preparations for human consumption, whether as food, beverage, or medicine. N. ROE BRADNER, M.D.

WISSINOMING, PHILADELPHIA.

Book Notices.

A TEXT-BOOK OF PRACTICAL THERAPEUTICS; With Especial Reference to the Application of Remedial Measures to Disease, and Their Employment upon a Rational Basis. BY HOBART AMORY HARE, B.Sc., M.D. Octavo, pp. 632. Cloth, $3.75; leather, $4.75.

For students' uses, this work is rendered unfit by the absence of any sort of a classification of remedies; without which the task of learning therapy is well-nigh impossible. On every page are errors of grammar, rhetoric, and proving, that speak of either great carelessness or great haste in preparation. The studies upon the physiological action of drugs, that make Wood's magnificent work so valuable, are not to be found here. Nor is Bartholow's wealth of resource, nor his vivid expression. The newer remedies are described very briefly, but with excellent judgment; and in this particular the work is commendable. But the lack of clinical experience shows through every page. After reading the sections on diphtheria and typhoid fever, it is difficult to believe that the author ever could have attended a serious case of either. There are, however, ample evidences in the book of ability far above that of the closet physician, and in ten years from the present, Hare's Therapeutics may have grown into the standard text-book of the day.

TRANSACTIONS OF SOCIETIES.—We are in receipt of the Transactions of the Medical and Surgical Faculty of the State of Maryland, containg a report of the proceedings at its ninety-second annual session. Some of the subjects discussed follow: Some Practical Points on Hernia, by Dr. Robert W. Johnson; The Early Detection of Pulmonary Consumption, by Dr. William B. Canfield; Typhoid Fever: Its Prevention and Treatment, by Dr. Joseph T. Smith; A Review of Hypnotism, by Dr. George J. Preston; Persistent Headaches and How to Cure Them, by Dr. Julian J. Chisholm; also reports of the sections. All of the papers are able and well written, and reflect great credit on the society.

We have also received the Transactions of the American Otological Society, containing the papers read at the Twenty-third annual meeting held last July. Among the contributors the following well-known names appear: Drs. Charles H. Burnett and B. Alex. Randall, of Philadelphia; Drs. Albert H. Buck, Owen B. Pomeroy, and Huntington Richards, of New York; Dr. Samuel Theobald, of Baltimore; Dr. Charles A. Todd, of St. Louis; and Dr. Lucien Howe, of Buffalo.

SOME GOOD ADVICE ON PLEURAL FISSURE.—When it is believed that phthisis exists, it is better treatment to leave the pleura alone, if possible. It is not a bad thing to have compression of the lung in tubercular involvement, as it tends to limit the progress of the trouble and define its boundaries. Often, when the pleura is full of pus, it will force a fistulous opening into the lung, in which case one must be governed by the extent to which the cavity is emptied by expectoration. When it is discharging freely, the fistulous opening being low down, the lung expands more and more against this pyo-pneumo-thorax; then it is better, considerably, in the presence of tubercular trouble, to leave the condition of things as they stand. If the fistula is high up in the pleura, discharges will escape with less freedom, hence, here drainage should be established.—Pepper, *Med. Age.*

The Medical Digest.

FRENCH NOTES.

By A. E. Roussel, M.D.

Treatment of Frost Bite (M. Brocq).—

1. Bathe the hands in a decoction of walnut leaves; dry.
2. Friction with camphorated alcohol.
3. Powder with the following:

Salicylate of bismuth	150 grains.
Starch	1,350 "

4. To calm the itching, rub with

Glycerine,	
Rose water	āā 12 drachms.
Tannin	2 grains.

Then powder with No. 3.

5. If ulcerations exist, envelop with walnut leaves soaked in hot water.—*Revue de Thérapeutique.*

Non-Operative Treatment of Vaginismus. (Lutaud).—Before submitting patients suffering from vaginismus to operative treatment, which consists in the dilatation of the vaginal spincter during anesthesia, Lutard advises a trial of the following curative treatment:

Introduce into the vagina each night the following suppository:

Iodoform	15 grains.
Extract of belladonna	8 "
Cacao batter	150 "

For one suppository.

Inject three times daily one quart of hot water, to which is added one teaspoonful of carbonate of soda; then apply the following solution by means of a brush:

Chlorhydrate of cocaine	30 grains.
Distilled water	1 ounce.

This treatment should be continued for one month. Attempts at coitus should be practised every two or three days after having applied cold cream to the vulva and penis.

An accouchement very often causes a disappearance of the vaginismus. Lutaud recommends a hypodermic injection of ⅙ gr. of morphine before coitus. The sedative action of the morphine acting more especially on the genital system may permit coitus, and often results in pregnancy, and as a result the cure of the vaginismus.

—*Journal de Médicine de Paris.*

Solubility of Naphthol-β.—M. Charrin remarks that a saturated solution of boric acid in water increases the solubility of naphthol-β from 0.22 to 0.70 or 0.80. The temperature influences this solubility. The antiseptic power is increased, as demonstrated by experiments made by M. Charrin.

—*La Bulletin Médical.*

La Médecine Moderne informs us that physicians who desire to obtain Koch's lymph should write to Dr. A. Libbertz (Berlin, N. W. Luneburgerstrasse, 28 II.)

Le Bulletin Médical, in a well written article upon Koch's discovery, discusses the probabilities as to the nature of the remedy, and arrives at the same conclusion as ourselves, namely, that everything points to a sterilized culture fluid of the bacillus tuberculosus as the active agent.

Fink, in the *Indian Medical Gazette*, reports a case of enlarged spleen with ascites, successfully treated by the inunction of biniodide of mercury ointment, and tapping. Indian surgeons speak so highly of this treatment for splenic enlargement that it should be tried in our malarial districts.

An Efficient Tonic.—The old adage, "An ounce of prevention is worth a pound of cure," never fails to be on our lips, or to find an echo in our experience. For some time past physicians on both sides of the Atlantic have been in search of a remedy or a preventive for la grippe; and New York doctors, have according to the New York *Press*, given very strong testimony in favor of Reich's Tokayer Ausbruch as a tonic of great strength and purity. It has been found of special value in cases of debilitation, and it is believed that if it be applied to a run-down system, such an influenza as the grippe may be avoided. Lorenzo Reich, 334 Fifth avenue, New York City, is the importer.

Gangrenous Carbuncle.—In this case the carbuncle was very large, covering the whole of the back of the neck. All the tissues down to the spinous processes of five cervical vertebræ were gangrenous.

The most concentrated solution of sulphate of zinc and dilute sulphuric acid was applied over the carbuncle by means of absorbent cotton continuously, and injected into the sloughing mass also. The patient took the tincture of iron, quinine, and strychnine internally; also nitro-glycerine, one-hundredth of a grain every three hours, as there existed great general prostration.

The local and general treatment enabled the system to arrest the sloughing, to establish improved vital action, throw off the sloughs and heal the very large wound.—Brown, *Weekly Med. Review.*

Antipyrine.—While it is true that antipyrine is given for the purpose of subduing the fever of phthisis, we must not lose sight of the fact that it has a capital influence on this disease after the fever has subsided. Phthisis is undoubtedly a constitutional and not a local disease, depending ultimately on a depreciated nervous system, and it is in virtue of its selective affinity for the nervous system that antipyrine acts as an antipyretic, and, associated with other well-directed treatment, it yields the beneficial therapeutic influence in this as well as in all other nervous diseases. It should, therefore, be continued in smaller doses after the fever has gone. In conclusion, it must be added, that if it is given for a protracted period it produces a rash of the skin, which can, however, be obviated by alternating it with phenacetine.

—Mays, *Jour. Amer. Med. Assoc.*

Peroxide of Hydrogen as a Sterilizer of Milk.—Dr. Heidenhain (*Centralblatt f. Bakt, u. Parasitenk.*, Bd. viii, No. 16, October 8, 1890), referring to Dr. Altehoefer's researches on the use of peroxide of hydrogen in the disinfection of water, says that it may also be useful for sterilizing milk, although he is not able to say as yet how the digestibility of milk so treated will be affected. He finds that children take it readily, and that the peroxide, mixed in the proportion of five or six tablespoonfuls to one litre of milk, does not cause the milk to curdle or to become sour, even when it is left in a room at summer temperature for forty-eight hours, the slight acid reaction with litmus paper being due to the action of the disinfecting material and not to the production of lactic acid. The cream that rises is so sweet that butter cannot be made from it for a very considerable length of time. If further researches confirm these results

and are in other ways satisfactory, there is some hope that a long-felt want will be met. It will in any case be a great advance in the treatment and preservation of milk.—*British Med. Jour.*

Grafting the Thyroid for Myxœdema.—The operation of grafting the thyroid in a case of myxœdema has again been performed with success. The patient was shown by M. Merklen, at a recent meeting of the Société Médicale des Hôpitaux in Paris; the thyroid graft was taken from a living sheep at the time of the operation; no antiseptics were used, but the graft and wound were kept carefully aseptic. Healing occurred by first intention, and the patient, a woman, aged forty-one improved considerably. The improvement appeared to be due in great part to the arrest of metrostaxis, from which the patient had previously suffered for months at a time; the hemorrhage ceased three days after the operation, and had not recurred when the report was made three months later. The swelling of the face had decreased, the pseudo-lipomata diminished, and the mode of speaking became more natural. The graft, which consisted of one of the lobes of the gland, was inserted beneath the skin in the right submammary region.—*British Med. Jour.*

Treatment of Tonsillitis.—In an article in the *Indian Medical Gazette*, Hehir recommends pilocarpine in doses of $\frac{1}{8}$ grain every two hours, to reduce the tenacity of the secretion. The drug used in India is, perhaps, of poor quality, as such doses here produce much more than the "slight salivation" aimed at by Hehir.

He finds few cases benefited by aconite; rapid relief ensuing in only two cases out of seventeen, and both these were children. Locally he recommends steaming, and the application of cocaine in 6 per cent. solution, and of powdered guaiac resin. Internally he gives tartar emetic, in doses of grain $\frac{1}{16}$ every two hours; adding ammonia or strephanthus to combat depression if excessive. He also believes that port wine is of local value, as well as the best stimulant. Further, he advises concentrated, liquid food, the stereotyped initial mercurial purge, small incisions into the affected gland, and tepid, antiseptic gargles. By these means he reduces the duration of the attack to three days.

The *officiat*, or second grade of practitioners in France, has long been threatened, and appears now to be on the point of extinction. The Chamber of Deputies some time since appointed a committee to examine and report upon the subject, and the result of its deliberations is entirely in favor of suppressing the *officiat*. The report presented to the Chamber states that there is every reason to expect that the number of doctors of medicine that will graduate in future will be quite sufficient for the needs of the population, especially if more protection is afforded by the law against the encroachments of quack and of foreign practitioners. It is also pointed out that not only the great majority of medical men, but of the existing *officiers*, are in favor of the suppression of the lower grade. The number of candidates for it has of late decreased considerably, and since 1883 the course of study and the examinations have been raised to a level not very much inferior to those required for the doctorate. The report recommends that the existing *officiers* be admitted to the doctorate on passing two clinical examinations. It is greatly to be desired that the whole medical profession should possess the same diploma—viz., that of Doctor of Medicine—as is now (according to the committee) the case in Germany, Austria, Italy, Belgium, Holland, and Spain. Here the committee's information must be considerably at fault, for in Germany, Holland, and Spain practice is by no means confined to M.D.'s.—*Lancet.*

Cure of Gangrene.—I had a case of gangrene of the third finger which extended rapidly into the hand in spite of all I could do by following the directions of all authorities I have seen on the subject. The purplish color advanced steadily under the serous bleb, until it reached the middle of the metacarpal bone. In the palm this color was not perceptible, owing to the thickness of the skin, but it presented a peculiar tallowy color to a corresponding extent.

Believing that any further advance would entail a loss of part, if not the whole, of the hand, I felt justified in indulging in an experiment that seemed to me likely to succeed. I immersed the hand in alcohol, contained in a large pitcher suspended over the patient, as he lay in bed, elevating the hand to prevent swelling of the arm. The alcohol was kept warm by means of a coil of rubber tubing in the bottom of the pitcher, through which hot water was kept flowing.

The advance of the dreaded purple color was checked. The already gangrenous tissue assumed a hard, cooked appearance. I continued this plan of treatment for about sixty hours, when I replaced the alcohol by a boracic acid solution, kept hot by the same apparatus. This acted as a most efficient poultice, and in a short time the dead tissue was cast off, fortunately leaving enough live tissue next the bone to throw out granulations. In time the hand and finger made a perfect recovery.

—Allingham, *Canada Lancet.*

Umpfenbach adds something to our knowledge of *orexin hydrochloride*. Experiments made on himself showed that a single dose of four grains always produced a sensation of more than usual hunger, which as a rule lasted for some days. In two cases of anæmia, a convalescent from influenza, and a man with chronic gastric catarrh, the remedy was also successful, with one exception (an anæmic girl). These patients were all sane. Of the inmates of the asylum twenty-five took orexin for want of appetite, dependent on bodily (four cases) or mental diseases (twenty-one cases). Out of the four cases of the first-class three were benefited; of six hypochondriacal and hysterical patients the effect was produced in five; eleven cases had to be fed artificially through a stomach tube; eight grains of orexin given to these twice a day mixed with their soup. In five of these eleven, hunger was so stimulated that they took food themselves for some time; in one the effect was only transient, and in the five others absent. Of the four remaining cases of the second-class appetite was improved in only one. Suggestion was avoided as far as possible, and gentian was not combined with the orexin. Unpleasant after-effects were not observed. In conclusion, the author says that in orexin we have a really useful stomachic, though like all medicaments, it is not in every case completely successful. A similar conclusion was reached by Dr. Reichmann (Giessen), who gave it in thirty-six cases.

—*Prov. Med. Jour.*

Mosquera's Food Products—Beef Meal, Beef Cacao.—Parke, Davis & Co., whose reputation for original work has long been established, announce that after thorough study of the various food products

they can now supply preparations which will fulfil all the requirements for therapeutic and dietetic use.

They are now prepared to supply Mosquera's Food Products—Beef Meal and Beef Cacao—of which a careful chemical examination has been made, which has led to the following decisions having been arrived at:

Mosquera's Beef Meal is a perfectly pure predigested meat, containing all the nutritious constituents of good lean beef, half of which are in soluble form, ready for immediate assimilation, and the other half easily digestible by the gastric and pancreatic juices. Therefore the entire preparation, being practically dry, is composed of nutritive matter, containing about 40 per cent. of soluble peptone and albumose.

It represents, in actual nutritive value, at least six times its weight of good lean beef.

It is perfectly palatable, and will be tolerated with ease by the most delicate stomach.

It admits of being administered in a variety of forms, thus avoiding monotony in the food.

It is the most nutritious as well as the most economical concentrated food.

Mosquera's Beef Cacao consists of equal parts of beef meal, sugar, and a superior article of Dutch cacao. It does not require cooking, but may be mixed with warm milk, exactly like ordinary chocolate, and so completely is the taste of the beef disguised that it cannot be detected. Requiring, therefore, no previous preparation, it is most conveniently administered.

Antituberculous Vaccination in France.—M. Charles Richet, in the *Revue Scientifique* of November 22, places on record certain experiments in antituberculous vaccination which he carried out in the early part of the present year in conjunction with M. J. Héricourt. He speaks very modestly of his results, and expressly disavows any wish to have it believed that he claims priority over Prof. Koch. As, however, the latter has, up to the present, published no details as to his method of procedure, M. Richet thinks it well to make his own results public simply as a matter of historical fact. The experiments were made exclusively on rabbits, and the following is M. Richet's account of the method which was adopted. Old tubercle cultures were exposed for some time to a temperature of 100° C., so as to kill the living germs, leaving the chemical substances produced by the microbes almost intact. The inoculation of the material thus obtained had, according to M. Richet, never been tried before, or only with negative results. The first experiment was made on April 18, 1890. Of four rabbits vaccinated with this substance, and then inoculated with tubercle, only one died on the forty-second day, not of tuberculosis, but of a tuberculous complication (vertebral abscess), which M. Richet calls an altogether different thing. If this case is eliminated, together with four out of twenty control animals which died of causes independent of tuberculous infection, the results of the experiments were as follows: Of 3 vaccinated rabbits, none died; while of 16 control rabbits, 12 died. In a more recent series of experiments, 5 rabbits were vaccinated, and 3 were used for control. The inoculation was made with very active virus, which was injected into the veins. Under these circumstances inoculated rabbits invariably die within a very short time. On the thirtieth day, of the 3 control rabbits 2 were dead and the third moribund, while the vaccinated animals were alive and perfectly well on November 19, and there was every reason to anticipate that they would continue so.—*Brit. Med. Jour.*

Friedreich's Ataxia.—The patient, a boy aged ten years, was brought to the Barisal Charitable Dispensary on the 7th of August, for a disorder of locomotion. The father stated that the child had enjoyed good health until the age of five or thereabouts, and that his gait then began to alter, becoming awkward and unsteady. It gradually grew worse, and now it is uncertain and tottering, the child walking with his legs placed far apart. Romberg's symptom is not present: there is no nystagmus or double vision, no oscillation of the head or trunk, no rigidities, paralysis or wasting of muscles, no girdle sensation, or anæsthesia anywhere. The knee-jerk is absent on both sides, nor can ankle clonus be produced. The mental faculties are not affected, the boy having a very intelligent face, and replying promptly to any question addressed to him. There is, however, a notable disorder of speech. It is not the "staccato" or "scanning" utterance of insular scelerosis, but consists rather of indistinctness and thickness of speech, so that what the patient says is almost unintelligible. This symptom has developed of late, he being able to talk quite distinctly when younger, and the alteration in his speech was first noticed two or three years after the first sign of disordered locomotion.

Another peculiar symptom is a strange kind of cough, which is evidently neurotic in character. It is frequent, hollow, short—not paroxysmal—and is unattended with expectoration. There is no apparent cause for it, the ears, throat, and thorax having been examined with negative results; while the general symptoms point against its relation with any kind of digestive disorder.

The family history, as far as can be ascertained, is good. The patient's father, who accompanied him, is a healthy man without a neurotic history, nor can insanity or any other neuropathic tendency be traced on the mother's side. The patient has two younger brothers, both of whom are perfectly healthy.

—Brown, *Indian Medical Gazette.*

The Treatment of Sympathetic Ophthalmia.—M. Abadie read a paper on this subject. Sympathetic ophthalmia of the true kind is regarded, since the labors of Leber and Deutschmann, as an affection owning a microbic origin. The microbes coming from the infected focus in the one eye—following a traumatism, for instance—gain little by little the deep parts of the eye, then, penetrating the chiasma, finish by gaining the optic nerve of the side opposite. Now, in order to combat these microbes, the enucleation of the diseased eye was empirically practised. If this be done sufficiently early the propagation of the microbes is probably arrested. But what, he asked, was it best to do when, an eye being wounded, sympathetic ophthalmia declared itself in the opposite eye. In enucleating early the diseased eye, one removed at once, the principal pathogenic focus, the microbes, being as yet but few in number, in the other organ, may not have gained sufficient headway to destroy the healthy structures. Cure is thus quite possible, especially if it be encouraged by mercurial inunctions. Of the microbicidal action of mercury there was no question. If the enucleation, on the other hand, is practised too late without the addition of the mercurial inunctions, it will usually be found that the loss of the second organ of vision results. In conclusion, he said that he would reserve enucleation for those exceptional cases where the destruction of tissue was

so great as to leave little ground to hope for recovery. But before proceeding to enucleation he would first apply the galvano-cautery to the various surfaces of the wound and afterwards inject a drop or two of a sublimated solution of 1 in 100. When in spite of all, either because the case was seen too late or the enucleation was not sufficient, one had to deal with the single eye already profoundly attacked by sympathetic lesions, he advised, before undertaking an operation destined to re-establish vision, waiting until the morbid processes or, in other words, the virulence of the microbes, were got under by repeated injections of a drop or two of sublimated solution.

Peculiar Febrile Affection Prevailing in Nebraska.—I desire to report the general features of a fever that was very prevalent here this fall. The patients would feel indisposed a day or so, then take a light chill, followed by fever of one to three degrees; some cases having the second chill on the next day. Then began a continued fever, ranging from 103° to 105°, usually with little or no pain; no appetite; some having diarrhœa, others constipated; not sleeping for many nights unless having aid.

Of all my remedies, phenacetine gave the best results, given in three-grain doses every three hours. Usually there was no coat on the tongue to speak of, merely a light fur, on a beef-colored tongue, for which I ordered lemonade, ice-cold, or oranges, taken bountifully; which corrected the color of the tongue in all cases. To break the fever I usually gave tincture of gelsemium, ʒj in ʒiv water; of this I ordered one teaspoonful every hour, until the proper time for sleep, then let the patient rest until morning if he could sleep. If not, I gave phenacetine, which not only induced sleep, but in all cases lowered the fever nicely. This course I pursued daily, keeping the patient covered up well until a thorough perspiration occurred, which usually took place in forty-eight hours. I then gave phenacetine every four hours in the morning, and the gelsemium every four hours in the afternoon. Result: not a case lost. Of course, diarrhœa or constipation was looked after. Quinine seemed to exert no good results. There was but little, if any, malaria present in any case, which accounted for the quinine failing to be of any benefit.

This condition of the system was brought about by the continued excessive heat and drougth of the past summer. It could not be malaria, as the air was excessively dry and hot, and there was no decomposition of vegetation going on.

—Humphrey, in *Med. Summary.*

Bromides in the Treatment of Epilepsy.—With the introduction of the bromides came a new era in the treatment of epilepsy. It enabled physicians to obtain a control of the disease hitherto unapproachable. That it has not gained a much greater success than has already been accorded it is owing to lax methods on the part of physicians, and lack of perseverance on the part of patients.

As the bromide treatment must be continued for years, the ill effects of the drug must be carefully studied, that they may be avoided as far as possible. These are: 1. Disturbances of the digestive tract. These can usually be avoided by giving the medicine largely diluted with water, preferably alkaline water, at least one-half gobletful, and if the dose be large, a gobletful. 2. Cutaneous eruptions, especially acne. In some persons the susceptibility to serious cutaneous eruptions is so great as to thwart this method of treatment altogether, but usually it need not interfere with the treatment. To some extent this trouble can be kept under control by arsenic. 3. A blunted condition of the will and intellect is usually more or less marked. If this increases to a great degree, it may be necessary to temporarily diminish the dose, though there often appears to be an adjustment, and the symptoms subside somewhat without reduction of the dose. Often, after the fits have been brought under control, the patient's disposition changes; there is great irritability, etc. But in this case, too, an adjustment seems to take place between the system and the medicine, and the unpleasant manifestations disappear without changing the dose. 4. The bromides sometimes cause impairment of nutrition, so that in badly nourished individuals it must be used cautiously. The use of cod-liver oil, iron, or other tonics, and especially an abundance of nutritious food, may help us over this difficulty. The same tonic course is usually indicated in cases of epilepsy. A weak heart, or valvular disease, also demands caution in the use of the bromides. Digitalis is, in such cases, a valuable adjuvant.

—Zenner, *Journal of Nervous and Mental Disease.*

Hydronaphthol as an Antiseptic. — Hydronaphthol is one of the naphthol series, being a derivative of β-naphthol, and occurs as a whitish powder of fine, flaky crystals. The preparation I used was that of Messrs. Seabury and Johnston, sold by the chemists as hydronaphthol powder. The powder is freely soluble in alcohol, but is, unfortunately, very insoluble in water. It is not wholly soluble in 2,000 parts of cold water. In hot water (above 70° C.) it is much more soluble, but after cooling there is a considerable deposit.

Preliminary experiments conducted in the manner afterwards detailed with a saturated solution, and also with a boiled and subsequently filtered solution (that is, strongest solutions which could be got in water) proved that each, after one hour's exposure, failed to kill staphylococcus pyogenes aureus, though the boiled solution was effective after twenty-four hours. It, therefore, became necessary to obtain a solution stronger than could be obtained in water alone, and to this I attributed the clinical failure of the antiseptic.

I then tried mixing a spirituous solution with water, but the hydronaphtol was at once thrown out when the solution was stronger than 1 to 20 of spirit, while the precipitation occurred more slowly when a solution of 1 to 40 was mixed with water. Glycerine, however, if added to the spirituous solution in excess, prevented this precipitation in water, and I therefore made up a standard solution, thus

Hydronaphthol.....	1 part	1 part,
Rectified spirit.....	10 parts	
Glycerine.....	9 parts,	

making a brown solution of 1 to 100; and with this I was able to get a clear and permanent solution of any strength.

My experiments were designed to test, first, the germicidal, and secondly, the inhibitory power of hydronaphthol. I used a single organism in all the experiments — staphylococcus pyogenes aureus — which I selected both for its ready recognition by its distinctive color and its frequent occurrence. As a preliminary, I demonstrated by plate cultivations that the staphylococcus existed in unimpared vitality in boiled water four days after inoculation.

—Bryce, *British Med. Jour.*

THE *Medical World* contains many suggestions from practitioners, besides useful hints, some old, some original. As a specimen we give the following, taken from the December number:

FINK advocates the carbonate of ammonia highly in pneumonia, especially in bad cases.

OVERLOCK reports a case of threatened abortion in a woman who had already aborted five times. There was some show of blood already She was given drachm doses of viburnum prunifolium (fluid extract?) every hour for four doses; then every three hours, and kept in bed for some days after all symptoms had left her. Three times in the same pregnancy the symptoms reappeared, and were controlled in the same manner. The doctor was rewarded for this plucky fight by delivering the woman at term of a healthy child.

DALIGNY recommends for pruritus hiemalis:

℞.—Acidi salicylici..... ℥j
Pulv. sulphuris..... ℥ij
Vaselinæ..... ℥ij
M.—S. Use night and morning, after ablution.

LUTTERLOH recommends as an escharotic in cancer, lupus, etc.:

℞.—Sanguinariæ..... part. j
Galangal, pulv..... " iij
Zinci chloridi.....q. s.

Mix the powders, and add enough zinc to make a thick paste. Apply ⅛ inch thick to the tumor, and ⅛ inch over healthy skin, and repeat each morning until desired result is obtained.

APPLEWHITE recommends the following posture for epistaxis:

The patient is placed on a table, face upwards, head dropping down to right angle with the body, supported on a stool, and plugging the anterior nares.

FULLER failed to reduce fever in typhoid by the use of antifebrine, until he added quinine.

HORTON reports a primipara at the age of forty-eight years and six months.

LINDSEY reports delivering a woman at the age of fifty-nine years, eleven months and one day; and of triplets at that.

MCKINNON reports a case of strangulated hernia in which he drew off the gas by using a hypodermic syringe; when the bowel returned spontaneously.

THE PREVERTEBRAL HÆMOLYMPH GLANDS.—Dr. W. F. Robertson, of the Royal Infirmary, Edinburgh, in an interesting article in the *Lancet* on this subject, says:

Histology.—It will be most convenient, in describing the microscopic structure of these glands, to take that of the sheep as the type, and afterwards to point out how those of man and the bullock differ from it. A hæmolymph gland may be regarded as consisting of three portions: (1) A capsule immediately within which there lies (2) a large, irregular sinus distended with blood, which extends, as a rule, right around the gland; and (3) a central or lymphoid portion, into which the peripheral blood sinus sends processes. The capsule is thick in relation to the size of the organ. It is formed of dense fibrous tissue, with many non-striped muscular fibers, chiefly in the deeper layers, and a few yellow elastic fibers. The fat in which the organ is imbedded is immediately external to the capsule. The peripheral sinus is in its average width about one-twelfth of the diameter of the gland. It is intersected by trabeculæ of similar structure to the capsule, which freely anastomose and form a sparse network extending from the capsule to the central or lymphoid part. The meshes of this network are filled with red blood-corpuscles, and other cells similar to those found in the central part, and evidently derived from it. The central lymphoid portion is broken up into irregular segments by prolongation of the peripheral blood sinus, which vary greatly in size. The largest of them are crossed by trabeculæ similar to those of the peripheral sinus. They give origin to smaller, finger-like processes, which still further break up the lymphoid part. All these sinuses are lined by a delicate endothelium. The lymphoid part consists of a framework of long, spindle shaped cells, some of which are non-striped muscular fibers. A few elastic fibers are also present. The spaces in the framework are closely packed with cells of various kinds. Many of them appear to be merely lymphoid cells similar to those forming the follicles of a lymphatic gland. They are found everywhere; but aggregations of them, varying in number from three to six in each section, occur, especially near the margin, forming small, rounded masses closely resembling the splenic lymph follicles, but differing from them in having no arterial relations. Another form of cell which is almost equally abundant, is one differing only slightly from the preceding. It is rather larger, its nucleus tends to be oval instead of circular, and the surrounding protoplasm is more abundant. It differs most markedly from a lymphoid cell in its staining reaction, and may thus be readily distinguished from it. In specimens stained with logwood its nucleus, instead of staining very deeply, as occurs in the case of the lymphoid cell, stains very lightly, although darkly stained nucleoli are always present in it. These cells occur throughout the lymphoid portion, but special masses of them are present in the center of the lymph-follicles. A third form of cell is one which occurs in considerable numbers, and is larger than either of the preceding. It exactly resembles an uninucleated white blood-corpuscle, consisting of a large, deeply staining, often reniform nucleus, with well-defined perinuclear protoplasm. The nucleus of this cell undergoes repeated division, so that there is ultimately formed a multinucleated cell. These multinucleated cells are most numerous near the blood sinuses. In some glands they are not very abundant, but in other they are so numerous as to constitute the most conspicuous feature in the field of the microscope. As the nuclei multiply, the cell itself increases in size until those containing several nuclei have nearly three times the diameter of a lymph corpuscle. They evidently enter the blood sinuses, in which they appear as multinucleated white blood-corpuscles. The number of nuclei in them varies within considerable limits. Many have seven or eight, and some have been seen with even more. In specimens stained with logwood and eosine, it may be noticed that the nuclei, as they increase in number, gradually lose their affinity for logwood, and become tinted with eosine, and from their size and contour strongly suggest the possibility that they become red blood corpuscles. A fourth form of cell is one of large size, which is probably developed from the second variety described above, as cells forming an intermediate series may readily be made out. It is from two to three times the size of a multinucleated cell, and is often somewhat triangular in shape. It has a large nucleus, which stains lightly with logwood, and a small, deeply-staining nucleolus. In some, however, no nucleolus can be seen, and in others the nucleus has also disappeared, so that there

is left only a large, usually rounded, protoplasmic mass which stains with eosine. A fifth form of cell is one of considerable interest, but it is not always very numerous. It is about the size of a multinucleated cell, and usually oval in shape. It has a large nucleus, faintly stained with logwood (in specimens stained with logwood and eosine), and a small amount of surrounding protoplasm.

Medical News and Miscellany.

SCARLATINA has appeared at Lumberton, near Mount Holly, N. J.

HEHIR reports a case of rectal ulcer and stricture in a child under two years of age.

A NEW YORK dentist bemoans his hard fate, as he can only get $100 for a day's labor of five hours.

THE yield from the Indian plantations last year amounted to 1,833 lbs. of quinine, and 6,578 lbs. of febrifuge. This is a decrease from the previous year.

HEHIR reports a case of dropsy of the legs, and albuminuria without tube casts, that appeared to be due to tight lacing, and disappeared when the corsets were laid aside.

A COLORED barber is said to have been asked to kiss a baby, the idiot who was the child's mother believing that this would relieve the babe from the pangs of teething.

THE *Bacteriological World* is announced to appear about January 1, as an illustrated monthly, at $3 per annum, edited by Dr. Paul Paquin, of the State University, Columbia, Mo.

DR. WICKERSHAM is having trouble with the postmaster of the town of Almira, in Jefferson. That official has his office in his residence, and, as a member of his family is ill with scarlet fever, people are unable to get their mail.

DRS. E. H. COOVER, H. Hamilton, and T. J. Dunott have been appointed by the Dauphin County Medical Society as a committee to visit the Philadelphia hospitals and inspect the method of employing Koch's remedy for tuberculosis.

THE Homœopathic Hospital, of Camden, has closed its wards. Reasons given: The doctors of that ilk would not attend the patients without pay. The dispensary, which receives $900 a year from the city, is still open. Out of this sum the physicians are paid.

THE Open Court Publishing Co., of Chicago, will publish immediately, in two handsomely-bound and printed volumes, a new, authorized translation of Gustav Freytag's well-known novel, "The Lost Manuscript." This is regarded by critics as the most charming of the famous German writer's works.

SANITAS has made for itself a good record at the great horse show at Madison Square. Notwithstanding the fact that hundreds of horses were stabled there the entire week, everything was pure, pleasant, and odorless.

At the Smithfield and Islington live stock shows, in England, so perfect was the disinfection, even in the piggery, that the Prince of Wales, and other royal visitors, specially remarked upon it. Thus the high success which Sanitas has met in America is but a repetition of its achievements in England.

"AND now, doctor, you will explain to the jury what a compound fracture is," said the lawyer in a suit in Chicago, last week. "It means where an arm and a leg are broken at once," replied the M.D., who is striving to build up a great reputation as a surgeon.

DR. DIXON is reported to have withdrawn all claim to priority in the discovery of Koch's new remedy. Until we know of what this remedy consists, it is not possible to make or deny priority claims. What Dr. Dixon has done, and has published before any one else, is the demonstration of the protective power of sterilized cultures of the tubercle bacillus, in the case of certain animals. The relation of this discovery to Koch's cannot be estimated until the latter has informed us as to the true nature of his remedy.

MASSACHUSETTS MEDICAL SOCIETY (Suffolk District).—The section for clinical medicine, pathology, and hygiene will meet at 19 Boylston place, on Wednesday, December 17, at 7.45 o'clock. Paper: Dr. W. N. Bullard: The Care of Chronic Pauper Epileptics. Dr. L. M. Baker, of Baldwinville; Dr. Edward Cowles, Superintendent McLean Asylum, Somerville; Dr. Walter E. Fernald, Superintendent Massachusetts School for the Feeble-minded; Dr. Everett Flood, Superintendent Hospital Cottages for Children, Baldwinville, Mass.; Dr. Geo. F. Jelly, Boston; Dr. A. R. Moulton, Massachusetts State Board of Health, Lunacy and Charity; Dr. Geo. H. M. Rowe, Superintendent City Hospital, Boston, and others, are expected to take part in the discussion. E. G. Cutler, M.D., Chairman; Albert N. Blodgett, Secretary, 138 Boylston street.

PATENTS, ETC., on medical subjects, issued December 2, 1890:

Dose-measuring bottle	H. S. Herrick	San Francisco, Cal.
Dental-pluggers	J. L. Mewborn	Memphis, Tenn.
Disinfecting apparatus	F. J. Mitchell	New York, N. Y.
Red dye	C. Dreyfus	Clayton, England.
Mixing and tempering linseed meal	O. R. Nelson	Chicago, Ill.
Temperature regulator for liquids	F. V. Bulckens	Oregon, Ill.

TRADE-MARKS.

Liquid remedy for diseases of the eye. (The pictorial representation of an eye, combined with a protractor instrument, having radii converging to, and terminating in the pupil of the eye	E. H. Burnham	Boston, Mass.
Remedies for diseases of the feet. (The word "Creole.")	J. F. Murphy	New Orleans, La.
Remedy for certain named diseases. (The letters "H V.C.")	W. R. Hayden	Bedford Sp'gs, Mass.
Tonic for debility in females. (The words "Balm of Gilead," and the pictorial representation of a resurrection flower, known also as the "resurrection rose of Jericho.")	Balm of Gilead Co.	New York, N. Y.
Stomach bitters. (The pictorial representation of an alchemist seated upon a pile of books, and holding within one hand an herb, and with the other hand holding upon his knee an open book; and having at one side of him a still, and at his feet, in front of him, a pair of scales; the pictorial representation being partially surrounded by a series of medals	J. Thielen	Oshkosh, Wis.

LABELS.

"Lameraux's Antiseptic."	J. Lameraux	Montgomery, Ala.
"Dr. Stephen's Buckeye Cough Cure."	A. F. Stephens	St. Joseph, Mo.
"Curtis' Spruce Balsam." (For Medicine.)	G. S. Curtis	Peabody, Mass.
"Crane's Infallible Rheumatic Remedy."	O. Crane	Brooklyn, N. Y.

—CHARLES J. GOOCH, *Patent Attorney.*
LOCK BOX 76, WASHINGTON, D. C.

Army, Navy and Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from November 25, 1890, to December 8, 1890.

By direction of the Secretary of War, Captain Charles B. Ewing, Assistant-Surgeon, in addition to his present duties, is assigned to duty as examiner of recruits at St. Louis, Missouri. Par. 7, S. O. 275, Headquarters of the Army, A. G. O., November 24, 1890.

By direction of the Secretary of War, First Lieutenant Eugene L. Swift, Assistant-Surgeon, is relieved from further duty and station, at Fort McDowell, Arizona Territory, and assigned to Fort Thomas, Arizona Territory, where he is now on temporary duty. Par. 16, S. O. 282, A. G. O., Washington, December 3, 1890.

By direction of the Secretary of War, Captain James E. Pilches, Assistant-Surgeon, now on leave of absence, will report in person to the commanding general, Division of the Atlantic, for temporary duty at Fort Columbus, New York Harbor, during the absence, on leave, of Captain William E. Hopkins, Assistant-Surgeon. Par. 3, S. O. 278, A. G. O., Washington, D. C., November 28, 1890.

By direction of the Secretary of War, leave of absence for six months is granted Captain William E. Hopkins, Assistant-Surgeon. Par 2, S. O. 278, A. G. O., Washington, D. C., November 28, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending December 6, 1890.

ATLEE, L. W., Assistant-Surgeon. Ordered to examination preliminary to promotion.

MARTIN, H. M., Surgeon. Placed on Retired List, December 4, 1890.

ALFRED, A. R., Assistant-Surgeon. Ordered to the Naval Hospital, Norfolk, Va.

WHITFIELD, J. M., Assistant-Surgeon. From Hospital, Norfolk, and to the U. S. S. "Chicago."

MCCORMICK, A. M. D., Assistant-Surgeon. Detached from U. S. S. "Chicago," and await orders.

KEENEY, J. F., Assistant-Surgeon. Ordered to the U. S. S. "Minnesota."

HARRIS, H. N. T., Assistant-Surgeon. Detached from the U. S. S. "Minnesota," and await orders.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the two weeks ending December 6, 1890.

FESSENDEN, C. S. D., Surgeon. Leave of absence extended seven days. December 4, 1890.

BAITHACHE, P. H., Surgeon. Granted leave of absence for twenty days. November 28, 1890.

HUTTON, W. H. H., Surgeon. To proceed to Solomon's Island, Md., on special duty. November 29, 1890.

SAWTELLE, H. W., Surgeon. Granted leave of absence for ten days. December 2, 1890.

PECKHAM, C. T., Passed Assistant-Surgeon. Granted leave of absence for ten days. December 1, 1890.

HUSSEY, S. H., Assistant-Surgeon. When relieved to proceed to New Orleans, La., for duty. November 24, 1890.

GROENEVELT, J. F., Assistant-Surgeon. When relieved to rejoin station. November 24, 1890.

COFER, L. E., Assistant-Surgeon. Ordered to temporary duty at Boston, Mass. November 24, 1890.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

PHYSICIANS' FAVORITE PHAETON,

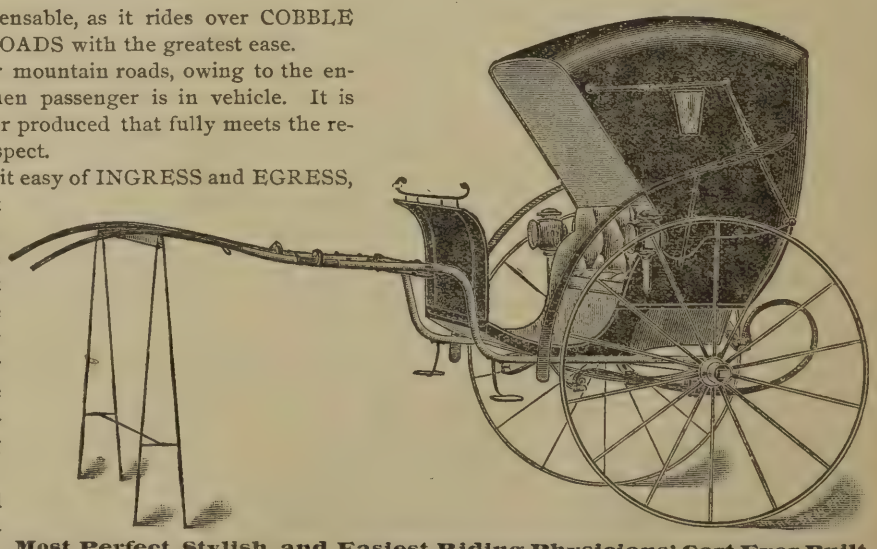
Guaranteed to be Absolutely Free from Horse Motion or Weight on Animal.

THE CHADWICK TWO WHEELER.

For Physicians' use it is indispensable, as it rides over COBBLE PAVEMENTS or FROZEN RUT ROADS with the greatest ease.

It is especially adapted to hilly or mountain roads, owing to the entire absence of weight on animal when passenger is in vehicle. It is entirely new and the only vehicle ever produced that fully meets the requirements of a physician in every respect.

The low hang of the body renders it easy of INGRESS and EGRESS, thus overcoming one of the most monotonous parts of the physicians' practice. In the upholstery of the seat and back, it affords the greatest luxury. Has regular Physician's Close Top, with large side lights, stationary storm apron on dash, large drawer under seat for instruments or medicine case, and is furnished with large serviceable French Cylinder, oil burning reflector lamps when desired.



Most Perfect, Stylish, and Easiest Riding Physicians' Cart Ever Built.

Built with pole for team, instead of shafts when desired, as in the absence of weight on animal, it is the only two wheeler to which a pole can be successfully used. Making it of greater ease and of lighter draught for animal to handle, than any two or four wheeled vehicle ever produced.

Send for Illustrated Catalogue and Price List. Correspondence Solicited.

PYÆMIA AND THROMBOSIS OF INTERNAL JUGULAR VEIN FROM AN OLD OTITIS MEDIA.—LIGATION OF INTERNAL JUGULAR VEIN.—TREPHINING OF MASTOID.—OPENING OF LATERAL SINUS.—DEATH.

BY W. W. KEEN, M.D.,
Professor Principles of Surgery, Jefferson Medical College, Philadelphia.

C. S., aged thirty-one years, letter carrier, married. I first saw him November 16, 1890, at the request of Dr. Jas. F. Berlet.

For the last seven or eight years he has had a slight discharge from the right ear, apparently from cold. Has never had measles or scarlet fever. Has been slightly deaf in right ear.

Annoyed by the discharge, five months ago he consulted an alleged ear specialist, who continued to treat him until four weeks ago, when he made some application to his ears that caused him such pain that in walking to the doctor's office he attracted attention on the street, as he felt and acted as if almost crazy. This was followed by severe headaches, especially occipital. On November 5, 1890, he had a severe chill, followed by fever, and other chills at irregular intervals. Two of them occurred yesterday (November 15) and one this morning, followed by drenching sweats. Two days ago he became slightly jaundiced. Yesterday he had a slight hæmoptysis. Has also great pain in right chest.

Dr. Berlet was called to see him yesterday, and immediately called me in consultation, after making a diagnosis of pyæmia following otitis media. His temperature, taken by Dr. Berlet yesterday morning, was 105.5°, and in the evening, 103°; this morning, 102°, with his pulse pretty steadily at 125. There had also developed a great deal of pain in the right side, from pleurisy, with effusion.

Present Condition: November 16, 1890.—The patient has a very fetid discharge from the right ear, which shows a perforation of the membrane. The mastoid is but slightly swollen or œdematous; is moderately painful upon pressure, with a little pain just above and behind it, but no pain over the course of the lateral sinus between this point and the inion. Over the mastoid process the neck was extremely tender, though but little swollen. The jugular vein could not be felt. He has difficulty in swallowing, and is somewhat hoarse. He is a little jaundiced, and liver rather tender. There is some dullness on the whole of the right side, from slight pleuritic effusion. No headache at present. Beginning choked discs.

Concurring in Dr. Berlet's diagnosis and desperate prognosis, I decided to operate immediately, as it gave him his only, though a very remote, chance for life.

First I trephined the mastoid and evacuated a considerable amount of cheesy pus, which was very fetid. I then chiseled away the bone backward and upward, so as to expose the lateral sinus. Almost immediately on beginning the chiseling I cut the mastoid vein, which bled very freely, but was readily controlled by plugging with iodoform gauze. I exposed, in this way, easily three-fourths of an inch of

the sinus, which looked dirty yellow, with a slight tinge of green and brown at different points. It felt soft to the probe, but was detached from the bone to such an extent that the probe could be passed easily down and forward for over an inch, and evacuated a little offensive pus. I then exposed the jugular vein in the neck. In doing so I found the tissues quite firmly united to each other by inflammatory adhesions, but after some little difficulty exposed the vein, which was thickened, and almost entirely collapsed. A ligature was then thrown around it, an inch and a half above the clavicle—as low as I dared to go. On cutting the vein above the ligature, very little blood oozed out, but fragments of an excessively fetid clot were evacuated from its interior. The odor was so offensive that it was noticed eight or ten feet away. The facial vein, where it entered the jugular, was also thrombosed. The part of the vein from the ligature up the facial was then removed, and the gaping mouth of the vein above sewed to the skin by two stitches.

Next I opened the lateral sinus. The free flow of blood from the mastoid vein had prepared me for abundant hemorrhage, though the discoloration of the wall of the sinus had led me to think that the softened condition might be due to a softened clot. The moment the incision was made, a violent gush of blood showed that there was no thrombus. In an instant I plugged it firmly with iodoform gauze, so that the amount of blood lost was probably not over an ounce and a half.

The wound in the neck was now closed in the ordinary manner, with drainage by horse-hair. The patient was put to bed in a fair condition after so grave a series of operations. His wife had been told, when I saw him, that his chances for life were almost *nil*, and that the only chance lay in operation; and that I was willing to undertake it if she desired it. During the operation his pulse became thready, and $\frac{1}{20}$ of a grain of strychnine was given him hypodermically. This stimulated him, and his pulse, after the operation, was 140, though rather feeble. His color was very good.

He was directed to have two ounces of milk, and one ounce of brandy, every two hours, and as much champagne as he could take.

November 17, 1890. For the first twenty four hours he did very well. His temperature did not rise above 102°, and his general condition was good. He had, however, a second attack of hemoptysis this morning, when he expectorated about an ounce of blood. At 3 P.M., he was suddenly seized with dyspnœa, evidently due to extension of the clot in the jugular into the lungs, or else to the embolus which was detached and passed into the pulmonary vessels. In spite of the most vigorous efforts of the Resident, he died in an hour. No post-mortem could be obtained.

Dr. Barr kindly made a microscopic examination of the vein and clot, and reports as follows:

Jugular vein:—Septic inflammation, infiltration around the cells, much necrotic tissue, micrococci and bacilli present.

Thrombus:—Many pus cells, some red blood cells, many micrococci.

Remarks.—The diagnosis in this case by the doctor who first saw him was: First, chills and fever; and later, when the jaundice set in, disease at the liver.

As soon as Dr. Berlet saw him, it was clear to him, as it ought to have been to any one else, that the case was one of pyæmia. The prior diagnoses are admirable illustrations of the symptoms masking the diagnosis, or, to use a French proverb, the doctor "could not see the forest for the trees." Our prognosis in the case was that of certain death if no operation were performed; and almost certain death even if one were performed. But remembering the cases to be alluded to in a moment, it seemed to us worth while to take the desperate chance.

As to treatment, such cases have, until very recently, gone without any treatment, except the expectant one, which led always to death. Their treatment is of great importance, especially as such cases are not of very infrequent occurrence, as is evident from the fact that Mr. Ballance estimates that, independent of other ear diseases, such pyæmia causes nearly one death a week in London alone.

In 1886, Mr. Horsley (Trans. Clin. Soc. of London, Vol. XIX), I believe, first suggested ligation of the internal jugular in cases of pyæmic thrombosis of the lateral sinus.

In 1889, Mr. Lane (Trans. Clin. Soc. of London, Vol. XXII) reported the first case of purulent thrombosis of the sinus, so operated upon. The patient was a boy of ten years of age, and made a rapid recovery after the ligation of the internal jugular vein.

In the *Lancet* for May 17 and 24, 1890, Mr. Chas. A. Ballance reports four cases, in which operation was followed in two cases by recovery, making three cases of recovery out of five.

The object of the operation is, of course, by ligation of the vein to prevent the extension of the septic clot further toward the heart, or if the clot itself does not extend, to prevent an embolus from it which will do equal damage in the lungs, and, at all events, to prevent further entrance into the circulation of the products of the infective clot. Even in pyæmia without thrombosis of the sinus, if the source of the pyæmic infection is the temporal bone, Mr. Ballance wisely advises ligation of the jugular, and packing of the lateral sinus, for the same reason, namely, to prevent further absorption of the poison.

In the present case the sinus was not trombosed, though to the eye its color indicated such changes as led me to think that it was the seat of septic processes. The treatment, however, was clearly indicated—to prevent the pouring into the circulation of the further septic products of the clot in the jugular vein. Unfortunately, before we had the opportunity to operate, the clot had already extended doubtless to the innominate vein, for I applied the ligature only an inch and a half above the clavicle, and the clot even at that point was so foul that the odor was perceptible eight or ten feet away as soon as the vein was opened. Not being able, therefore, to get between the clot and the heart, the case was regarded by us as hopeless the moment we found such extensive thrombosis. The tissues of the neck were all solidified by the septic inflammation around the vein, so that they had to be dissected apart in searching for the vein, instead of simply loosening them from each other as would be the case in an ordinary neck. This condensation, as well as the partial collapse of the vein, made it impossible to detect the vein itself as a thrombotic cord.

I prefer the method I adopted of first opening the mastoid antrum, and then by gouge and chisel opening the canal for the lateral sinus, rather than trephining.

I think the danger of wounding the sinus is lessened, as the bone is of very unequal thickness at the groove for the sinus, and, besides, it is usually more or less loosened from the bone, as in this case, by a layer of foul pus.

The most important point of all, however, is that

physicians who see such cases early in their history should be impressed with the fact that if a chronic otorrhœa is followed by headache, pain, chills, oscillations of temperature to the extremes, with repeated chills and local œdema, tenderness over the mastoid, over the internal jugular, and over the course of the lateral sinus, and possibly, as in this case, the beginning of optic neuritis, a surgeon should be called as quickly as possible, the mastoid opened, the vein ligated, and the sinus plugged.

As to operative procedure, the plugging of the sinus does not involve any great loss of blood, even if there be no clot. Obstruction of the entire sinus on one side does not involve, it should be remembered, the obstruction of both lateral sinuses, the right being usually continuous with the superior longitudinal sinus, and the left with the sinus rectus (Gray), and with slight communication between them, and sometimes none.

All the papers alluded to are well worth reading by any one who desires to make himself familiar either with the clinical study or the operative procedure.

DOUBLE HARE LIP AND CLEFT PALATE.—PLASTIC OF ALVEOLUS.

By DE FORREST WILLARD, M.D.,
Surgeon Presbyterian Hospital; Clinical Professor Orthopædics, University of Pennsylvania, etc.

C. W., aged ten months. Cleft on the right side entirely through the lip, alveolus, hard and soft palate, extending into and opening the nasal cavity into the mouth. The cleft of the soft palate is half an inch in width. The turbinated bones of the nasal fossa are exposed. The inter-maxillary bones are pushed forward and tilted, so that the extremity of the left alveolar section projects in front of, and overlaps the shorter right alveolus, so that when the jaws are closed the lower maxilla falls fully half an inch behind the upper one, thus preventing any possibility of future mastication. The upper jaw also projects markedly in front of the lower alveolar curve. The skin and soft tissues covering the front of this central inter-maxillary region, are pushed forward, so that they are nearly in a line with the tip of the nose, and there is no nasal projection at that point. The right ala is flat, from its want of bony support. Although the cleft of the lip is double, the alveolus on the left side is not divided. The width of the separation of the alveolar portions on the right side is one-eighth of an inch, and the entire projection, anteriorly, is one-half of an inch.

Operation—As mastication would be impossible in the present condition, the super-maxillary was cut through its alveolar portion by a chisel, opposite and above the first molar teeth on the right side, care being taken to injure the teeth germs as little as possible. The bone was then fractured and pushed back by strong force, applied by the cushion of the hand, until it was brought into line of the other alveolus. As a tendency, however, to return to its former position was still apparent, the fragments were drilled, and wire sutures were carried through each section, and the wires were then shotted, the edges of the alveolus having been freshly pared and freshened before approximation. After the replacement of the soft parts, a long and strong pin was thrust through the lip and through the two fragments, uniting all and holding the jaws firmly in place, while it also acted as a splint for the soft parts. Both the clefts in the lip were then thoroughly pared, commencing at the apex of the triangular spaces, and cutting downward until the red border of the lip was reached, when the partially-severed flesh was permitted to hang with its base still attached to the lip, so as to avoid the loss of any tissue whatever. These four flaps were everted and held out of the clefts, while pins were inserted, so that these projecting flaps might assist in retaining the fullness of the lip, and preventing the deep fissure which so frequently mars the appearance of the border in any operation in which simple paring has been done, and the pared tissue is sacrificed. There will be at first, as is always the case, a redundancy of material; but as cicatrization and contraction occur, shrinkage takes place, and in the course of a year it is not probable that any redundancy will exist. Even should there be any excess, simple snipping with the scissors will suffice to remove it.

The two clefts were united separately with black silk sutures, without the use of small pins. The only pin used was the long one above mentioned. Long strips of adhesive plaster, extending from the neck upon either side diagonally across the lip to the front of the ear on the opposite side, were then applied. The special advantage of these strips being to control muscular action and to keep the parts at rest. When properly applied, these strips are an important part of the dressing, as they splint the whole lower part of the face, and prevent traction by the muscles upon the fresh edges. The long pin, as it had no suture thrown about it, exerted no compression upon the tissue, and it was allowed to remain for five days, to assist in the fixation of the bone fragments. Union of the soft parts was then perfect, and all the stitches were removed, reliance being placed upon the adhesive plaster.

During re-dressing, an assistant's hands should always maintain accurately the position of the flaps, prevent muscular action from the crying of the child, and thus separating the freshly-united tissue.

On the tenth day the small redundant flaps, which had been saved, and which had been stitched with silk, were re-pared at the points where they had failed to unite, after which firm union took place and a small projection marked the line of the cleft instead of a depression, which is usually the case.

The wires were removed on the fourteenth day, and perfect union was found to have been secured between the two portions of the alveolus.

The cleft in the palate, of course, still remains, and will require a subsequent operation, on account of the great width of the opening; or, an obturator may be used.

SOME OBSTETRICAL DON'TS.

By T. RIDGWAY BARKER, M.D.,
Demonstrator of Obstetrics and Chief of the Obstetrical Department in the Medico-Chirurgical College of Philadelphia.

DON'T declare a woman pregnant until you hear the fœtal heart-sounds.

Don't fail to distinguish maternal from fœtal heart-sounds.

Don't forget important additional signs—ballottement, progressive enlargement of uterus and abdomen, etc.

Don't consider a woman necessarily pregnant because there has been cessation of menstruation for several months.

Don't certify that she is not pregnant because she is not married and denies sexual intercourse.

Don't diagnosticate a woman pregnant because enlargement of the mammæ occurs during the first few months following marriage.

Don't accept cessation of menstruation and abdominal enlargement as conclusive signs of conception.

Don't think "morning sickness" and cervical softening pathognomic of pregnancy.

Don't assert that a female is not pregnant because she has a flow of blood from the uterine cavity at her usual menstrual period: decidua vera and reflexa are not in apposition before the third month.

Don't fail to employ the pelvimeter in cases of pregnancy where there are reasons for supposing that there exists an abnormal narrowness of the external pelvic diameters.

Don't consider "morning sickness" uncontrollable and irremediable; look to the diet and forbid all those articles save agents promoting digestion and assimilation.

Don't overlook abdominal distention and increased weight as a possible cause of irritable heart and labored breathing.

Don't allow vesicle irritability and tenesmus to keep your patient awake at night, nor to occasion inflammation and excoriation of the external genitalia.

Don't take for granted that her bowels are regular, but see that your orders in this respect are carried out.

Don't restrict the diet during gestation, it should be of a wholesome and nutritious character—allowances must be made for "cravings."

Don't confine the patient to the house, but encourage the taking of exercise and fresh air.

Don't disregard the state of the nervous system; recollect that it is exalted.

Don't ever consider a case of labor too trivial to require any care and attention.

Don't omit an examination of the mammæ and nipples.

Don't fail to diagnosticate between elevations of the skin about the nipples due to sudden chilling of the areolæ and true tubercles of Montgomery, which are uninfluenced by change of temperature.

Don't delay the employment of remedial agents for the relief of pruritus vulvæ, as it is very distressing.

Don't allow the pregnant female, after the third month, to take any violent exercise, nor to go up and down long flights of stairs.

Don't fail to interdict washing done in cold water, as it is liable to lead to congestion of internal organs of a serious character.

Don't permit her to lift heavy bodies, as such strains endanger the integrity of the membranes and placenta, thus jeopardizing the life of the fœtus.

Don't consent to her taking drives over rough roads, nor in cable cars.

Don't overlook the dangers incident to long railway journeys during the latter months—especially if the railroad has a number of steep grades and sharp curves.

Don't underestimate the importance of ascertaining the source of hemorrhage during gestation; be on the alert for the occurrence of placenta previa.

Don't fail to insist upon rest in the recumbent position for multipara who have previously miscarried during the latter months of gestation.

Don't hesitate to give sedatives freely in cases of threatened abortion or miscarriage to control nervous excitement and allay muscular contraction.

Don't advise her to indulge in social pleasures of an exhaustive nature, nor let her be persecuted by unwelcome visitors.

Don't allow her to be subjected to shocks of electricity, nor loud noises of a terrifying character.

Don't let her witness scenes of an exciting nature, be they extremely tragic or melo-dramatic.

Don't neglect pointing out to her the advantages to be gained by discarding her corsets and other articles of clothing which constrict the movements of the chest and abdomen.

Don't fail to supply the osseous system with abundant material for its nutrition and growth.

Don't forget that the blood during the period of gestation is altered in character, containing a larger amount of water and fibrin, less albumen and red blood globules.

Don't forget mentioning to the primipara that she will most likely "feel life" in the fourth month, and prepare her mind for such an occurrence.

Don't neglect to explain the cause of the purple lines on her abdomen.

Don't omit warning her against wearing tight and insufficient clothing; corsets must be discarded.

Don't recommend very cold nor very hot baths.

Don't sanction the administration of anæsthetics, unless imperatively demanded, lest abortion follow from the violent muscular contractions induced during the stage of excitation.

Don't consent to any operation upon the uterus, vagina, rectum, or bladder which can be postponed until the termination of pregnancy without increasing the risk to the mother.

Don't administer drastic cathartics nor agents likely to unduly excite the muscular walls of the intestinal canal, lest abortion be induced.

Don't insist upon frequent digital vaginal examinations.

Don't disturb mucus in cervical canal.

Don't pass anything, under any pretext, into the cervical canal, in even suspicious cases.

Don't introduce a speculum or tampon unless circumstances demand.

Don't allow sexual intercourse after the third month.

Don't fail to examine urine frequently for albumen and sugar.

Don't think that every woman who is pregnant, and has albuminous urine, must therefore have puerperal aclampsia.

Don't mistake abdominal and uterine intermittent contractions for fœtal movements.

Don't fail to appreciate the significance of "lightening" as indicative of the approach of labor.

Don't mistake the lochia for leucorrhœal discharge.

Don't fail to remove all fœcal accumulations from the rectum before the onset of labor.

Don't disregard the state of the bladder—see that its contents are evacuated.

Don't endeavor, by friction or other means, to hasten delivery in cases pursuing a natural course.

Don't attempt dilatation of the os by mechanical means, unless nature fails or demands assistance.

Don't press upon fundus of uterus during the intervals between pains.

Don't be too anxious to bring about rupture of the membranes.

Don't forget that the worst kind of midwifery is meddlesome midwifery.

Don't fail to follow the uterus as it contracts during the second and third stages, with the hand on the abdomen.

Don't deliver the head too abruptly from under the pubic arch; let the face sweep over the distended perineum.

Don't make traction on the neck, but wait for a pain.

Don't forget the head has to undergo external rotation in order that the shoulders may occupy the antero-posterior diameter of the outlet.

Don't fail to stimulate infantile respiration by friction and change of position.

Don't sever the cord until pulsations cease, except in cases associated with severe hemorrhage.

Don't fail to tie fœtal end before severing.

Don't disturb the placenta for twenty minutes.

Don't allow the uterus to become relaxed.

Don't fail to note the amount of blood lost, and its effect upon the parturient.

Don't omit examining after-birth, to see that every portion of it has been expelled.

Don't introduce the hand or fingers into the uterus unless occasion calls for it.

Don't allow the nurse to touch the person of the patient unless her hands have been rendered as aseptic as your own—a fact of which you are assured.

Don't think that because you order a thing done that therefore it is done, or will be done.

Don't fail to examine, after the third stage of labor, the vagina and perineum for possible lacerations.

Don't put off repairing either, but introduce stitches immediately.

Don't omit warning the nurse about getting soap in the infant's eyes.

Don't permit it to be scrubbed as if it were a kitchen table.

Don't depart without examining the outlets of the infant's excretory apparatus, to see that they are pervious.

Don't have the child removed from the mother's room—change of temperature is likely to occasion pulmonary trouble.

Don't forget the mother while looking after the child.

Don't put the child to the breast for several hours after delivery, that the mother may have some rest.

Don't allow visits from friends for twenty-four hours, or longer, if possible.

Don't take for granted, but see that the nurse does not allow a single soiled or damp article of apparel about the patient.

Don't imagine the risk of a change of clothing is as great as the risk of subsequent infection.

Don't employ ergot in every case after the third stage—wait indications.

Don't fail to order the patient a glass of milk, or other easily-digested fluid, within two hours after her confinement.

Don't permit her to have a drop of alcoholic spirits, unless it is to overcome dangerous symptoms of collapse.

Don't be alarmed by a chill during, or at the close of labor—simply a nervous disturbance.

Don't visit the patient without seeing that the lochia is natural and normal in appearance and amount, and possesses simply its characteristic odor.

Don't allow discharges to accumulate about the external genitalia nor within the vagina, lest they become a source of infection.

Don't postpone the use of intra-vaginal antiseptic injections an hour after the discharge gives forth a fetid odor.

Don't omit taking pulse and temperature; if both do not fall after several hours, explore parturient canal.

Don't overlook condition of bowels and bladder after delivery.

Don't fail to visit patient in from six to eight hours after her confinement.

Don't postpone an examination of the external genitalia of the infant—see that they are properly cleansed daily.

Don't have the child confined in a room flooded with sunlight.

Don't permit the child to be given anything but breast milk and an occasional drink of water.

Don't allow the child to go more than two hours in the daytime without being fed, and three to four hours at night, during the first six months.

Don't let the child fall asleep at the breast with the nipple in its mouth; nor must the breast be given it every time it cries.

Don't neglect to inform the mother that the breast must be bathed with some weak alkaline solution each time after nursing, and then annointed with some simple unguent.

Don't fail to have the meconium expelled at an early date.

Don't take it for granted the child's eyes are all right because you are not informed to the contrary.

Don't declare the mother, after nine days in bed, beyond the dangers of puerperal complications. Involution is a matter of weeks, not days.

Don't administer salines during lactation, unless you desire to diminish the secretion of milk.

Don't allow the breasts to become engorged with milk, lest inflammation and abscess result.

Don't be surprised if breast pumps fail to relieve a hard and tender mammæ; they cannot open up choaked gallactopherous ducts; such a condition requires persistent friction, massage, and hot applications.

Don't presume the infant's tongue is of necessity tied because it cries when it takes hold of the nipple; its gums may be sore, or the milk may be overheated and indigestible.

Don't fail to call attention to the risk the mother incurs in carrying her infant as soon as she is permitted to leave her bed.

Don't keep the child in a "sweat-box," as it were, by bundling it up in blankets.

Don't allow the infant to be tossed about as if it were a foot ball.

Don't grant any one permission to smoke tobacco in the same room with the child, as the fumes are highly irritating to the eyes and respiratory apparatus of the infant.

Don't have the child wrapped up in articles of clothing that have been dyed, lest the poisonous coloring matter comes in contact with the child's person and a high degree of cutaneous inflammation be excited.

Don't expect to succeed in the practice of obstetrics unless you are faithful, attentive, and ever solicitous about the welfare of your patients.

1703 SPRUCE STREET.

THE TREATMENT OF PUERPERAL MASTITIS.

BY CHARLES MEIGS WILSON, M.D.,
Physician in Charge of the Philadelphia Lying-in Charity.

INFLAMMATION of the mammary gland as the result of traumatism is so rarely met with that in this short paper it is unnecessary to consider it. Puerperal mastitis, on the other hand, is a sufficiently common accident; and the consideration of its prophylaxis and management is of very great interest to all engaged in active obstetric practice. The methods

advocated in this short paper are not original, and are not new. Yet they have not been generally accepted; and the mass of the profession still hold to the older and less effectual methods of treating this affection—alike so painful to the patient and so annoying to the practitioner.

The former method of *dry diet*, which lessened the volume of blood and reduced the source of supply from which the mammary secretion was drawn, and the administration of saline laxatives to promote derivative action from the bowels, were excellent in their way. But the old-fashioned topical applications of solutions of camphor, belladonna ointment or plaster, or solutions of atropia, or other agents of a like nature, in the earlier stages of mammary inflammation, as an abortive method of treating mastitis, and the later applications of poultices to hasten suppuration and parsimonious incisions to let out the inflammatory products, have always yielded discouraging results in the experience of the author. On the other hand, the plan of treatment herein advocated has always given happy results.

First, then, let us consider the prophylactic treatment of puerperal mastitis.

In hospital and private practice, the author has latterly adopted the plan detailed below, namely, the patient and nurse are warned against allowing the bowels to become constipated, and, instead of waiting for the customary injection, or dose of oil, on the third or fourth day, gentle action of the bowels is secured upon the second day by the administration of small doses of compound liquorice powder, given in the form of compressed pills—the pleasantest way to administer it—or of the pil. rhei comp., or some gentle laxative of like nature, in small doses, repeated until the desired effect is obtained.

Secondly, the nurse is instructed to wash the nipples with warm water before and after each time that the child takes the breast. After the child is through nursing, and the nipples have been carefully washed and dried, they are smeared with castor oil. This agent was selected because it has what the painters call sticking properties, and because the heat of the patient's body does not cause it to melt and soil the patient's clothing by running over it. For the reasons mentioned it is better than coca butter, or any of the petrolium jellies, for the purpose of anointing the nipples. If the nipple is at all retracted, a Needham nipple-shield is used (with a black-rubber teat substituted for the ordinary white teat furnished with the shield, in order that the child's mouth may not become sore from the lead used in bleaching the rubber). If the nipple becomes chapped or excoriated, the cracks are touched once a day with a 10 per cent. solution of nitrate of silver, applied with a small, camel's-hair pencil. When any overfilling of the mammæ is noticed, as evidenced by turgescence of the subcutaneous veins and the milk ducts, whether the condition of gallactorrhœa be present or not, the patient's consumption of liquid diet is immediately curtailed; gentle saline laxatives, such as drachm doses of the sulphate of magnesia, are given every few hours, until the bowels are freely open. A few circular turns of a four-inch shrunken muslin bandage applied around the patient's chest in such a manner as to make firm compression over the upper and lower third of each breast; and yet in such a manner as not to interfere with the child's ready access to the breast. Or, in place of the circular bandage, the ordinary Richardson bandage may be used.

The simple treatment as outlined above is prophylactic in character, and will generally suffice, unless the inflammation has reached an advanced stage. In those cases where this latter condition has been reached, or where, from the death of the child, it is necessary to suspend lactation entirely, it is the author's practice to cover the breasts with a thick layer of carded wool in order to equalize the pressure and to confine them as closely to the thoracic wall as possible, with double figure of eight thoracic bandage, using always a broad bandage. In doing this, however, care must be taken not to subject the patient to too severe physical pain, or embarrass the respiration by applying the bandage too tightly. No matter how tightly the bandage may be applied, there is no danger of injuring the mammæ if a thick layer of wool be placed over each breast before the application of the bandage. In those cases of more advanced inflammatory action where suppuration is inevitable, early incision of the inflamed area, with efficient drainage under antiseptic precautions, is the best possible means of relief Dry diet, with frequent evacuation of the bowels, obtained by the administration of saline laxatives, to promote derivative action of the intestinal glands, and pressure applied to the mammæ over antiseptic pads, will generally bring about a speedy amelioration of the distressing symptoms that most always attend mastitis.

These hints of treatment for one of the troublesome accidents of the puerperium are offered by the author after a large experience, in which, when they have been adopted, happy results have always attended their use.

DOUBLE PNEUMONIA COMPLICATED WITH ABORTION.

By WILLIAM F. WAUGH, M.D.

DURING the prevalence of influenza last winter, all my cases of pneumonia were treated by the use of hot poultices and the administration of the Febricide pills. These pills contain two grains each of quinine and acetanilide, and ⅙ grain of cocaine. There is nothing secret about them, and the object of this note is not to claim superority for any special maker of pills, but simply to advert to the merits of the formula. While the pills made by the Health Restorative Company were employed for convenience, and proved entirely satisfactory, any reliable retail druggist could prepare them quite as well, except for the coating. But the combination is one of very great value; combining, as it does, an efficient antithermic with a cardiac tonic, and a third drug—quinine—which shares in the action of both the others and has a special effect in combating the tendency to suppuration. Perhaps in no disease do we meet with the indications for this combination so perfectly as in pneumonia. And in the pneumonia prevalent last winter we had an opportunity of putting our methods of treatment to the most severe test offered during the present generation.

My records show that during the grippe period, I attended twenty-three cases of lobar pneumonia; all of which recovered. Ten of these were hospital cases; the remainder occurred in my private practice.

Out of this group I have selected the worst case, as the one which was in the greatest danger of death. She was a stout German woman, illiterate, living in unsanitary quarters, with an inefficient nurse. Everything was against her; yet she recovered. She was about twenty-four years of age, of good constitution and habits, except that she used beer moderately but regularly. I have learned to look upon this as of bad omen in pneumonia. She had been much disturbed

by her baby, about a year old, who had been sick for some time with the influenza. March 1 she was seized with a chill, and presented the characteristic symptoms of pneumonia. The disease rapidly extended to both lungs, until the dyspnœa was extreme. During the first three days my orders were not carried out by the drunken nurse, who was dismissed on March 3. By this time the patient was in a pretty bad state; the respiration being carried on by the upper lobes alone; the lips blue; breathing very rapid; temperature running up to 104.5° and pulse to 136. Vomiting had been troublesome before her illness, as she was about five months pregnant. It was with difficulty we could get any food to remain in her stomach for a few minutes at a time. During the night of March 5 she aborted; losing but little blood, the fœtus coming away easily. By this time the nursing department had been reconstructed, and food, medicine and poultices were attended to very nicely. Crisis occurred March 7, and the case went on to recovery without any untoward incident. The patient was discharged from treatment on March 22; convalescence being somewhat prolonged by the effects of the abortion, and by the bad hygienic surroundings. Alcoholic stimulants were used throughout in the same quantities the patient had been accustomed to before her illness. The above-mentioned pills were the only drugs given, except a few doses of wine of ergot, a teaspoonful each, just after the abortion. The case was watched throughout with the utmost solicitude; and the unexpected recovery was looked upon by all who saw it as a notable instance of the value of the combination employed.

Nor is the treatment of twenty-three cases without a death, during the prevalence of influenza, a record so common as to be undeserving of notice. The great work of Juergensen, in directing attention to the heart as almost the sole source of danger in pneumonia, has never received the general attention it deserves. People recover from pneumonia, in spite of their treatment with antimony, veratrum, aconite, or the depressant antipyretics given alone; and that in sufficient numbers to confirm their medical attendants in the use of these drugs. But the magnificent results of Juergensen, with hundreds of cases, and no deaths except in the aged, have never been paralleled. His methods of cold baths, quinine, red wine and raw beef, seems too peculiar to find general acceptance in this country, where the cold bath has never really extended beyond hospital practice. The object, however, sought in my own method of treatment, is precisely the same as that of Juergensen—to sustain the heart, directly, and by combating the fever that saps the strength of the heart and increases its labor. With him I say: It is the heart, always the heart. Here lies the danger; here must be the remedy. Every means we employ for treatment acts for good only as it strengthens this organ or relieves it of its burdens. Antipyretics accomplish the latter object; it is necessary to see that they do not hurt the patient more by lowering his cardiac power than they do good by lessening the fever.

An Indian story, published last Wednesday in the *Star*, revives the fallacy as to the danger of bringing a frozen person into a warm room. The story tells of an Indian woman who laid out her frozen lord on the ice and thawed him out by dashing buckets of ice-water over him. It has long since been proved that hot applications are most likely to succeed in restoring persons who are frozen.

THE RESORPTION OF IMMATURE CATARACT BY MANIPULATION CONJOINED WITH INSTILLATION.

By L. WEBSTER FOX, M.D.

Some months ago the ophthalmic world was notified by Dr. Kalish, who read a paper before the New York Medical Society, that he had had success in dissipating immature cataracts by massage, boric acid, and glycerine. This new treatment, which promised much, was received by the profession with grave doubts, but by the laity with much hope; especially those who were suffering with immature and mature cataracts. The dread of an operation makes the majority of those afflicted postpone an operation as long as possible. It is only their extreme helplessness which makes them consent at all. A second operation upon a person who has gone through successfully with one eye is never dreaded. Cocaine, aseptic care, a good knife, and a steady hand, usually bring good results. Knowing this, a patient's consent is obtained without much difficulty.

At the last meeting of the same society (November 24, 1890), Dr. Kalish read a second paper, wherein he repeated his assertions and reported continued progress.

Dr. Noyes, in the discussion which followed this paper, regretted that Dr. Kalish had not stated the kind of cataract which he considered suitable, and the kind which were unsuitable for this treatment. As a probable cause for the improvement of vision in certain cases, Dr. Noyes explained as follows: "It meant that the serous fluid which had become effused into the substance of the lens, between the fibres, gradually became spontaneously absorbed, the lens adjusting itself to the new condition, became more homogenous, somewhat more dense, and thereby vision was made better."

There is no doubt that in the earlier stages of cataract, we find an occasional interruption of vision; for some weeks a patient will complain of dimness of his sight, then a clearing up will manifest itself, and so these intermittent stages continue for months. If such a patient were to apply any collyrium at such a period, he would think that he had found a panacea for his cataracts.

Among country people (I speak of the Pennsylvania Germans) there is a popular idea that molasses dropped into the eye afflicted with ulcers of the cornea and cataracts, will cure these diseases. I have just removed a cataract from such a patient; he declared positively that the molasses did clear up his vision when he first applied it, but soon lost its magic power.

A patient has recently been under Dr. Kalish's treatment for two months. The treatment did not benefit this woman at all; although the patient thought that during the first two weeks there was a change for the better, the husband who was in daily attendance upon his wife, could see no improvement. The patient was first examined by myself October 29, 1887. The record at that date shows mature cataract in the right eye; vision of the left $\frac{20}{70}$ sph. + 125 improved to $\frac{20}{40}$, with beginning cataract in this eye. The patient is blind in the left eye to-day. This patient gave the new method a thorough trial, but was not benefited.

If massage will prevent the development of insipient cataract, it is a simple remedy, but we must still have further proof that it will, before it can be put forth as a positive cure.

A CASE OF CHOREA DUE TO THE PRESENCE OF ASCARIS LUMBRICOIDES.

By A. E. ROUSSEL, M.D.,
Demonstrator of Physical Diagnosis Medico-Chirurgical College; Physician to the Southwestern Dispensary, etc.

MAGGIE A., white, aged six years, applied for treatment at the Southwestern Dispensary, November 17, 1890.

The mother states that the child has previously enjoyed good health, as, with the exception of a slight attack of measles when four years of age, she has had none of the other diseases of childhood.

No neurotic family history can be obtained.

About October 1 it is noticed that the child's appetite has become capricious, and that she is now fretful and apt to awaken several times in the course of the night, as if suffering from pain. This continues for a week, when it is remarked that she becomes feverish at night, and a few days later the same symptoms occur irregularly during the day. On the 18th of October, after a more than usually restless night, the mother notices that the muscles of the face have become subject to repeated contractions, and slight irregular movements are also noticed to involve the shoulders, as well as the extremities of the body. These muscular contractions, uniformly distributed on both sides of the body, rapidly increase in intensity, and do not entirely cease during sleep.

Present condition.—Fair physical development, but rather pale and anæmic.

The movements are so violent that the child has some difficulty in maintaining an erect position; the shoulders are violently jerked upward and downward, while the muscles of the extremities are in more or less constant motion. The muscles of the face are equally involved, while the movements of the tongue are so severe as to interfere to a certain extent with articulation.

Sensibility normal; no heart murmur. Bowels are apt to be constipated.

For the last four weeks patient has been treated at another hospital, but symptoms, if anything, have rather increased in severity.

The mother at this time having occasion to administer a dose of oil for the existing constipation notices the presence of a small worm in the stool, and becomes firmly convinced that this is the cause of all the trouble.

Following this indication small doses of calomel and satmin are prescribed, to be taken for three consecutive days.

November 21.—Since last visit six small worms have been passed, and the mother thinks child is considerably better, especially as the movements no longer occur during sleep. In fact there is a noticeable diminution of the choreic movements to be observed throughout the body.

The improvement is so marked that the mother's view is now seriously taken into consideration, and it is determined not to administer the routine treatment, but instead the child is simply given one-half teaspoonful of tinct. cinchona comp. t. i. d.

November 24.—Improvement continues; the muscles of the face are now but rarely contracted, while the movements of the body are much less violent. Articulation but little interfered with; sleeps throughout the entire night.

November 27.—Movements have almost entirely ceased, with exception of slight twitching of the hands.

December 1.—Child apparently well.

December 13.—Discharged cured.

OPERATION ON A GROWTH IN DOUGLAS' CUL DE SAC.

By C. C. MOORE, M.D.

MRS. A., aged fifty-four, married, no children, weight 176 pounds, flabby, but otherwise well-preserved, came under Dr. J. P. Strittmatter's care August 18, 1890, with the following history: About six months ago she began to have pain in the lumbo-sacral region, which pain gradually increased from week to week, and extended down the posterior and anterior parts of the thigh; being most severe on the left side. At intervals, the pain would be felt as a sharp shooting pain over the region of the anterior crural nerve, causing some spasmodic contractions of the muscles supplied by this nerve. Her trouble might easily have been mistaken for neuralgia or rheumatism. The peculiar features of the pain being its sudden accession on certain movements of the body, such as stooping or extreme exertion. The observation of this led to an examination of the pelvic organs, which resulted in finding a very hard round mass, about the size of an orange, with a roughened surface, low down in Douglas' cul de sac, freely movable, not very tender to the touch; but the pain down the thigh and back could be increased by upward and backward pressure of the tumors. Some days later, an anæsthetic was used, and the mass could be outlined with greater precision, and it was concluded that an operation would be the only means of permanent relief.

The tumor was removed by abdominal section September 25, and proved to be the left ovary, which had undergone ossification, and was so solid as to require a saw to make a median section. It was attached to the left horn of the uterus by a pedicle about half an inch long. This short pedicle with two inches or more of adipose tissue of the abdominal walls, made the ligation very difficult.

The patient made an uninterrupted recovery, returning from Dr. Strittmatter's house, where the operation was performed, to her home in twenty-one days. Since then, she has had some numbness and stiffness of the back, no pain on lateral or anterior flexion, but intense pain on posterior flexion.

PHILADELPHIA, 2349 E. Cumberland street,
December 16, 1890.

HIGHER PRELIMINARY MEDICAL EDUCATION. THE INFLUENCE OF THE GERMAN UNIVERSITIES UPON OUR PROFESSION.[1]

By HENRY E. DWIGHT.

FROM the Minutes of the Council, I extract the following authority for the selection of my subject, and its presentation at this meeting of the Academy, by request of the committee.

"In accordance with the leading objects of our organization, the education of the physician both preliminary and technical; the relations of the profession in this country to that of other countries, and the elevation of the literary, scientific and social standing of the profession, are especially appropriate 'subjects.'"

In view of the fact that the constitution was altered at the last annual meeting so as "to admit, in addition to those possessing the degree of A.B. and A.

[1] An address delivered before the American Academy of Medicine, December 4, 1890, at the College of Physicians, Philadelphia.

M., those who can present evidences of preparatory liberal education equivalent to the same"—the subject proposed in the following paper is of *vital importance* at this meeting of the Academy.

SUBJECT.

Influence of German Universities upon the Medical Profession.

I. *What is a University?* It is one thing in America, another in England, and something else in Germany. Hence the importance of a clear definition. The University of London has no teachers, no scholars, no buildings, except a room in the Burlington House, no libraries, no laboratories, and yet it has a brilliant staff of professors in the scientific and medical department. It is simply the Napoleonic University of France, without the principle of teaching. Why not, therefore, have a university without teachers, in this age of printing of many books on every subject? Because, the mind, the voice, the eye of the living instructor is as necessary to-day as in the days of the Athenian Agora, or Academia, with Plato, Aristotle, Socrates, and their pupils. In Germany, by these means, Hegel, in philosophy; Dorner, in theology; Hoffman, in chemistry, and Von Virchow in physiology, have been equally successful.

Hence a university is a body of instructors, teaching the highest knowledge, of the most worth to men, dealing with their dearest interests, appealing to their finest powers and noblest feelings.

To aid them in this blessed work let the university prescribe certain courses, and what rewards shall follow a complete and thorough training; and not for these alone, but let them arrange for those who thirst for knowledge, and earnestly desire the best sources, who should be welcomed to lectures suited to their needs, just as hungry souls pass through church doors always open to satisfy their wants.

Therefore, universities must teach, must vivify knowledge, by appeals to the discoursive reason and the creative imagination. But they must do more—among the services they render when rightly conducted, is the prosecution of scientific research into facts imperfectly examined. True teachers are always progressive, and not content with imparting the conclusions of others. They are investigators for testing the observations of their predecessors, while reaching their own conclusions. In the natural sciences, they will observe phenomena, collect and classify observations, draw inference and force nature to give up her secrets by experiments. Among the greatest teachers in science a large number have been and are now, discoverers.

In such an institution, famed for its teachers, and its original researches, a young student in medicine escapes exclusiveness, because the methods of one science are corrected by those of another. In such an atmosphere, theologians and mathematicians are not intolerant of the votaries of natural science. The student sees a host of men, eminent in genius and industry, who enlarge his horizon by bearing her torch into abstruse paths of knowledge, to masterpieces of thought and feeling which bear fruit in his own mind through life. Hence the catholicity of his views, the elevation of his feelings and the success of his pursuits.

II. *But What Claims Have the German Universities on our Peculiar Attention To-day?* Montesquieu, in his Spirit of the Laws, declared that the English Constitution is found in the forests of Germany, which is abundantly confirmed by Tacitus, and in later days, by Palgrave Kemble and Sir Henry Maine. English customs and laws migrated with the Pilgrims to America. The Germanic system of common fields was reviewed as commons, or town lands, in New England. The Saxon Hege, warden of the hedge, was the pound-keeper of the United States. In the Mayflower's cabin was representative government, and in the Pilgrim's soul there was reverence for law, to be maintained in a legalized organized town, with a church for God's worship and a seminary of learning for man's welfare, on which rested the institutions of a new world. Hence, Harvard and Yale are each the legitimate offspring of Teutonic ideas and German ideals—the "Alma Mater" of a numerous family.

German universities are controlled by the idea that *national unity* depends on *national culture;* that the *powers* that be are ordained of God; and that *rulers are to be obeyed* if they consecrate their *power* to the *welfare of the whole people.* The instruction is by means of lectures and the discussions are conducted by the professors. With the highest instruction in theory, are combined laboratories, clinics and the best apparatus for observation and experiment, to secure practical instruction. Diligence and scholarship are rewarded by degrees which the student must have before he can graduate or enter a profession. *Our colleges* are stepping-stones, like their gymnasia, to a university. We have no institution which the Germans will recognize as a university, and they have none which an intelligent American would recognize as a college. *Their high schools*, with a six years' course, furnish a general education, not a liberal one, and are designed to prepare students for business life. The school for liberal education is the *gymnasium*, with a nine years' course, which pupils begin at nine years of age. Linguistic and historical studies are the peculiar principles of the gymnasium, and as the Minister of Education, Von Gosler, officially declared in 1882, "are designed to prepare for independent study at the University."

The Real Schools, the rivals of the gymnasia, have received their inspiration from the people, and were promoted by progress in natural science, industrial pursuits, and in realism, instead of idealism. They emphasized modern languages, history, mathematics and natural science. The *real* was to be secured by the Real Schools. But German scholars are not prepared to sever scholarship from the ancient classics, to take in their place the modern languages, or translations of the ancients; and the German government prefers the gymnasium, for every position in its gift is accessible to its graduates. German physicians are not ready for such a change, for out of one hundred and sixty-three medical societies only three gave their unqualified consent for the admission of students in the Real School to the university medical department. There are serious complaints by the German government, respecting the efficiency of their medical students, and fear lest the change in the standard of admission to the university medical department might lower the standard of scholarship. They favor an increase of the study of medicine from four to five years to secure better preparation for the faculty.

The testimony of that eminent chemist, Professor A. W. Hoffmann, Rector of the University of Berlin, is very important to all liberally educated physicians. He is certainly one of the ablest instructors in that great university, and means what he says, viz. :—

"That all efforts to find a substitute for the study of the Ancient Classics, whether in the modern languages, mathematics, or natural sciences, have thus

far proved a failure. How often have I heard young men prepared in Real Schools deeply regret that they had not enjoyed the training of a gymnasium. The ideality of academical study, the unselfish devotion to science as science, the free exercise of thought, the condition and result of this devotion, recede in proportion as the classic basis, as training for the university is withdrawn. I have had much occasion to speak of this matter with friends devoted to physics and mathematics, and, with scarcely an exception, I found they had the same conviction."

These are strong words and merit careful consideration. Similar testimony, as to the value of a classical education, has been given by Liebig, the father of agricultural chemistry; Wolff, Hemeberg, Knap, Nobbe, Stohmann, Kühn, and others, all of whom are well-known chemists and discoverers in Germany.

III. *Does the History of Medicine Confirm these Claims?* Are we members of a learned profession? Should we rank with lawyers and theologians on University Catalogues? Have we a scientific profession? These are important questions in America as well as in Germany. Let us see.

Homer mentions two physicians, Machaon and Podalims, skilful in staunching wounds and relieving pain. The story of Æsculapius proves that as far back as legendary history, men made disease and the healing art a special study, and lived by the practice of their craft; but their observations and theories were worth little, because their philosophy was so crude. The labors of Hippocrates are constantly marred by his identification of effect with cause, restrictions placed on the dissections and undeveloped collateral science; still, his work is a monument of unwearied industry and wonderful fidelity to nature. The signs of facts, for the facts themselves, or effects taken for causes, ruined every system of nosology from Hippocrates to Cullen.

There was no sound anatomy or physiology to solve the problems of the diseased system, and not until the *analytical method* of the Alexandrine School pointed to dissection and unlocked the human frame, did true light reveal the phenomena of disease. Herophilus, their most celebrated teacher, made six hundred dissections, and acquired such authority that the proverb remains to this day: "To contradict Herophilus is to contradict the Gospel." But the famous fire at Alexandria destroyed his researches with the library, but not the principles which they discovered, for Philinus, his disciple, left the most important system of early medicine. Philinus urged a return to observation and clinical studies, and was surrounded by a host of observers, among whom was the celebrated Heraclidus of Tarentum, who first introduced opium into practice.

So far scientific medicine is confined to a university—Alexandria, with its literary treasures and learned men. Let us pass from the East to the West, from Egypt to Italy. Pliny assures us that the Roman people had been without a physician for six hundred years. In some things the world is not wiser now than at that period. Then people resorted to certain temples, even in the severest epidemics, as now to the shrine of St. Vitus, where the "faith cure" had its most numerous disciples as well as victims. St. Ossifyga cared for the growth of bones at Rome, just as St. Ursula now cares for them when dead in the Church of the Eleven Thousand Virgins at Cologne.

In Rome, and at this epoch, appeared the Elder Pliny, who collected in his Historia Mundi all the systems from Hippocrates to his own, and has left in his history many original views and reflections, as evidence of the profound mind of a great naturalist.

From Pliny to Galen, the inquiries multiplied exceedingly, because Galen revived the principles of the great physician of Coos, and held undisputed sway in medical matters till the sixteenth century. Devoted to anatomy and physiology, especially the former, his authority became as infallible in medicine as that of Aristotle in philosophy. With Galen, early medicine lost its greatness, and with the downfall of the Roman empire it retrograded likewise, but during the history of that empire, so far as progress was made in the principles and practice of our art, it was on a *scientific* basis. Æsculapius was enthroned "at Rome, and not at Canossa."

The age of Dante was the period of the renaissance, when science was divorced from superstition and charlatanism. The first modern dissection of the human subject was made by Mondini di Luzzi, towards the close of the sixteenth century, when the tone of the European mind influenced art as well as medicine. But the public authorities censured Mondini, and dissection ceased. In the seventeenth century, Vesalius resumed them, and laid the foundation of modern anatomy. The purity of his intentions, and his noble views, removed popular prejudice, which enabled Ambrose Paré first to turn to practical use the labors of his predecessors, and, as surgeon to several European sovereigns, by systematizing the researches of his predecessors, lay the foundations for the structure reared by John Hunter, Dupuytren, Abernethy, and Sir Astley Cooper. During the eighteenth and nineteenth centuries, such stars of the first magnitude as Morgani and Scarpa in Italy; Haller, Börhave, Heister, and Sömmering, in Germany; Dupuytren, and the illustrious Bichat, in France; Cullen, and the Hunters, in England; all eminent physicians and surgeons, continue the work of scientific research in medicine and science, based on facts and not on theoretic principles, in a field of inquiry commensurate with the three physical kingdoms of nature.

Surely, *the Germans have not erred* in their estimate of a classical and scientific training for a physician up to the nineteenth century, if the history of our profession means anything in the development of the race.

What shall I say of *our* century, now drawing to a close? How the labors of our predecessors pale before the wonders of the nineteenth century! Physical examinations, chemical tests, microscopical histology, anæsthetics in surgery, have certainly elevated medicine to a science, and its practitioners to the front rank of her votaries, entitled to the respect and gratitude of all enlightened men. Every tissue of the body is under the microscope, all living organisms are the products of elementary cells, so that every difference of structure implies a difference of function. Thus we mount from the simple cells to the marvelous structure, man, the paragon of animals, the beauty of the world. Under the careful study of the German Kolliker, the liver is revealed as a complex and beautiful structure, symmetrical in design, with an arrangement of lobules, cells, nerves, and blood-vessels, worthy of the warmest admiration, not simply to make bile, but to repair the waste of nerve tissue.

No less, the eye, when under the microscope, bears the happiest results. The discovery of the retinal expansion of the optic nerve, or Jacob's membrane, has wonderfully elucidated the phenomenon of vision. Those nerve fibres are specially fitted to the undulations of light. What a change in our theories of color vision!

Anæsthetics have robbed surgery of all its cruelty and half its danger, extended its sphere of action, increased the proportion of recoveries after severe wounds and mutilation, and insured the safety of obstetrics. Within fifty years the operation of stone will probably become obsolete. Small-pox is no longer a possible danger to life. Typhoid fever is rarely fatal, and typhus is almost unknown, except in the wake of armies or famine. Madness is now a curable disease, and the drugs employed are less loathsome than the disease. Fluid extracts and active principles take the place of nauseating powders and tinctures.

The causes of disease are more thoroughly studied and better understood. From a cold in the head to pulmonary phthisis, from lupus to cancer, bacillus is the password, no matter what may be the "grippe" query. Is the bacillus the cause or a consequence of the disease? Let that star of the first magnitude, now in the zenith of Berlin, so guide our wise men, now about to visit him from the East, that we may all have a quick deliverance from *the scourge* of mankind!

Mr. President, and Fellows of the Academy! I thank you for your patient attention. May I ask for your careful consideration?

THE WEST INDIES AS A SANITARIUM.

By WILLIAM F. HUTCHINSON, M.D.

CHAPTER VII.

PERHAPS the most important of all the West Indian islands as a resort for invalids, is the one we are now about to consider.

All others have some peculiar attractions and characteristic value; this seems to combine most of the former, and to add to the latter some new features that are entirely its own. Situated as it is out of the line of curvature that marks the chains of mountain peaks extending from Northern to Southern Continental America, which we have grown to regard as the only remaining traces of a lost continent, its geological formation differs radically from them all. It is peculiarly and entirely an island that has been built by the unremitting and prolonged labor of coral insects, and as is common with such islands, it possesses a drainage peculiar to them, an almost entire absence of hills and valleys, a slight growth of forest, and a surface almost level and slightly elevated from the sea.

It has, from its discovery, been the only one of the islands that has continuously remained in possession of the mother country.

From its first settlement it has been the home of an educated and civilized body of colonists, who have studied its capability in the light of every modern advantage, and have made it what they claim it is, an epitome of England.

In its teeming population (and there is no spot on earth, not even excepting China, so thickly settled), nothing in the way of schools or means of advance has been forgotten, from its university, which is in close relation with two great English schools, down through its high school and those of lower grade, the utmost possible care has been taken to bring the level of education of its inhabitants to the standard of older lands. People who went there first, carried with them their habits of thrift and comfort, and in the new land where climate was no obstacle to full development, they have succeeded in erecting a class of homes both for themselves and visitors, superior in every way to those of the other islands whose advantages have not been so great.

There is nothing that an Englishman takes greater care of than his personal comfort, and I found in Barbados that this essential item to the traveling invalid had been so thoroughly cared for as to leave little to desire. Even an American hotel is not lacking, kept by an American manager, with meals served upon the American plan; a large, handsome, airy building, capable of accommodating three hundred or more guests, with every comfort that we are accustomed to find in our hotels at home, and not a few of the luxuries. It is true that with the American hotel, American prices have come to the island, and it is

out of the question that one can be housed at the Marine, without paying about as much as he would at a first-class New York or Philadelphia hotel. There are, however, several native institutions of the same kind where the usual island rates prevail, and where one may live as comfortably as possible for the regulation two dollars a day.

Besides the hotels in the city of Bridgetown, there are others on the northern coast; notably the Crane and the one at Bathsheba.

There are no surface streams in Barbados, but beneath, in the white coral that forms the roads and the main part of the island, many feet below the surface, there are rivers that circulate in caves of considerable dimensions, and from one of these pure, fresh water is now supplied in abundance to the city of Bridgetown.

Surface drainage is almost unknown. The porous nature of the land makes any extensive system of sewage quite unnecessary, and in the most crowded sections of the town one may walk about between the thickly built cabins of the blacks, without meeting anything offensive to sight or smell, and this perfection of natural drainage is one of the greatest advantages to invalids that the island possesses. The next is its freedom from mountains and valleys. Unobstructed, the steady trade winds that have come across the sea for thousands of miles sweep from one side of the island to the other, and carry away with them in their kindly arms every atom of miasm and every sign of poisonous vapors. From morning until night, and all the night through, these winds search out through the slightly built and always open houses every corner and cranny, and cleanse it with a besom that knows no stay. The absence of trees to any considerable amount, adds to the general healthfulness of the land by avoiding obstruction to the unremitting play of the beneficent trades.

For this same reason the temperature of Barbados is a particularly steady one. During several weeks of residence upon the island my thermometer marked an average through the day of seventy-eight, with a fall of ten degrees each night. Through the hottest hours, and these were from eleven to four, there would be a rise of ten degrees, and the sun, almost vertical, was reflected back from the white streets and house walls with a force that needed to be protected against; but the winds were so strong, so steady, and carried away from the surface of the body the insensible and sensible perspiration so fast, that the sensation produced was one of comparative mildness, and the danger of sun-stroke to the unaccustomed visitor was greater than it would have been with a higher temperature, without the steady breeze.

One of my party, who was unacquainted with the peculiarity of Barbados in this direction, started for a walk in the middle of one of these bright days, from the Marine hotel to the centre of the town, a distance of about a mile, without the protection of a sun umbrella, which no native would have neglected; he paid for his carelessness by a sharp attack of sun-stroke, and although almost a year has passed, the effects of that blow have not been recovered from. Every one who goes into the street in Barbados at midday, should carry a protection over his head against these powerful, vertical rays. It is better, however, to avoid walking, where cab fare is as cheap as here, and where animals are accustomed to the heat.

The approach to the island is one of extreme beauty. When the traveler has for a week past been studying pictures of scenery of mountain and glen; has been watching in living volcanoes and riven rocks the evidences of terrible forces that have buried a continent, and has been growing accustomed to types of flowers and animals peculiar to volcanic lands, the change is as great as it is pleasant. To the formation of all other islands of the group, to the especial beauties that one has to climb thousands of feet to find, to the deep forests and hill lakes of Dominica, Saint Lucia and Martinique, Barbados is an exception, dressed in light green and white.

Approaching its soft slopes from the westward, one is strongly reminded of carefully cultivated English hills, an illusion which disappears only when the harbor is entered. But while running down the coast from the North, there are few things to mark the difference—at least from twenty miles away.

No mountain ranges accentuate outlines that grow blue as they recede until lost in the bluer sky; no patches of dark color mark where thick forests lie, and no signal gleam from falling water shows where a white cascade catches sun-rays and sends them back to the watcher to tell where it lies hidden in mountain gorge.

Every acre of land is light-green or snow-white at that distance, with dividing lines of color marking fields; and with a strong glass this is resolved into trim farms, with windmills or tall chimneys for steam boilers to give the needed working power. Drawing closer, the land becomes characteristic, and it is plain that a new formation is before us.

There is nothing ancient in these low hills of coral stone, or shelving shores; nothing that appeals to the geologist or naturalist; only a new world for the student of human nature, who finds in this library—whose volumes are mostly bound in black, many a pleasant problem to be worked out beneath a lovely sky and with genial surroundings.

As we sailed into Carlisle bay, the harbor of the island, early in last February, an air of prosperity and business was seen at once. More than a hundred sail, of many flags, were anchored, among them a noble British squadron of nine men-of-war. Boats were pulling about in every direction, and speedily surrounded us to tout for passengers ashore, as we carefully sidled to our position and let go anchor. They carried any and everything, these boats, invariably demanding double fare at first—the custom hereabouts. But we were used to that, and a shilling apiece was all they got. Before us lay the city of Bridgetown, low in buildings, red as to roofs, spread out three miles in length by two inland, dominated by a cathedral tower, and half hidden in greenery. Rounding the breakwater, called the careenage—for they tip vessels half over, here, to scrape them clean—we ran alongside a stone quay and were ashore, to be surrounded by a crowd of darkies intent upon earning a penny from the new-comers. "Here am I, master!" "Your boy John, master!" "I's Uncle Sam boy William, master!" "Dis de way to de ice-house, master!" *Et usque ad nauseam.*

Most travelers who come here report the negroes insolent, devoid of education, and bristling with petty annovance. It is odd, perhaps, but I have never seen all this. They are persistent, it is true; but where human life is crowded as here, and pennies are hard to get, why should they not be? During a stay of weeks in Barbados, I have always found the blacks polite and accommodating, even to each other.

No fault can be found with the food supply in quantity or quality. Besides most of those vegetables which we are familiar with at home, there are one or two others that grow only here, of which the natives are very fond. One is the eddo, which resembles closely our home oyster plant.

I think that the density of population is what impresses a stranger most. It is like living aboard a man-of-war, where men are as thick as bees, and space for another one seems difficult to find. There is absolutely no privacy. Out from the town of Bridgetown, as far as you choose to go, the roads are like streets, with little boxes of houses along the wayside, each holding a numerous family, while troops of negroes stroll along the white way. Sit for a moment beneath a lignum-vitæ or bread-fruit shade, and negroes spring up from the ground to gaze and wonder who you are. This teeming, concentrated human life is the first novelty that a visitor sees.

In an area of one hundred and sixty-six square miles, one hundred and eighty thousand human beings live—and, apparently, live comfortably well. It is, perhaps, the most densely-peopled territory known, and this state of affairs makes itself evident at once in every part of the island.

Streets are crowded from building to building all day long, as a New York pavement is in the forenoon. The people are almost entirely good-humored blacks, clean, and neatly dressed in white. My driver, William, went through this mass at a steady trot, and they got out of the way easily, without a word of such abuse as is common in northern towns, not often needing his warning, "Look out da! Hi!"

My camera was a continual source of wonderment. They know that "De master takes pictures wid dat masheen," but that is all, and its production in the most secluded spot imaginable would bring together within two minutes an audience large, attentive, admiring, but never annoying.

They live very simply, these children of the sun. For food, fruit, flying fish, and yams are nearly enough; are nutritious, and cost but a trifle—say a penny or two a day. For clothes, plain, white material, which covers them completely, except feet, that are always bare, and an aged straw hat, picked up somewhere, is really more than they need in a climate where clothes are a burden, and Edenian attire something to be longed for. Their attire costs little more than fig-leaves.

One of their little houses, in many instances not more ten feet square, can be rented for about $2 a month; and water is free. So they get on very comfortably, and, except from habit, do not often beg. That your dog should come up and ask for food does not seem more natural than that these negroes should hold out their hand for a penny; and the brute animal takes a refusal with much poorer grace than the human. A stranger driving past (and every visitor bears his cachet upon his forehead) represents wealth, intelligence, and undisputed superior authority. Why should he not be asked for a penny? Clearly, there is no reason whatever,

Probably the best way of living, for a family that comes to stay several months, is to rent a house at Hastings or Fontabelle, the two chief suburbs of Bridgetown, and have their own home. A comfortable house for four or five persons can be found for $25 or $30 a month; and servants, better than ours on the average, can be hired at from $1 to $4 a month. There is no difficulty in getting a pleasant place a mile or two from the town, as horse-cars run to all the principal suburbs; and, once at home in the new climate, its highest advantages may be attained.

Artists will find constant amusement and difficult studies in the peculiar color effects that are so hard to catch. Just wherein it lies I cannot tell; but there is something extraordinary in the light of Barbados. My camera, quite trustworthy at home and in the Western Caribbean, played me strange tricks of over and under exposure upon the same plate. No views out of doors can be made instantaneously, and there is no certainty what the developer will reveal.

And the same disturbing element exists with colors. Black and white quite fail to express tropical effects; and so does the brush—at least, as far as I have seen. One may try as hard as possible to catch the green of yonder bread-fruit tree or mass of changing crotons; but before the sketch is done it is usually destroyed—an utter failure. With longer time some one will learn, doubtless; but no one seems to have done it so far.

Driving is a perennial delight. Roads of rare excellence wind in and out of shady groves in town, and extend over the island in every direction. Horses are fair, and can be hired at reasonable prices; so few people walk. A handsome two-horse landau, carrying five beside the driver, can be secured for $8 a day for a journey of twenty miles each way, which will carry one pretty well across the island. Cabs are many, and though wretched in appearance, as a rule, get one about cheaply enough. Twelve cents a mile is certainly a moderate price for two occupants, and that is what the charge is.

One can have a delicious sea-bath every day in the year. A reef of coral sand effectually protects swimmers from the immense sharks that infest all these seas, and the water is of a velvety softness that tempts to long indulgence. Daily baths are a necessity where the skin is so active, and a native would sooner neglect his breakfast than his dip.

The leading industry is sugar, and this year's crop is expected to be a phenomenal one, seventy-five thousand tons being the hoped for yield, which, at three or four cents a pound, will amount to a handsome sum. All the fields of brilliant green are cane, shading up from a delicate pea tint with under color of buff, to a dark grass-green, with whose deep shadows the peculiar light of this island plays strange pranks. Sometimes, watching a field, it is almost black, and then, as sunbeams catch it bending over, it will seem red. Through its tall stalks and hanging leaves the ever-present breeze sings of bountiful harvest and far away seed time, and then speeds on its way. In these fields there is no silence. One may almost see and hear the growth, so plain is the creaking and rustling that is going on around, so rapid the increase in size.

I was writing one morning about six o'clock at Fontabelle, and although the sun was not quite up, the pervading light that is never entirely absent from Barbados was reflected back from the sea to my table through bread-fruit and palm trees, as soft as from a sunset cloud. My thermometer marked seventy, and the nocturnal fragrance was not yet all vanished. Perfumes of roses contended with dying odors of the beauty of the night; and day sounds of birds were taking the place of the night-frog, whose musical double note had scarcely ceased to vibrate. Peace and beauty reigned, and as one deep breath after another of this pure, warm air sent blood to finger tips, life, under almost any pressure, seemed well worth living, and lovely earth very hard to part from. The passionate attachment that these simple blacks feel for their native land is easily explained at charming break of day; and a feeling of contentment pervades every nerve of the visitor who has escaped the chilling frosts and deadly winds of northern lands.

Among the best trips, indeed the very best in Barbados, are those by carriage to St. John's Church and Codrington College, and by train to Bathsheba, which

lies among the wildest scenery of this coast, whose grandest views cannot be very imposing since the land does not reach the altitude of a thousand feet at any point.

In company with Mr. Grundy, the courteous manager of the Barbados Railway, I recently made a visit to the North coast under the most favorable auspices. The little railroad is, itself, a curiosity. Only twenty-one miles long, it has twelve stations that rejoice in most ridiculously inappropriate names; and at every one of them the same amount of form and ceremony was gone through as if a train was leaving Liverpool for London. A black grenadier wore a helmet marked "Railway Police," and scared away small loafing darkeys with majestic wave of hand or suggestive touch of rattan. Porters, with their duty printed in big, red letters on cap-ribbons, rushed about among the six passengers that were going with us, as busily as if a thousand trunks were awaiting demolition; and shouted out, "This train leaves for Rouen, Windsor," etc., etc., with as much pomp as if it were actually starting for those very places in Europe. In a third-class carriage in front, a lot of jolly tars from H. M. S. "Pylades" were off for a day in the country where sugar cane grows and rum is plentiful. One of them had a guitar, and we presently heard a song, whose chorus ended with "From Scilly to Ushant is forty-five leagues."

Barbados is everywhere healthful, but when one feels depressed or exhausted with Bridgetown heat, or needs a little rest from hospitable attention, Bathsheba with its cliffs, its delightfully cool nights and excellent hotel, offers a change that few other West Indian places are able to present.

Among the many insects that fly about evening lamps and in pleasant gardens outside, I noticed a painful lack of brilliant colors. No painted moths nor shining fire-flies are to be seen, and the latter are unknown; so that the island offers none of the attractions to an entomologist that are so rich in Venezuela.

Poisonous reptiles are few and scarce; and St. Patrick must have made a flying trip to Barbados, as far as snakes are concerned. I hear of a few centipedes and scorpions, but they are found only in the neighborhood of sugar estates, scarcely ever being seen in town, so that people who fear inter-tropical lands in general as homes for venemous serpents and insects, may put their apprehensions aside if they conclude to go to this island.

One thing we had come to see was what is called the animal flower cave, a collection of actiniæ in one of the caverns that dashing water has worn in the rock-face, far below surface level, by years of steady toil.

No place, this, for women, so our ladies returned to the carriage and marooned it awhile, which is Barbadian for recuperation physical, while we climbed down a stony sort of chasm, until before us, a little way across, was the cave opening, and leading to it a narrow path along a ridge, steep, wet, and with most hungry looking waves rusing over it at irregular intervals. The guide watched his chance, darted over with a whoop; and watching ours, we followed. The tail end of a ferocious swell caught one fellow and I thought he was gone, but he escaped with a sound wetting, and we called him clumsy.

Inside, the floor was tolerably dry and quite safe, so after a little more abuse for our friend who had scared us so, we went into an inner chamber, and there in a circular basin with a stone floor, reposed a still pool of liquid glass. Now and then its shining surface was gently stirred by trickling streams falling into it, but it was almost incredible that water should be so transparent as this. Where there was no motion, nothing whatever parted eye from crevices in that floor, six feet below.

We gathered around, looking quietly at the water, when what had looked like the dead stem of a water-lily near me began to expand. "Look!" I whispered, in fear of spoiling the show; and in twenty seconds that pool seemed a blazing garden of flowers. With a prevailing color of yellow, of the tint of buttercups, there was enough of red and blue to make purple hues also, which changed as we gazed enchanted, with each slight motion of the plants.

Finally, Jack plunged his hand in after the nearest one, and, presto! the garden was gone, the pool was empty again. Quiet for a moment, and the play began once more, and so we had various acts, all alike. We were in hopes that the colors might change, but they were ever the same.

It is a bad place for rheumatism. Night and day the skin is working to its utmost capacity, and an unnoticed chill stiffens up muscles that refuse with painful persistence to be loosened. Bright's disease and diabetes gain rapidly under the influence of kidney rest, and remain improved, if not transferred too early to northern cold. For those who seek dissipation, who ask "What is there to do down there?" and who demand ceaseless occupation, Barbados is no place.

There is no theatre, no amusement of any kind, and the only departure from such mild fun as driving and sailing furnish, is taken at a social, well-served dinner or a pleasant dance, where each knows all the other guests.

But for quiet, rest and healthfulness, there is but one island of the Atlantic comparable to this, and there Americans find little except climate, and that rated at four dollars a day.

The same suggestions that I have previously made for clothing to be worn on other islands, are equally forcible here, with the exception that one can purchase garments made in excellent style and of the very best English goods, for what seems to be a ridiculously small price. For several years past I have had all my summer suits made there, paying for a first-class article from thirteen to fifteen dollars complete, and for an evening dress suit twenty-five dollars. Lady friends who were with me, fairly revelled in the cheapness of goods. A first-class dressmaker would come and measure her customer at the hotel, bring back the costume complete without ever trying it on, and charge for an ordinary suit, four dollars, for one made of silk, or finer goods with any amount of trimming, six dollars. Of course these prices would not include linings or thread, both of which were purchased by the customer as cheaply as other goods. In these days of increasing prices from tariff vagaries, it is refreshing in the highest degree to be able to purchase a suit of ladies' gear complete for seven or eight dollars, and if upon arriving home changes are necessary to fit them to the reigning fashion, it is more than likely that the least of these will cost more than the original price of the costume.

The only thing that cannot be bought here is shoes, for English feet, both male and female, are larger by several sizes than American, and care must be taken to carry a sufficient supply of foot-gear to last.

There is nothing more beautiful in the world than the play of color over the western sea beneath a setting sun. At Barbados the only difficulty that artists find in interpreting it is to obtain from their color-

boxes tints sufficiently brilliant, and if they do succeed in even a moderate degree in representing the glory of these sunsets, they are sure to be charged with manufacturing in the most absurd manner, combinations that cannot be even dreamed of by those not fortunate enough to have seen them.

This island is a health resort in summer as well as in winter. Invalids from South America and from the neighboring islands, resort here for coolness in July and August, as we of the frozen North for genial warmth in winter months. The result is a constant study on the part of the inhabitants of the wants and needs of travelers, with an effect that is especially comforting to those who go there.

Medical men are thoroughly qualified, competent and courteous gentlemen, and will receive their colleagues from America with a warmth of hospitality that is refreshing to a stranger.

I noticed a few lepers in the streets of Bridgetown, and learned from my friend Dr. Archer, that owing to the careful and stringent sanitary regulations in force, with isolation of these unfortunates, that they have been almost banished from the island and driven from the public streets.

Travelers going to Barbados this winter will fare better than we did last, for extra steamers have been placed upon the lines, with better accommodations and greater comforts. The only warning that I can give to those who think of going there is, that no one of the islands, not even this one, is a fit place for rheumatism in any form, or for advanced lung disease.

FONTABELLE, BARBADOS, MARCH, 1890.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL NOTES.

IN a recent lecture to the class, Prof. Keen gave them the following for preparing chromic acid catgut ligatures:

℞.—Aquæ ..... 2000 parts.
Acid, carbolic ..... 200 "
Acid, chromic ..... 1 "

Then add as much catgut as carbolic acid, viz., 200 grains; soak forty-eight hours, and dry.

Prof. Keen said that ligatures prepared in this way were prevented from being too early absorbed.

In a case of eczema squamosum, treated at the clinic, Dr. Stelwagon recommended tar as a most important remedy, in the following proportion:

℞.—Picis liquidæ ..... f℥j.
Sulphur ..... ℈j.
Ung. simplicis ..... f℥j.
M.—Sig. To be rubbed in morning and evening.

Patient was also advised to keep the hands out of water, as water would tend to irritate the parts, and otherwise increase the trouble.

Dr. J. Solis-Cohen advised the following prescription in a case of irritability of the vocal cords from over-use:

℞.—Tr. benzoini comp.,
Tr. opii camphor. .....āā f℥ss.
Aquæ ferv., q. s.
M.—Sig. Use as a gargle.

And direct the patient to use the vocal cords as little as possible.

Prof. Keen, in his lecture to the class on the antiseptic treatment, said that if instruments were boiled for five minutes in a 1 per cent. solution of sodium carbonate, it would prevent their becoming corroded and rusted, which is likely to follow when boiled in pure water.

FOR WHOOPING-COUGH.

℞.—Antipyrin,
Quininæ sulphat. .....āā ℥ss.
Elix. glycyrrhizæ ..... f℥iv.
M.—S. f℥j every two to four hours.

—*Waugh.*

CASE SIMULATING BRIGHT'S DISEASE.

Waugh presented a case which, from a cursory examination, looked like one of Bright's disease. She complained of lumbar pain, vesical irritability, short breath, and œdema of the ankles—the latter disappearing during the night. But her complexion was ruddy; her vision good; she had no history of headaches, nausea, vertigo, or cardiac disorder. The urine was not albuminous. Inquiry showed that she had had repeated attacks of rheumatism; and the urine was found to be highly charged with uric acid. The œdema of the ankles was accounted for by her weight and her occupation, which kept her standing for most of the time. She was directed to abstain from fluids and from nitrogenous food, and to take alkalies with saline laxatives.

ARISTOL FOR BURNS.

A severe burn occurred from scalding oil. The case was not seen for several hours, when three different applications had already been made to it. These were removed and an ointment applied, consisting of aristol in petrolatum, 20 grains to the ounce. In one week the dressings were removed. The healing had been perfect; not a drop of pus had formed, and the scalded surface was glazed.

—*Waugh.*

ERGOT IN CATARRHAL PNEUMONIA.

In a case of catarrhal pneumonia in an elderly woman, wine of ergot was given in drachm doses every four hours. The threatening symptoms subsided quickly, and recovery ensued.—*Waugh.*

In the Electro-therapeutical Department, conducted by Dr. W. H. Walling, much good work is being done. A few cases only can be cited.

TRANSVERSE MYELITIS.

This patient, referred by Prof. Waugh, was suffering from transverse myelitis, the bladder being paralyzed; the bowels totally inactive; with both limbs involved, the right being anæsthetic and the left partially paralyzed. A short course of galvanic applications restored the patient to comparative health and a restoration of lost functions, he returning to an active occupation.

SUPRA-ORBITAL NEURALGIA.

This patient, an old gentleman, was admitted to the hospital suffering from supra-orbital neuralgia, so intense in character that he could neither eat, talk, or swallow, the least movement of his jaws, or of the supra-orbital muscles giving intense pain. Before resecting the nerve, it was determined to try what electricity would do for him, all medical means having been exhausted in vain. Improvement began with the first application of electricity, and within ten days he was entirely relieved of all pain or discomfort.

POLYCLINIC HOSPITAL.

THE DIARRHŒA OF CONSTIPATION.

IN the course of his remarks on a case that was presented for treatment at the Medical Department of the Polyclinic, Prof. Soloman Solis-Cohen, alluded to the frequency of the condition, which has been called "the diarrhœa of constipation." The patients, as in the case before the class, frequently state that they have had chronic looseness of the bowels for many years. The immediate cause of seeking advice is usually paroxysmal pain, which may stimulate hepatic colic, or as in a case recently seen in private practice, may simulate renal colic. The so-called diarrhœic stools should be carefully examined, and the history carefully inquired into, with the minuteness of a legal cross-examination. The true facts will then be found at variance with the patient's statements. There will be much desire to go to stool rather than frequent passages; and the amount of fæcal matter passed will be found to be very small. The passages are small, thin, serous, foul-smelling, sometimes bloody, usually containing much mucus. Scyballa will occasionally be passed, usually with much pain and difficulty. They are commonly glazed with a glairy mucus, and often faintly blood stained. In other words there is a condition of irritation of the bowel, with insufficient evacuation of the contents. Frequent attempts at defecation, but little result. The paroxysmal pains are due to distension, traction and pressure. When the patient has been in the habit of taking opium mixtures to relieve the supposed diarrhœa, the abdomen may be found greatly distended from paralysis of the intestinal muscular layer. The percussion phenomena will be mingled tympany and dullness, the distribution of the sounds depending on the location of masses of fæces in the bowel. Usually the ascending and transverse colon will be found filled, and the transverse colon may seem to be much dragged down. Pains in the chest may be caused by traction upon the diaphragm. Enlargement of the liver, or ascites, may be mistakenly diagnosticated, unless care is taken to map out the dullness accurately, and not to be misled by the apparent fluctuation of the relaxed intestines. Headache, vertigo, languor, anorexia (sometimes boulimia) nausea, vomiting, are among the chronic or recurring symptoms, other than those already mentioned. The first thing in treatment is to thoroughly wash out the bowel. This may require several irrigations, supplemented by massage of the abdomen. When there is no absolute impaction, calomel may be given in single daily doses of five grains, with soda or aromatic powder, continued for two, three, or four days. Olive oil in large doses and castor oil may also be given by the mouth; or warmed and thrown as high as possible into the bowel an hour or two before the irrigation. After the bowel has been emptied a tonic-laxative pill should be prescribed for continuous use for long periods, with occasional resort to calomel, oil, and salines.

A good formula is as follows:

℞.—Euonymin..... gr. ij.
Ext. ignatiæ..... gr. ss.
Ext. belladonna..... gr. ⅙.
Piperini..... gr. j.
M.—S: One pill three times a day, after meals.

The number of pills daily, or the sizes of the doses, may gradually be reduced as improvement is manifested. Resin of podophyllum, leptaudrin, iridin, and the like may be used with, or instead of, the euonymin. Extract of cascara sagrada is very often useful. The dose is from two to five grains. The ignatia may be replaced by strychnine or nux vomica, the belladonna by hyoscyamus. The commonly used pill containing aloin or aloes is not often useful, and the hemorrhoidal condition present often counterindicates it. Ipecacuanha is often usefully combined with the other agents.

The diet should be carefully regulated. At first it should be restricted to milk (peptonized, or with digestive agents added), beef-tea as a stimulant, thin soups, coffee, and the like. After a little while, when the intestinal irritation and catarrh have subsided, meats and vegetables may be added. Bran bread and other substances intended to assist peristalsis by irritation should not be given. Laxative fruits may be eaten in moderation. Pastry, sweets, and other indigestibles are to be avoided. Plenty of water, preferably hot water, should be drunk. Enemata may be required from time to time, to wash out accumulations, and at first should be given daily, then on alternate days, then weekly, as a routine practice. Abdominal massage, and faradization of the intestines are of great service.

It is quite evident that treatment of the apparent diarrhœa by astringents and opiates is a mistake, and yet this practice is so common as to render it worth while to caution against the error, and to insist on careful examination of the patients. There are other cases of apparent diarrhœa and colic which may turn out to be something quite different on examination. "Walking typhoid fever" is familiar to all; but it is not as generally known as it ought to be, that serious and even fatal results have occurred in cases of perforating appendicitis and other inflammations in the neighborhood of the cœcum, as a consequence of neglect, due to insufficient inquiry into the case. We should never accept a patient's diagnosis, until our own investigations have proved it to be correct.

THE New Jersey Sanitary Association held its Sixteenth Annual Meeting in the Assembly Room of the State House, at Trenton, on Friday and Saturday, December 12 and 13. Papers were read on the following subjects:

The Use of Smoke in Testing House Drains, by Inspector P. L. Lippincott, of Asbury Park.

The Relation of Ground Water to the Health of a Community, by Col. George E. Waring, Jr., C. E., of Newport, R. I.

The Death-rate of Different Localities in New Jersey, by James Owen, C. E., of Montclair.

Annual Address, by the President, George P. Olcott, C. E., of Orange, on Sanitation in House Construction.

What We Do Not Know About the Climate of New Jersey, by Prof. John C. Smock, Ph. D., State Geologist.

Report of Committee on Stream Pollution. C. Phillips Bassett, C. E., of Newark, Chairman.

Deterioration of Water in Reservoirs and Conduits: Its Causes and Modes of Prevention, by Charles B. Brush, C. E., of Hoboken, and Geo. W. Rafter, Civil and Sanitary Engineer, Rochester, N. Y.

Physical Training, by Prof. Chas. H. Raymond, of Lawrenceville.

The Sewers of Trenton, by Prof. Rudolph Hering, C. E., of Philadelphia, Pa.

Discussion on Traps, opened by Ezra M. Hunt, M.D.

CHRISTMAS GREETINGS.

FOR once THE TIMES AND REGISTER has relaxed from the customary sternness of medical journals and has donned Christmas greens and a Christmas spirit. During the past year its success—thanks to you, indulgent reader—has been so marked, and of late tokens of sincere appreciation have poured in upon us from so many sources, that we cannot resist the impulse to celebrate; and feel quite proud of our bright holiday dress.

We take this occasion to thank both our readers and contributors for their warm support, and to assure them of our well wishes for their success, and only wish we could stand without their doors and carol a hearty

> "God rest ye, merrie gentlemen,
> Let nothing you dismay."

With all due modesty, we would also state that if our readers are pleased with THE TIMES AND REGISTER now, they will be more than pleased as time rolls on; for we do not intend to stand still, but will constantly be carrying out plans of improvement and enlargement, so that we hope to be a valuable assistant to the country doctor, a scientific elucidator to the investigator, a reliable help to the city physician, and an upholder of the medical sciences to the entire profession—progressive, fearless, and truthful—we shall also truly be "a thing of beauty and a joy forever."

We trust our pardonable self-praise will be regarded charitably, due allowance being made for the effect of this joyous season upon our editorial staff, and we also trust that our readers will return our wishes for A Merry Christmas and A Happy New Year, and echo with us Tiny Tim's cry of "God bless us, every one."

MAGNETIC HEALING.

THAT inquisitive member of our editorial staff has been on the war path again. This time with the view of ascertaining something about magnetic healing. Dr. Fritz, of Arch street, Philadelphia, was the potent healer from whom the information was obtained. Dr. Fritz is very likely known to many of our readers by the modest advertisements he pleases to insert in Philadelphia's dailies, which frequently contain long lists of cases cured by him.

Our representative found him to be a large, fine-looking man, with a pair of keen eyes, gentlemanly address, of about fifty years of age.

Of course, we had to represent ourselves as a patient, and gave the symptoms of a severe case of "nothing at all," and then sought to draw the "doctor" out, which task was easily accomplished.

Dr. Fritz says he *always* cures, and *never* fails; although he frequently adds medicinal treatment to the magnetic. He confesses that he has no idea what magnetic healing is; "I simply do it, that's all."

Our recent interview with Christian Scientists led us to ask if his method was similar. "Yes," he said, "the results are all obtained in the same way; magnetic healing, hypnotism, Christian science, and electricity are all the same thing."

We know of a certain gynecologist of Philadelphia who would enthusiastically endorse this statement, but won't mention names.

"Do you hypnotise your patients?"

"No; I don't think you could call it hypnotism, although it amounts to the same thing. I don't put them to sleep, but heal them instantly."

"What method do you employ?"

"If the patient has rheumatism, I simply place my hand on the affected limb and ask if he feels pain. 'Yes,' is replied; then I do so—" and here Dr. Fritz frantically waved his hand in front of our representative's face—"and say, 'Throw away your crutches; the pain's gone; you're well.' And, sure enough, he is. Then I tell him to jump about, and stamp his feet, or otherwise use the limb violently, but no pain can be induced."

"To be sure," he added, "this condition may last only a few weeks; but two or three such treatments will produce a permanent cure."

"How do you account for such cures?"

"I don't account for them; I can't explain them; I only know I can do it. But I do not always use it, as few can afford to pay for it; and then it is very weakening, and exhausts me greatly."

"What are your charges?"

"Never less than $10, and up to $100."

"You give stage performances, do you not?"

"Yes; and have greater success in treating people on the stage than in private practice. In such a performance—I had forty-eight last fall—I ask all who wish to be treated to seats on the stage, and go from one to another and heal all. I do not need to ask their symptoms, or what ails them, but simply secure a statement of their troubles for the sake of the audience. I classify patients into *positive* and *negative*. If I go to a negative patient and, when questioning

him, see that he is doubtful or opposing, I will not attempt to heal him, but proceed to a positive or sensitive patient, heal him, and then return to the negative patient, and have no difficulty in healing him."

"Do you use no other treatment?"

"Well, if mechanical trouble exists, I remove the cause. For instance, while I can make the deafest person hear the ticking of a watch inside of five minutes, yet if there is a hard lump of wax in the ear, I will remove this first. Not long ago, at one of my performances, I had a woman brought to me with organic disease of the heart, so bad that she had to be assisted up the platform steps by her husband. I merely layed my hand upon her breast and said: 'You are well, run up and down those stairs!' Her husband was scared to death when he heard me say this, but the woman obeyed and even ran up another flight of stairs, without the least painful results, and is a well woman to-day."

"You say," remarked our representative, "that your method is similar to 'Christian Science,' yet what I know of the latter is that they argue the non-existence of disease or evil."

"That is merely to effect the patient. What doctor does not lie to his patients? Why, d—— it, they all do; so do I. But I have been too open and honest, and were I to begin life over again, I would be dishonest—honest to myself, of course, but dishonest to others."

"This power—is it acquired or a gift?"

"It is a gift. When I first began to heal by laying on of hands, I knew nothing whatever about it, nor do I understand it now. Practice, however, has given me additional skill."

"You say, it is very fatiguing to you?"

"Yes; and in stage performances when I am healing other cases, such a power goes forth that the more sensitive cases can't stand it, even although I am not treating them, and get sick at their stomachs and have to leave the stage."

"Does the act of healing require any mental effort, or any exhibition of will-power on your part?"

"No more will-power or effort, than when I strike this table."

"How do you account for the fatigue?"

"I don't account for it. I don't understand what the power is, anyhow; all I know is that I can do it. I am not an investigator."

"You also say it is similar to hypnotism and electricity. What do you mean?"

"Well, the results are obtained in a similar manner; but in hypnotism only one man out of ten cau be influenced, while magnetic healing is absolulely infallible in every case. Regarding electricity, we know what it does—but who knows what it is? It is a power, that's all we know about it. So it is with magnetic healing, it is a power, but even I who have practiced it for years, don't know what it is."

"Why is it, doctor, that you are looked upon as a quack by the profession?"

"Simply, because I don't conform with their limited ideas. But they are quacks themselves. Look at Dr. ——, down the street, and then Professor ——, and the great Dr. ——, why they are worse quacks than I am by far, and yet they are looked up to by the profession."

Since the gentlemen mentioned are subscribers to this journal, we will mercifully forbear mentioning names.

"Then," Dr. Fritz continued, "look at Brown-Séquard. He was looked upon as a light of the profession until he began to sell a quack-medicine; then he was denounced as a quack. Then, look at Koch! Why d—— it, he'll be called a quack, soon. But then, we are all cranks, all cranks!"

The outlook for the profession had grown so very black that our representative felt inclined to close the interview, feeling that he had obtained as much as the readers of THE TIMES AND REGISTER could bear at one dose; and this inclination became a firm conviction when he read the inscription of a placard over the doctor's desk, which read: "One dollar will be charged for consultations lasting over ten minutes."

Such is magnetic healing; or more correctly speaking, such it is not; and this brings back forcibly the closing lines in The Hunting of the Snark: "For the Snark was a Boojum, you see!" Although the poem sets out to tell what a Snark is, it neglects to inform the reader what a Boojum is, and, therefore, we are left in perplexing doubt as to what either animal actually is.

Annotations.

INFANT MORTALITY.

DR. WILLIAM M. CAPP, of Philadelphia, in a very interesting article on this subject, printed in the San Francisco *Evening Bulletin*, says:

The class of neglected and abandoned infants met with in foundling institutions is peculiarly disqualified for any prolonged struggle, for instance, especially against peculiarly adverse circumstances. They are often the offspring of vicious parents, and with tendencies to disease, and of deficient vitality. To these disadvantages are sometimes added positive neglect and exposure, the ill-effect of which may not be overcome by even the most assiduous subsequent care and attention. Beside, hospital attention to young infants can rarely be equal to the motherly attention of a well-ordered home. It should not, therefore, be surprising that the mortality rate in foundling establishments will be greater than in the general community.

In the official annual statistics of Paris, published in 1880, there were received in hospitals: In 1874, 2,171 foundlings, of whom about 35 per cent., or 758, died within twelve months; 1875, 1,720 foundlings, of whom about 40 per cent., or 694, died within twelve months; 1876, 1,648 foundlings, of whom about 34½ per cent., or 568, died within twelve months; 1877, 1,493 foundlings, of whom about 36 per cent., or 540, died within twelve months; 1878, 1,890 foundlings, of whom about 34 per cent., or 643, died within twelve months; and of those who succumbed during this series of years from 36 per cent. to 48 per cent. in the different years died in the first seven days; from 31 to 43 per cent. died in from eight to fifteen days, and 26 to 38 per cent. died in from fifteen to thirty days.

The "Austrian Statistical Hand-book," published in 1888, gives the following figures, which show such

a low average death rate that one is inclined to think they must be made up upon some plan different from that of the others quoted in this paper. Total number of foundlings in Austria for 1886 reported is 42,877, of whom 5,615 died (13.09 per cent.) Of those retained in hospital 6.71 per cent. died, and of those sent outside to the country 14.97 per cent. died. The averages for the years 1882 to 1885 inclusive are about the same as those given for 1886. It is fair to suppose that many sent from town died, but having been lost sight of, the death did not figure on the records of the institution.

In the Philadelphia Almshouse some years ago, the infant mortality rate was so high that it was mentioned only under the breath, but vigorous measures were instituted to better the conditions, and a decided improvement is manifest. Rigid hygienic rules were enforced, the quality of the food was looked after, and strict antisepsis, chiefly by thorough cleanliness of the feeding bottles and other utensils employed about the children, was insisted upon. Also all the women in the institution who were capable were retained as long as possible to act as wet nurses.

Official statistics upon these subjects are not gathered by the Government in this country.

THE MEDICAL INSTRUCTION OF TO-MORROW.

THE under-graduate colleges of America will, within ten years, abandon all their so-called didatic—or, as Professor Darling used to delight to call them, scholastic—lectures, and give only clinics, demonstrations, and laboratory work. Thus much they will eventually learn from the success of German methods of medical instruction, which are to be found in perfection in the post-graduate schools. Why a man should sit for three or four hours a day, in a badly ventilated room, to hear excellent medical and surgical essays, which he could much better learn from a text-book, or from the grinding of a quiz-master, is beyond enlightened comprehension. It is only the force of custom of a hundred years that continues this. Medicine and surgery can only be taught from the patient, the cadaver, and the laboratory. Long discourses, unillustrated by one of these, are a great waste of time and patience. If the *organization* of under-graduate schools cannot get beyond this, they had better not take up Professor Morrow's idea of seizing the post-graduate schools.

—*The Post-Graduate.*

MASSAGE.

THE tendencies of modern medical practice are toward physiological rather than medicinal treatment. Witness the growing popularity of massage, and of institutions like those of Drs. Ford, Patchen, and Stone, where the gymnastic training of the young is carried out in a scientific manner. How can any parent, who takes pride in the healthy and symmetrical appearance of his children, neglect the opportunities offered by these establishments? When physical development is taken from the rude hands of the illiterate trainer and directed by the skilled physician, there is no longer the danger existing under the old system. In fact, the difference is precisely that between quackery and science; between treatment by persons who are ignorant alike of the nature of the body, of its disease, and of the remedies employed, and intelligent management by the educated physician. As to the art of massage, since it has been developed by men of the great professional skill of Benjamin Lee, its possibilities are becoming recognized. In the treatment of nervous diseases, massage has inaugurated a new era.

THE TIMES AND REGISTER has always taken a deep interest in these matters, and takes pleasure in calling attention editorially to the establishments directed by these gentlemen.

TREATMENT OF TYPHOID FEVER BY HYDROTHERAPY.

DR. E. B. CHASSAGNE, of Kansas City, says: "The author does not exactly follow the directions of Brand, and prefers to use the warm bath gradually cooled down to 60°; it is to be cooled down by cold water poured in, and the water in the bath is kept in constant motion. The duration of the bath should be not under fifteen minutes, nor over thirty; in the majority of cases four baths in the twenty-four hours answer the purpose; in grave cases more baths will be necessary. I give a bath every time the temperature reaches 102°. The patient ought to take his time in leaving the bath, as he cannot take cold; thoracic complications are not produced by chilling, but produced by the fever; and statistics show that they are more frequent under chemical antipyretics than under the cold bath. If, on returning to bed, shivering takes place, the patient ought to be gently rubbed, and a hot bottle placed at his feet. In cases where intestinal hemorrhage appears, ice bags to abdomen instead of baths, and ergotin hypodermically in doses of 2 to 5 grains, according to the case.

Typhoid fever in children is not so fatal as in adults, and, by using hydrotherapic measures, we ought to save most every case.

In conclusion, I will say that chemical antipyretics ought to be left aside, as the only good they accomplish is that patients die with a normal temperature. The statistics show cold facts, and ignorance is the only excuse for not using hydrotherapic means.

—*Kansas City Medical Record.*

PERFECTED OBSTETRICS.

DR. ALFRED L. CARROLL, discussing "the influence of a more perfected obstetric science on the biological and social conditions of the race," has some very pertinent observations on the number of cases of "still-births" and the effect of the present conditions of obstetrical science. For instance, he says:

It is to be regretted that the registration of vital statistics is so imperfect in this country as to preclude any attempt to classify by months the mortality under one year; but the data, such as they are, indicate that, in the United States generally, about 25 per cent. of live-born children die during the first twelve-month.

It would not be unreasonable, perhaps, to assume that at least half of the deaths under one month are attributable to accidents in parturition, and that a large residuum of those occurring in the first year has a similar origin; but the admirable reports of Farr may enable us to go a step farther in the field of inference. The death-rate under one year per 10,000 births in England, for the three years ending with 1875, was 1,527. Of these, 95 were ascribed to the acute zymoses, 29 to "teething," 171 to diarrhœa, 263 to "lung diseases," 98 to tuberculosis, 128 to prematurity, 267 to "atrophy," 14 to "suffocation," and 251 to convulsions, leaving 211 "not stated."

The deaths from prematurity, "atrophy," and convulsions constitute nearly half of the mortality, all of the former and a considerable proportion of the latter two being referable to the time or act of parturition, and some of the pulmonary disorders having their predisposition, if not their origin, in atelectasis at birth. In Farr's March of an English Generation, based on the labor of over thirty years, he computes that the average deaths per million under one year will be 149,493, of which 30,637 will be from diseases of the nervous system, and 21,995 from respiratory maladies. West, taking a wider view of "nervous" disorders, ascribes to these 30.5 per cent. of all the deaths under one year, and to convulsions alone 73.3 per cent. of the "nervous system" mortality—equivalent to 33,421 to the million births. Nor is he any less cogent in his reasoning than in his statistics. The conclusions which he draws respecting the social conditions have the sound of true earnestness which is refreshing. Under this head he says: As regards social conditions, I have little to say beyond expressing the belief that misery rather than midwifery is responsible for most of the degradation which blots our vaunted civilization. It may be that in some cases such misery is the outcome of physical disability dating from birth or parturition, but in more instances it is the result of acquired vicious habits. Social statistics show that the numbers of murders, suicides, and other kinds of crime bear about the same proportion to population every year; but of the ætiology of criminality nothing can be positively affirmed. Even those who dogmatically ascribe all the ill-doings of the world to alcohol have still to find some antecedent factor, and to explain why the vast majority of consumers of alcoholic beverages refrain from crime. Inebriety is often the excitant, but the predisposition must be sought behind it. "*In vino veritas*" has a wider philosophical meaning than they who quote it ordinarily wot of.

The vexed question of heredity (not so much of disease as of proclivity to disease) has little relation to obstetrics, save as it has led some enthusiasts to imagine an impossible prophylaxis by forbidding the marriage of physically, mentally, or morally unhealthy persons, and in this way diminishing obstetric practice, except in illegitimate births; and it is doubtful if anything but a destructively retrogressive midwifery or an increasing prevalence of oophorectomy can materially reduce hereditary morbidity, since delicate, and especially consumptive, women seem to be more apt to conceive and less likely to miscarry than their more robust sisters. As a "glittering generality" it may be asserted that every obstetric advance which saves mothers from invalidism and children from incapacity for future effort must promote the social condition of the race, but politico-economic rules and the inexorable operation of natural laws will probably always overshadow in this respect the influence of medical science, or even of Congressional legislation.

A NUMBER of well-known physicians met last Tuesday evening, at 1403 Locust street, and organized a new club. Dr. O'Hara presided, and P. J. Martin acted as Secretary. The new organization was named the Ambroise Pare Club, after the famous French surgeon of that name. Dr. L. Flick was elected President, and Dr. P. J. Martin, Secretary. Dr. J. Healy, Dr. Prendergast, Dr. C. J. Hoben, Dr. L. F. Flick, Dr. M. O'Hara, Dr. Martin, Dr. T. S. Crowley, Dr. J. H. Wallis, and Dr. Strittmatter were elected as the Board of Directors.

Letters to the Editor.

A CASE OF DIAGNOSIS.

BESSIE H., aged sixteen, American, consulted me about what she supposed was a spinal trouble, as she had treated with one doctor for two years, with only temporary relief, and he sent her to the hospital for treatment, telling her she would most probably have to wear a plaster of Paris jacket, all of which not only worried the girl herself, but also the mother and older sister, who accompanied her on her first visit to the hospital. After questioning her thoroughly, I made an examination, and was much surprised at not being able to find any spinal trouble at all. Instead of there being any curvature I found the spinal column as straight as any. Not considering myself infallible, I called another doctor in to see the case with me, and asked him if he could detect any curvature or other spinal trouble. After thoroughly examining the case, he said he could find no trouble whatever with the spinal column. That being eliminated, I then began searching for the real cause of complaint, and found she was suffering from periostitis of the lower margin and angle of the right scapula, the same existing on the third and fourth ribs, anteriorly; both places were very sensitive to external pressure, and each pressure, unless exceedingly tender, would cause her pain. Upon further inquiry I found that for a year or more it had been her custom to carry to and from school, daily, from twelve to sixteen books, which were placed in a double-ended bag, such as the children now use for that purpose; this was invariably carried on the same shoulder. She also informed me that the teacher forbade their leaving any books at school, even during the noon-hour, and as she went home during that time, it necessitated her taking her books also. She lived ten squares from the school, and thus went over that distance four times daily, which would be equal to her carrying the said books four miles each day, which also caused her right shoulder to be somewhat lower than its companion on the opposite side. The patient's health was fairly good, though there was a bad family history, phthisis being in the family. I began a treatment that day, which was not changed for three months. The result was a complete cure. The last time I saw her, she looked the picture of health, and her sister said she was now gay and cheerful at home, and did not seem like the same girl.

DR. J. R. WALN.

PHILADELPHIA, December 11, 1890.

Book Notices.

THE PHYSICIAN'S VISITING LIST FOR 1891. Fortieth year of publication. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut street.

This list contains all the really useful matter to be found in any of these books, and is still not so large as to bulge out the pockets inconveniently. We do not see how it could be improved.

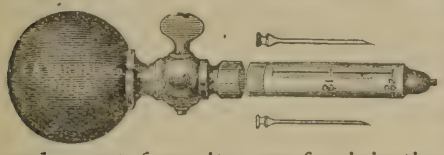
THE MEDICAL BULLETIN VISITING LIST, OR PHYSICIAN'S CALL RECORD. F. A. Davis, Publisher.

This list differs from others chiefly in that the name has to be entered but once a month; short leaves being inserted with the days upon them, one week on each. This is quite a convenience, economizing labor and saving bulk.

New Instruments.

KOCH'S HYPODERMIC SYRINGE.

We are in receipt of a Kock's hypodermic syringe, such as is used by him for his inoculation of the lymph for tuberculosis. The illustration represents the instrument so well as to require little additional description. All the parts are easily detachable, and can easily be kept aseptic. In use, the stop cock is closed, and the glass tube removed and filled; then the needle is attached, the bulb replaced, the stop-cock opened, when, by pressure on the bulb, the fluid may be readily forced out through the needle.



The absence of piston, screws, and packing aid greatly in keeping the instrument clean, and, apart from its use for injecting the lymph, it forms an almost ideal hypodermic syringe.

The instrument is manufactured by Messrs. E. A. Yarnall & Co., of Philadelphia, and we cannot refrain from complimenting them for their enterprise, for they placed the syringe in the hands of the profession simultaneously with the arrival of the lymph in this country. Such zeal deserves recognition and reward from the profession.

The Medical Digest.

FRENCH NOTES.

By A. E. Roussel, M.D.

One of the daily newspapers of Berlin, in speaking of Koch's communication proposes to render the examination of the lungs obligatory, by means of a law analogous to that of vaccination. At certain determined periods each person shall be compelled to be officially ausculted, an examination made of his sputa, and, if there be sufficient cause, to be treated, so that his fellow-citizens shall be protected from any tuberculous contagion on his part.

Latent Cancer of the Stomach.—M. Siredey mentions that an old woman entered the hospital for dyspepsia, with weakness of the legs, but with no signs of cancer, and otherwise in apparently good health. It is true a tumor was noticed in the epigastrium, but that was all, and besides the appetite was good. Death followed after a very short period of vomiting and emaciation. At the autopsy we found a cancer of the pylorus extending over the great curvature; the pylorus would hardly admit of the passage of a small sound.

—*La Médecine Moderne.*

Mortality from Hysterectomy.—M. Terrier reports his results to the *Société de Chirurgie.* By the extra-peritoneal method: In 1883, 2 operations, 2 cures; in 1884, 2 operations, 1 death by peritonitis; in 1885, 5 operations, 1 cure, 4 deaths, of which 3 are from peritonitis and 1 by internal strangulation; in 1886, 6 operations, 3 cures, 3 deaths, 1 from hemorrhage, 1 acute peritonitis, and 1 chronic peritonitis; in 1887, 8 operations, 4 cures, 4 deaths, of which 3 are from peritonitis; in 1888, 5 operations, 5 cures; in 1889, 7 operations, 2 deaths, 1 by hemorrhage, the other by internal strangulation; in 1890, 3 operations, 1 death. Total: 38 operations, 23 cures and 15 deaths. The mortality of hysterectomy by the extra-peritoneal method is 39.47 per 100.

If we divide the 8 years into 2 periods of 4 years, we find that the mortality in the first period is nearly 50 per 100, while in the second period it is reduced 30 per 100.—*La Médicine Moderne.*

Tubercular Peritonitis and its Cure by Laparotomy (König).—Since 1884, when König published his first article on the treatment of tubercular peritonitis by operation, he has collected 131 observations, of which 14 are personal. Of this total, there were 120 women and 11 men, which would seem to prove that numerous operations have been due to errors in diagnosis. Of the 131 cases operated upon, 24 were lost sight of after the operation; 23 were ameliorated, and 84 cured (65 per cent.); some of the cures have been maintained for several years, and he can claim a definite cure for one-fourth of those operated upon; the operative mortality has been 3 per cent.

The mode of intervention has been most variable: simple laparotomy with evacuation of liquid, incision with antiseptic lavage, removal of affected organs, and curetage of tubercular cysts, circumscribed, etc. The employment of antiseptics has had no influence whatever on the result. Cures were obtained in all forms of tubercular peritonitis (serous, suppurating, diffuse, cystic, etc.), and even when the lung and other organs were complicated. According to König, circumscribed intestinal tuberculosis is, in the majority of cases, the cause of tubercular peritonitis. We do not know as yet why, after a simple laparotomy with evacuation of liquid, the intestinal lesion tends to spontaneous recovery; but one fact remains decidedly demonstrated, and that is the frequent and absolute cure of peritonitis by means of operative intervention.

—*Revue de Thérapeutique.*

Treatment of Diphtheria by Iodide of Potassium (S. Zinenko).—The author has obtained very encouraging results by the internal administration of iodide of potassium in diphtheria. It is administered to adults in doses as high as 60 grains a day; children aged from one to fourteen years are given, each day, twice as many grains as they have years. The remedy is continued until the appearance of symptoms of iodism, which is generally noticed from the second to the fourth day of the disease. In case of cardiac weakness, tonic treatment is given at the same time. The author uses neither applications nor cauterization to the throat, as he considers them both irritant and useless. On the other hand he employs the atomizer with a solution of boric or salicylic acid of from two to three per cent. The same is also to be used as a gargle. With children he uses lavage of the pharynx, according to the method of Dr. Stegenski. All the patients receive frictions of mercurial ointment in the region of the sub maxillary glands (22 grains, twice daily). Toward the end of the treatment, hydrochlorate of quinine is given for its tonic effect. This method has been applied in all to 28 persons. Some of the patients died. At the same time, in another service of the hospital, where the patients are treated by other methods, 16 deaths occurred out of 29 cases. In another hospital, where the hygienic surroundings are better than in the service of the author, during the same epidemic, the mortality was 50 per 100.—*Bulletin Général de Thérapeutique.*

The Italian Minister of the Interior has forbidden the use of Koch's lymph, except in the hospital.

Medical News and Miscellany.

TEN THOUSAND DOLLARS' worth of oleomargarine has been seized in Pittsburgh stores, where it was being sold as butter.

FIFTY persons of both sexes in Liverpool have formed a Mahometan congregation. It is thought that this faith may become popular in England.

GAUTEMALA has been invaded by a worse enemy than the Salvadoreans. Small-pox has entered the Central American republic, and has killed 1,200 persons in seven weeks. Physicians are badly needed.

AN alleged analysis of Koch's remedy is cabled to the daily press, stating the components to be: Ptomaines from tubercle cultures, cyanide of gold, and glycerine. As to the cyanide, this is not consistent with Koch's statement, that in three weeks the dose must be increased to five hundred times that first employed. Cyanide of gold is not an agent to be used in any such manner, unless the first dose is infinitesimal.

THE LYMPH AT BALTIMORE.—There are now nine patients at the Johns Hopkins Hospital inoculated with Koch's lymph. Owing to the fact that sufficient time has not yet elapsed, no effect is observed except the usual pain in the back, and desire to cough. The subjects for the experiment were selected with great care, and what are known as free patients. There are many wealthy patients who are waiting to be treated, if the operation proves successful. A new supply of lymph is expected next week.

ALMOST in the exact geographical center of Wyoming is a mountain of solid hematite iron ore, more than a mile wide, and over two miles in length. Besides the iron, the mountain contains lignite coal enough to warm the entire world for a century, a dozen dried up lakes of soda, where the soda is deposited to the depth of over 300 feet, some of the lakes being over 600 acres in extent. In the mountain adjoining there is a petroleum basin larger than those of Pennsylvania and West Virginia combined. Out of some of the springs pure, rectified coal oil is trickling at the rate of twenty or thirty barrels per day.—*Star.*

The lamp-tree probably grows on the mountain slopes; while the Indian residents are a match for anybody.

LADY DOCTORS AT A DISCOUNT.—The native women frequenting the Balrampur Hospital, Lucknow, are so much behind the age that they elect the services of male in preference to female doctors. This is what Dr. Rice, the Inspector General of Civil Hospitals, says on the subject: 'With regard to the 934 major surgical operations done in the female hospitals, it is but right that I should state that the large majority of them have been done by the Civil or Assistant Surgeons, and this is right generally. The greater part of them are of a nature unconnected with the sex of the sufferer. I have, myself, seen women insist that the operations should be done by the male doctor; and not only that, but that they should be done in the male hospital, so as to make sure of his operating. The principle of management is that, as far as this is concerned, every woman shall be left a free agent in the selection of the particular division of the hospital in which she shall be treated."

—*Indian Medical Gazette.*

WITH the object of advancing scientific study and settling a now mooted question, Dr. J. B. Mattison, of Brooklyn, offers a prize of $400 for the best paper on Opium Addiction as Related to Renal Disease, based upon these queries:

Will the habitual use of opium, in any form, produce organic renal disease?

If so, what lesion is most likely?

What is the rationale?

The contest is to be open for two years from December 1, 1890, to either sex, and any school or language.

The prize paper is to belong to the American Association for the Cure of Inebriety, and be published in a New York medical journal, *Brooklyn Medical Journal*, and *Journal of Inebriety.*

Other papers presented are to be published in some leading medical journal, as their authors may select.

All papers are to be in possession of the Chairman of Award Committee on or before January 1, 1893.

The Committee of Award will consist of Dr. Alfred L. Loomis, President New York Academy of Medicine, Chairman; Drs. H. F. Formad, Philadelphia; Ezra H. Wilson, Brooklyn; Geo. F. Shrady, and Jos. H. Raymond, editor *Brooklyn Medical Journal.*

PATENTS, ETC., on medical subjects, issued December 9, 1890:

Nursing-bottle holder	J von Huppmann-Valbella	New York, N. Y.
Forceps for dental wedges	G. J. Davison	Richmond, Va.
Surgical bandage winder	W. Gilfillan	Steinway, N. Y.
Vaginal syringe	J. R Trott	Morrisouville, Ill.
Bleaching hair	F. G. Wiselogel	Indianapolis, Ind.

TRADE-MARKS.

Medicinal cure for gonorrhœa (The words "Stop it sure." with the word "shure" arranged across the face of the words "Stop it")	S. D. Bell	Lexington, Ky.
Cough-syrup. (The words "Persian Cough-Syrup")	Murphy Bros	Jamestown, O.
Topical remed for the cure of corns and other callosities. (The word "Cornease")	The Clark Johnson Medicine Co	New York, N. Y.
Remedy for diseases of the blood, stomach, and kidneys. (The words "Dr. Clark Johnson's Indian Blood Syrup," and the representation of an Indian)	The Clark Johnson Medicine Co	New York, N. Y.
Remedy for bronchial affections. (A monogram of the letters "J. E")	J. Easton	Brockville, Canada.
External application for the cure of headache. (The words "Hedake Kolone")	J. H. Lakin	Boston, Mass.
Condition powders to cure hog-cholera. (The representation of a hog bearing the words "Van Cholera Cure" and the figure of a sickle)	A. J. Van Syckle	St. Mary's, Kan.
Medical preparations for lung diseases. (The pictorial representation of a globe surrounded by a band studded with bottles, in imitation of handles of a steering wheel; two sailor boys above the globe at the wheel; the whole floating within clouds)	F. Leitch	Turtle Point, Pa.

CHARLES J. GOOCH, *Patent Attorney.*

LOCK BOX 76, WASHINGTON, D. C.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

The Times and Register.

Vol. XXI, No. 26. NEW YORK AND PHILADELPHIA, DECEMBER 27, 1890. Whole No. 642.

MEDICAL NEWS AND MISCELLANY, 599

Original Articles.

FATHERS AND SONS.[1]

BY GEO. T. WELCH, M.D.,
PASSAIC, N. J.

WHEN the New Jersey Medical Society was formed in 1766, there was not a hospital in the State; the art of obstetrics was a mysterious and dangerous rite in the hands of midwives; inoculation for the small-pox had but recently come in vogue; yellow fever was creeping up the sounds and rivers, and the children of the horrified colonists were dying like sheep with the "angina suffocativa."

The insane were kennelled at home, and chained when wild and boisterous; their fury was thought to be of Satanic origin, and the evil spirit was whipped over their shoulders with many a rough and biting lash. The clergyman, with reluctance, saw his old legacy of physic diverted from him by aspirants who reverenced only his sacerdotal functions. The conjuror and magician thrived openly. The simpler prowled beneath midnight moons for timely herbs and panaceas. The active principles of drugs were little known; enormous doses of Peruvian or Jesuit's bark were given in fevers, and all other medicines were administered with liberal and heroic hands. Instruments of precision in diagnosis were almost unknown. The opthalmoscope, the spectroscope, the stethoscope, the sphygmograph, the laryngoscope, and the otoscope, the clinical thermometer and the rhinoscope were all inventions of, and came into use in, our century. Specula vaginæ, though known to the ancients, had fallen out of use during the last century, and like the microscope in its wide applicability, are practically new discoveries. Percussion, as a means of eliciting a knowledge of thoracic diseases, though discovered by Auenburger in 1753, and made known in 1761, was neglected, universally, and passed out of memory until 1808. (Snowden.) Auscultation, though known in some obscure way, by Hippocrates, who practised succussion, was discovered (Laennec) in 1816.

Our fathers were like blind men fumbling at the doors of light. They received rays they could not comprehend, and whispers of intuition fretted them with doubts, like unhallowed suggestions from the lips of genii passing in the air.

They were not the practical, reliant men, we have to-day. They were devotees of theory, and tried to coerce nature when in her surly moods she jeopardized health and life. Cullen was the great authority in medical practice, and few dared to go outside of his dictum in these matters, although his pathology and nosology were founded on pure theory. He declared it to be the duty of a physician to control his observations by his theories, and not his theories by his observations. (H. J. Bigelow.) Boerhaave had gone out of fashion; Cullen had come in; Brown was to follow, while the philosophy founded on physiological experiment and clinical observation had scarcely stirred in its germ in a rare mind here and there.

Books were few. From 1775 to 1799, but thirty-nine American medical works were published, and of these but nine ever passed into a subsequent edition, and there was but one medical journal. (Billings.) What a stifling atmosphere were this to the geniuses of to-day, parading each with his fifty cases of malignant disease cured by some new remedy, which, like the New Jersey patent ballot-box, refuses forever thereafter to work at the most critical moment!

Communities are well-nigh frenzied to-day when infectious diseases are rife in their midst, and all that sanitary science can evoke is speedily brought in requisition to check and isolate the plague. But this was not the case during the last century, with the exception of the small-pox, for the houses of the sick were crowded with visitors, and servants and young people waited on the ill by turns. And indeed, it is only within a few years that the practice of congre-

[1] An address made before the New Jersey Medical Society, at its 124th annual meeting, at Schooley's Mountain, June 11, 1890.

gating in great numbers at funerals, and crowding into the room where one lies dead of a fever, has been discontinued. Not but that the writers of that day discountenanced such procedures and advised against them, but the allusions in their works show how prevalent was the custom. I have before me an old work on the Practice of Medicine, printed in 1772, in which the author arguing for fresh air, and against the pernicious habit of shutting up a great number of small-pox patients in one room, he having seen about forty children with the disease, cooped in one apartment, says: "I have seen poor women traveling in the depth of winter, and carrying their children along with them in the small-pox; and have frequently observed others begging by the way-side, with infants in their arms, covered with pustules; yet I could never learn that one of these children died by this sort of treatment." (Buchan.)

How slowly science creeps, before it gathers strength and walks erect, may be instanced in diphtheria; for as late as 1868, I find Condie, in his work on the Diseases of Children, arguing that this desperate malady is not propagated by contagious miasm, but is due entirely to certain endemic or epidemic influences, to which whole localities are exposed, affecting some simultaneously, and others at earlier or later dates. "That it has ever been communicated directly from the sick to the well," says he, "we have not the slightest evidence." It is deplorable that an author can so carry his prejudices into a medical treatise, prejudices which may warp the truth in thousands of minds, but you will all remember the combat Holmes had with Meigs and the elder Hodge, and in which his Damascus blade triumphed, before the world considered it established that, puerperal fever was contagious, and was disseminated by nurses and regardless physicians.

Drugs were used mostly in their crude condition far into this century, and many an atrocious dose passed current in the victim's throat. The millepede, which Cotton Mather apostrophized, and Oliver Wendell Holmes shudders over through all his fibres, was a popular remedy.

One old author of the last century, treating of chincough, (whooping-cough,) says, "The millepedes are greatly recommended for the cure of a chin-cough. Those who choose to make use of these insects, may infuse two ounces of them bruised in an English pint of small white wine, for one night. Afterwards the liquor may be strained through a cloth, and a tablespoonful of it given to the patient three or four times a day." In St. Thomas' Hospital the millepede was used in the preparation of "Balsamic pills," and was said, "to do great service where the lungs were stuffed with viscid or acrimonious juices." But in this same hospital, like a charlatan's prescription, it was found "useful in dropsies, the jaundice, the asthma, and gravel." In St. Bartholomew's the millepede was popular "in all glandular affections."

A wholesome regard for the autonomy of your digestive organs, prevents my more than alluding to a famous broth for invalids which occurs in a book called Practice of Hospitals, now in my possession, but once belonging to a New England physician whose firm hand signed our Magna Charta, the Declaration of Independence. It begins, "Take a viper of middle size, without the head, skin, or entrails; of water, a quart"—I say no more.

But lest the unwary should fall into the error that, the whole art of medicine lagged with the therapeutics of the time, it may not be amiss that I should recall that Boerhaave, Sydenham, and Morgagni strove magnificently to restrain the riot of these crass remedies. Harvey had discovered the circulation of the blood. Haller had demonstrated muscular irritability and its connection with the nerves. John Hunter and Bichat had founded our modern physiology and pathology, and a long line of illustrious names had heaved upward out of the sea of doubts and mysteries to break in tidings at our feet.

But the same conditions have held in the world from the remotest times. When the Cæsars trod in marble palaces, with all the state and retinue of Hyperion of old, there were kings who lived in sheepskin tents and groveled with their minions. When Phidias sculptured Minerva in gold, the lank Lake Dwellers were scrawling their unsightly etchings on the bones of animals. And though from far back in the centuries masters in our art inculcated simplicity in therapeutics, and were the healing spirits of their times, yet the mass of the profession adhered to their confusion of drugs, and do so to this day. As if the art, which is the most progressive in all the world; which peers into the Eleusinian mysteries; which touches the tangible and the intangible chords of life; beneath whose sentient finger flows the hereditary germs that hide in race; which deals with chemistry and spirit, with the individual and the state; whose mercies extend even to the criminal and the insane, the hopelessly maimed in soul and body; as if this art must be tried at last by the druggist's standard, and must rise or fall in the apothecary's diminutive scales!

But the people demanded their *quid pro quo*, and how did they receive it from the fathers?

For the cure of an intermittent it was recommended that, "two ounces of Jesuit's bark, half an ounce of Virginian snake-root, and a quarter of an ounce of ginger, all finely pulverized, be divided into twenty-four parts and made into boluses, of which one shall be taken once in two hours." In a pleurisy the physician was directed to bleed his patient quickly and thoroughly. "Ten or twelve ounces were to be let at once, and if in twelve or eighteen hours the stitch, with the other violent symptoms should continue, eight or nine ounces more were to be taken, and if the symptoms did not abate, a third or even a fourth bleeding was required." A blistering plaster was, also, to be laid on the affected side and suffered to remain for two days. This was said "to actually thin the blood, and by that means to assist in removing the cause." A nurse would have been kept pretty busy with a case of pleurisy on her hands in those days, and it was a common disease, for what with the bleeding and blistering, the regimen, and the multitude of drugs to be given, it was a serious matter for both the living and the dying. The patient was to be continually sipping barley-water, decoctions of figs and raisins, his feet and hands were to be bathed with warm water, fomentations were to be applied to the affected part, strangury from the blisters was to be prevented by drinking a quart daily of the emulsion of almonds, and lest he be costive, he must have clysters of warm water. Expectoration must be promoted by a pectoral decoction containing the vinegar of squills, of which he must take two tablespoonfuls once in two hours, and as this would make him vomit, he must needs take from time to time an electuary of olive oil and syrup of violets, with sugar candy powdered.

To procure perspiration he should have "some small doses of purified nitre and camphor," in his barley-water, four times daily. And to crown all, he must "take of a decoction of seneca rattle-snake

root two, three or four tablespoonfuls three or four times a day, as his stomach will bear it." If he has now had the temerity to survive the crisis, he is gently let down on little shallows of wine whey, until he lies stranded, weak and gasping, this side of the grave, "when, the pain and fever gone, it will be proper to give him some light purges," and other points of etiquette were to be attempted until he had got on his feet and escaped from the house.

So much for a disease self-limited and admitting of cure. But when it came to the confessedly incurable diseases, as phthisis, the physician redoubled his efforts, and multiplied his drugs. His despair of success seemed to embolden him, and it was seldom that he did not declare, as he retired discomfited from the long fight that, had his patient but had the courage to continue the nauseous doses, all would yet have been well.

But surely there is nothing old-fashioned about that. There are few physicians to-day who do not try a shot-gun prescription at an obscure disease—death lurking in ambush might receive a stray pellet and retire. And even in these last ten years, I have known the most maddening variety of drugs administered in pulmonary tuberculosis—digitalis for the swift laboring heart; expectorants for the cough; atropia for the night-sweats; brandy for the weakness; quinine for the fever; ergot for the hæmoptysis; forced feeding and cod-liver oil for the wasting. Then Koch's discovery—the germ—the micro-organism, and the doctors found that they had been dosing the man instead of the disease, and with the utmost *sang froid* they threw away their old weapons, and began with new. Now it is with injections of gases, inhalation of disinfectants, the breathing of baked air, the injection of medicated liquids into the lung cavities. We are after the infinitesimal parasite, and though he holds the man between himself and the faculty it shall be none the better for him, if it should be all the worse for the man.

Whence comes this all pervading worship of drugs! The wierd sisters on the blasted heath, circling before the fatal front of Macbeth, threw into the seething cauldron,

> Scale of dragon, tooth of wolf,
> Witches' mummy; maw and gulf,
> Of the ravin'd salt-sea shark;
> Root of hemlock digg'd 'i the dark,
> Liver of blaspheming Jew,

to work a charm of powerful trouble. And we throw into the vitals of mankind roots, and herbs and seeds; liquors, and gums and oils; sodas, and zincs and leads; poisons and counter poisons, and expect, somehow, to see evolved the charms of perfect cure. Let him who believes that drugs are going out of date, consult the prescription books of the apothecaries.

According to the statistics of "Commerce and Navigation of the United States, 1889," issued by the Secretary of the Treasury, I find that last year there were imported into this country, $13,186,290 worth of drugs. Not all these were to be dispensed to the invalid world, for some were used in dyeing in another way, but the vast majority was for this purpose, and I find, among many familiar items, that there was, of

Cinchona bark...	2,865,968	pounds.	
Opium.....	488,741	"	
Bal. of copaiba....	163,624	"	
Ergot.....	102,275	"	
Asafœdita.....	112,379	"	
Ipecac.....	30,034	"	
Manna.....	25,246	"	
Rhubarb.....	97,820	"	
Carb. ammonia...	656,014	"	
Morphine	20,724	ounces.	
Quinia sulph....	2,893,582	ounces	
Bismuth.....	83,248	pounds.	
Cubebs.....	51,020	"	
Aloes.....	246,270	"	
Iodine.....	186,987	"	
Jalap.....	24,043	"	
Nux vomica.....	426,891	"	
Salicine	8,776	"	
Muriate ammo..	2,381,427	"	
Chlor. potash....	2 525,763	"	

Of the preparations known as alkalies and alkaloids there was importation to the value of $581,693, and of pills, powders, troches, and other proprietary articles customarily prescribed, the value exceeded $418,548. The value of imported opium for the year was assessed at $1,612,942. The cinchona and quinine were valued at $1,326,694.

What feeling of pulses, and sounding of ribs, what thrusting of tongues, and analyzing of fluids, what grouping of symptoms, pausing, weighing and doubting goes with all these vast figures. What despair of patients and complacency of physicians; what rasping of drugs in the apothecaries' pots, rolling of pills, swishing of liquids. The drowsy nurse fumbles at vials, while the clock ticks drearily, and the sick man stares at the yellow ceiling, and groans at the trooping phantasmagoria of his mind. What hard-earned money is swallowed up for his dismal potions, ere he swallows them down. What pinched widows with staring eyes view with dismay the long array of half filled vials, gummed with tinctures and oils, that for all their filthy promises could not keep back life!

But that is the dark side of the picture, for we do save life, and lengthen years, and increase the wisdom of man. Drugs help us to a certain extent, but we have found more powerful magic in mountain air and plunging seas, music, gay converse, riding, driving, wheeling, rowing and travel. The sanitarian saves more to-day than did all the doctors of the last century—Jenner excepted.

It is only when we begin to despair of the virtue of drugs in some thrice mortal complaint that we begin to understand its nature aright, and to treat it upon sound principles. Two centuries ago I find that the practice in London hospitals for the cure of scurvy consisted of ointments, mercurial pills, guiacum, lime-water, antimony, medicated ales, and sea water. We cure it with fruits and vegetables. Small-pox is prevented by vaccination. Phthisis is cured by climate, if it is to be cured at all, and all our curious methods—our oxygen breathing, gas injecting—our inhalations, oils, pneumatic cabinets, cannot avail. Every physician varied his prescription for la grippe, and all got well; every physician varies his prescriptions in acute phthisis, and all the patients die.

Arbuthnot, writing in the middle of the last century, observes that in his time consumptions made up above one-tenth part of the bills of mortality. In ten years in New Jersey, ending with 1889, according to the last report of the Board of Health, out of a total of 230,709 deaths, 31,826 were caused by consumption, or about one-seventh. How we have improved on Arbuthnot with our new methods!

Diphtheria, under a variety of names, but chiefly that of cynanche, created a wholesome dread in the minds of physicians here a century ago. The mortality was very great, frightfully so, in some instances, and a paralyzing dread accompanied it, as a pest in a strange land, but it has now become fixed in its habitat, and is always present, not only in the cities of America, but in all the large cities of the world, and in spite of our modern methods, its slaughter of our innocents is as dreadful as of old. In the epidemic in England from 1854–1859, ninety-five per cent. of all the cases of nasal diphtheria proved fatal. There are epidemics in which the fatality is insignificant, as there are winds which breathe but murmurs of disaster, but anon comes a malignant epidemic which winnows our nurseries with flaming wings, and leaves a trailing pall from home to home, over a wide district, in a day.

In the earliest accounts of the therapeutics of this disease, which I can find, it appears that mercury

had its advocates, as now. That rare letter of Jonathan Dickinson's, written at Elizabethtown, 1738, speaks of the uses of this drug in that connection, and the essay of Dr. James Stratton, read before the New Jersey Medical Society, in 1789, lauds it very highly. He says that calomel affords the most effectual relief in this disease, and adds: "In several cases which have come under my notice, before I became acquainted with the use of calomel, I had the mortification to see bleeding, vomiting, blisters, and every other remedy which the utmost anxiety for the safety of the patient could suggest, prove altogether ineffectual; while on the other hand, in later instances, by the use of calomel only, I have had the satisfaction of seeing the most doubtful cases terminate favorably."

I trust that this was true, but in no other art is there so much danger from self-delusion as in this. Time and again have various authors reported a flattering series of cases, always of the malignant type, which have been cured by the use of mercury, or sulphur, or turpentine, or bromine, permanganate of potassium, chlorate of potassium, the perchloride of iron, and a host of others. The specifics have been numerous, but like the harpies they have devoured each other, while the perchloride of iron stands out pre-eminent as the most reliable of all our specifics here.

In the early days of medical history on this continent, the search for the principles in vegetables and minerals which might be applied to the alleviation and cure of diseases, was very active. Chemistry was pottering for gold, then, and the sunken-eyed alchemist had not found out the art of abstracting it from the pockets of the people, by offering the tempting bait of new and newer drugs. But now it has become an easier way of minting than if a man had the philosopher's stone. The fathers were content with bleeding, blistering, purging, leeching, sweating, vomiting, and applying old wives' remedies. The stout leathern sides of the hardy countrymen were flayed unmercifully, and their stomachs were buffeted about tempestuously with antimony and ipecac, and later with lobelia. The doctors had not then become an exclusive class, a profession limited to a certain work, and denied by the common consent of the public from any participation in the lordlier affairs of life. On the contrary, I find from Wicke's admirable History of Medicine and Medical Men in New Jersey, that, in the last century, out of the very slender ranks of the profession, Beatty, Bloomfield, Burnet, Condict, Dick, Dunham, the two Elmers, Green, Henderson, Pierson, Scott, the two Scudders, and Isaac Smith, were members of the Continental and the United States Congress. Many others were judges, members of assembly, sheriffs, and participants in the local affairs of State.

There have not been many medical Jerseymen during this century, who have lived conspicuously in the political world, and, as things go, so complicated has become the practice of medicine that not even the specialist can rise above the petty details of his profession. Whatever is of the eagle in him is tied down to some organ of our common humanity. By some "devilish cantrip slight," he has got himself into a cell where his horizon is limited to a single object.

The politician does not seek him when he makes up the roll of his candidates; the statesman at his old game of expediency and compromise, does not ask him for a new remedy for society's long ills, and festivals and civic days of pomp find him still plodding his dreary round, into which no trumpet blast comes calling.

Is this as it should be? Is it as it might be? Who is to blame for this isolation of our profession? Foremost it is the doctor himself. The fathers went about among men, interesting themselves in the varied and broad affairs of life, and came to be consulted and approved in other things than medicine. They were none the less successful in their profession, according to their information. The sons, on the other hand, have shunned the opportunities which might have led to a more varied distinction, and, instead of becoming senators, have been content to treat the senator's insomnia, or the lack-lustre of his brain. Human life, after all, is a cheap thing, and all our sacrifices cannot deify it. War makes slaughter of a nation in a day, and our only distress is that such hordes of the enemy escape. Explosions in mines, disasters on railroads, wrecks at sea, and all the minor accidents in town and country, decimate continually the ranks of men. Private feuds, the ignoble labors of the mills, famines—all that might be averted or avoided, claim each their quota of victims. Even when we are at our best, and thwart the desolation of plagues, or remove diseases once thought past all surgery, our sincerest art is expended upon a material elusive and fleeting. Must we then forego all things else to become the ministers of flesh that crumbles before us continually!

If there is honor, glory, pleasure, or distinction to be achieved, compatible with his work, the physician is the man who should have it. Money cannot repay his cheerful subservience in many a loathly disease. He performs duties that were too menial, but for the ray of science that falls athwart and dignifies them. He has learned to distrust praise, and gratitude is a rare virtue, too much like the smile on fortune's face, veneering a frown.

We need the expansive *bonhomme* of the fathers, not their roaring mirth, "with laughter holding both his sides," as evidenced in many a tale told of the provincial and early national days, but we too should taste of the leaven which leaveneth the whole lump of mankind. Nor need we fear to lose caste, or suspect the relaxation which draws the tense mind from its duties, for there were giants in those days as well as now.

But times change, and we change with them. And hereafter, out of the wrecks of the science we laud to-day, will be moulded an art more brilliant and enduring. The tide is setting in a new direction, and preventive medicine will claim the keen attention of the next century. The flood-tide of pharmacy will meet a counter-swell, which will happily overwhelm it, and divers into the sea of our literature will come up aghast at the débris of drugs which cumbered and bore us under.

THE PHYSICIAN AS A WITNESS.[1]

By M. CAVANA, M.D.,
MADISON COUNTY, N. Y.

IT is the aim of the author in this endeavor to place conspicuously before the Fellows of the Association something of his observation and experience, in the attitude of an observer and participant, in the duties of the physician as an expert witness; trusting that the attempt may result in benefit to those of our number, if any there be, who have yet to experience the ordeals of a professional expert in our higher courts of justice.

Being a firm believer in the demonstrative methods of teaching, the author has attempted in this article

[1] Read before the N. Y. State Medical Association.

to reproduce such actual examples in language, and other minute detail, as, in his judgment, best illustrate the subject in question.

The yielding of testimony upon questions of fact, and opinions deduced from a scientific consideration of matters of theory and hypothesis, before a crowded assemblage in a court of justice, constitutes at the present educated age, a function of the physician and surgeon of an importance that demands far greater care and attention on the part of our profession than, in the judgment of the writer, it usually receives.

In the frequent legal issues upon questions of damage to life or limb, and in all of the trials for high crime, the physicians and surgeons are invariably material witnesses upon both sides of the action. During the trial of a fellow-being for his life or liberty, in every locality, human curiosity never fails to develop audiences of extreme proportions, comprising both of the sexes, representing every variety of occupation and grade of intelligence in the vicinity.

The local medical gentlemen, witnesses in the case, become the chief subjects of scrutiny, and of criticism or commendation, as (in the belief or impression of the listeners) they demonstrate while upon the stand; and, in consideration of the fact that laymen judge harshly, as also that many a reputable physician and skilled surgeon may trace the first descending step from lucrative practice to some foolish, unwise, and unnecessary oversight or misconduct before the public, while undergoing the enfilade of a cross-examination in court, it would seem as if the time had arrived when we should awake to the necessity of qualifying ourselves for better protection against such possibilities.

In offering a few examples by way of illustrating the tricks of attorneys, errors of physicians, and ignorance of certain judges in surgical science, while not clothed in the precise language employed in the cases mentioned, nor embodying the examinations entire, we aim to include in substance such portions of the language as are pertinent to our subject; at the same time maintaining the necessary respect for our professional brethren, who were actors in the drama, by the withholding of names, dates, and localities.

CASE I.—The People *vs.* Blank—a trial on the charge of assault in the first degree, to which Blank pleaded insanity. Dr. A. B., an eminent physician and surgeon, who attended the assaulted party, was made a witness for the people. In his direct testimony Dr. B. swore positively that the accused was not insane, and replied with equal firmness to the hypothetical question offered by the defense. Upon the cross-examination, the attorney for the defense, chagrined at the positive attitude of the doctor and his unmistakable eagerness for the success of the prosecution, propounded the following questions:

"Doctor, you swore in your direct examination that the defendant, at the time of committing this act, was positively not insane?"

"Yes, sir; I did."

"Now, doctor, upon careful reflection and consideration of all of the facts—his attempting suicide immediately after the act, etc.—isn't it possible, if not probable, that the defendant might have been insane?"

"No, sir; he was not insane—he was drunk."

"Well, doctor, did you drink with him that day?"

"No, sir; I never drink."

"Did you see him drink anywhere?"

"No, sir; I did not."

"Well, did you detect an alcoholic odor in his breath?"

"No, sir; I wasn't near enough to him for that."

"Then, doctor, I would like to have you tell this jury how in the name of Heaven you knew that this man was drunk."

The doctor failed to explain, but repeated his affirmation that he knew the defendant was drunk. Then followed the question:

"Doctor, are you familiar with the various forms of insanity?"

"I claim to be able to designate insanity from drunkenness."

"Very well, then you must certainly understand the anatomy of the human brain?"

"Yes; I claim that I do."

"Then, doctor, I wish you to tell this court and jury how many blood-vessels are contained in the human brain?"

The doctor replied: "I cannot tell you the number, sir, there are a great many of them."

"What, cannot tell the number of blood-vessels in a man's brain, the most important portion of the brain's structure?"

"No, sir; I can't."

"Well, doctor, if an expert's knowledge of insanity was on a par with your knowledge of the structure of the human brain, you would hardly be willing to send a fellow-being to prison upon such opinion or testimony, would you? Now, doctor, tell this jury how the blood reaches the brain?"

"Why, through the carotid arteries."

"How does it return from the brain?"

"Through the veins, of course."

"On which side of the neck are these arteries and veins?"

"Why, on both sides."

"What, do you swear that the blood does not go up to the brain through the arteries on the right side and return through the veins on the left side?"

"Yes, sir; I do."

"Doctor, are you as positive of this as you are of all of the testimony you have given in this trial?"

"Yes, sir; I am."

"Well, doctor, that's all."

The above questions were so purely ludicrous that no attention was given the matter by either the prosecution or its medical advisers. But in the summing up of the case, much energy was displayed upon this proof of the ignorance of Dr. B. The defending attorney, in the attitude of a conqueror, and with a sweep of his right hand (containing a volume of Wharton and Stille), argued that even a common student of physiology was conversant with this fact, and that every reputable physician of the land would affirm that the blood flowed upward through the arteries on the right side of the neck to the brain, and returned through the jugulars and other veins, on the left side of the neck. No allusion being made, however, to the *whole* truth that the blood also flowed upward on the left, as well as on the right, side, and was returned as well through the right jugulars. The jury and audience were, of course, convinced of the illusory argument, and withdrew from that court scene in astonishment at the surprising ignorance of that expert witness.

CASE II.—In the action of the People *vs.* Blank, under indictment for murder, and a plea of not guilty, the defending attorney drew from the lay witnesses to the autopsy the fact that a common wood saw and a stove shovel were employed in the act of removing the calvarium; also, that with the lifting of the skull the brain was displaced from its cavity. The details of the autopsy were so vividly drawn from these wit-

nesses, and so horribly pictured to the court that the sitting district judge turned his back to the witness-box in disgust, believing at that time that the entire testimony was unscrupulously manufactured for the occasion. But when the unfortunate coroner and his two physicians, who performed the autopsy, were respectively placed upon the stand and forced to admit all that had been detailed by the previous witnesses, the astonishment of the court and the surprise and disgust of the entire assemblage became painfully apparent.

The strong circumstantial evidence in this case secured speedy indictment and promised probable conviction until the autopsy was reached, when the tide of public sentiment, tinged with more or less prejudice, at once disheartened the able prosecuting attorney in its abrupt sway in the direction of the defense. In the summing up of the case, the autopsy was again pictured to the jury, by the defense, in as illusive and ridiculous terms as the attorney was able to command. The result of the trial, of course, was an acquittal of the accused. Subsequent inquiry revealed the facts that one of the surgeons secured a new, finely cut, cabinet saw, which was used at this autopsy, and that the calvarium was pried from the head by aid of the handle of the fire shovel, and that the attachments of the duramater to the calvarium withdrew the brain from its seat in the act of elevating the skull, and that, in reality, the details of the autopsy were, in efficiency, unquestionable.

CASE III.—The People *vs.* Blank, indicted for infanticide, with a plea of insanity. At a session of the commission, which was organized for the purpose of determining the mental condition of the accused, Dr. C. D., of a neighboring county, was produced by the defense as an expert medical witness. On his direct examination the doctor proved himself the medical superintendent of his county hospital, which included a department for the insane. The doctor further qualified as an expert on insanity in the affirmation that he had familiarized himself with the various popular works on the subject. The cross-examination of this expert revealed the fact that the hospital, or retreat, in question was in reality an ordinary county poorhouse. Also, that the expert medical superintendent became the professional attaché of the place by virtue of an appointment and a contract to render such medical service as the inmates from time to time required, and that his salary for such service amounted to about twenty-five cents per day during the year. As a further humiliation to the witness, the district attorney assailed the doctor's knowledge of insanity, in substance, in about the following manner:

"Doctor, you state that you are somewhat familiar with the popular works on insanity?"

"Yes, sir; I have read most of them."

"Doctor, are you familiar with Hammond on the diseases of the brain and nervous system?"

"Yes, sir; I have read the work."

"Have you ever read Steincamp on the diseases of the spinal cord?"

"Yes, sir; I have read some of the work."

"Are you familiar with Bourgero's work on insanity?"

"Yes, sir; I am somewhat familiar with it."

"Did you ever study Larabee on acute diseases of the brain?"

"Yes; I have read it some."

"Doctor, have you ever read McIntyre on puerperal insanity?"

"Yes, sir; I have seen the work and read somewhat of it."

"You consider him a good authority, do you not?"

"Well, yes; pretty good."

"Doctor, have you this work in your library?"

"I think I have, if it has not been borrowed from me, or lost in some way."

"Very well, doctor, that is all."

When the attorney, by way of rebuttal, placed Dr. E. F. upon the stand, and by him proved that all of the above-named authors (save one) were purely fictitious, and that no such works on medical literature ever existed edited by Steincamp, Bourgero, Larabee, McIntyre, etc., which the expert had testified of his familiarity therewith, the extreme humiliation of the witness, and the chagrin of the representatives of the defense in the action, can be better imagined than described.

CASE IV.—G. H. *vs.* the town of Blank. A civil action in the Supreme Court, to recover for fractures of both bones of the right leg, at its lower third, the consequence of the falling in of an unsafe bridge, while plaintiff was crossing in the seat of a heavily loaded vehicle.

In this case the writer appeared as a witness for the plaintiff, having rendered surgical assistance in the care of the fractured limb, and we, therefore, submit a portion of the court proceedings illustrative of certain antagonisms between the professions in trials before the benches of judges possessing only Homœopathic stores of surgical knowledge.

In establishing before the jury the character of the injury, etc., the plaintiff's attorney drew forth the information that the result of the surgical care of the limb, though not perfect, was considered a good average convalescence. This reply drew from the bench the inquiry:

"What, are not the bones now in perfect apposition?"

The witness replied: "No, sir; they are not."

In his address to the jury, this district judge of the Supreme Court of the State of New York, charged in substance, that, though Dr. C. had sworn that the bones were not in perfect apposition, it really required no more mechanical ingenuity and skill to replace and keep those broken bones in place than it would to splice or mend a broken pole or thill to one of their wagons.

Another portion of the examination of this witness included about the following queries from the same bench:

"Doctor, what were your services worth in this case?"

"My bill for services, including livery hire and the supplies which I furnished—"

"What were your *services* worth?"

"Do you inquire the value of my services, exclusive of supplies?"

"No, no; what were your *services* worth?"

"Do you ask as to the value of my services to the patient?"

"Yes, sir.

"My services rendered the plaintiff, in my judgment, were worth $50,000, for they doubtlessly saved his life."

"No, no, no, doctor; I fear that the jury will give but little credence to your testimony; what were your services worth?"

"Sir, I am unable to answer that question in any other light than heretofore attempted."

"Very well, then, we will pass the question."

The desired information was subsequently developed by this query of the plaintiff's attorney:

"Doctor, what was the amount of your bill against

the plaintiff, which was paid to you by him, for your entire care of his case?"

The above discrepancy was but the natural result of the employment, on the part of the judge, of the term services in that unlicensed, broad sense, apparently covering, in his opinion, the precise scope in *our* profession (where the expense of livery hire, apparatus, supplies, etc., must be added to the labor), as in his calling where simply the brain and vocal organs are brought into action in developing results.

In passing from the clinical histories to the remedies for the contingencies, described in the above situations, we beg to submit such suggestions as have occurred to us, as being the most effectual methods of protection to the physician's "stock in trade," his local reputation.

First and foremost, allow us to urge with all possible human emphasis, thorough acquaintance with all of the medical and surgical points obtainable in the case, and then, from one or two of the latest accepted medical authorities, thoroughly qualify upon the probable material questions in the issue. Adhere strictly to the one or two authorities which have been studied, and disclaim any familiarity with all others.

Get up the main anatomical features, and never hesitate to admit that you have forgotten such portions of the study as are not readily recalled; at the same time, remind the audience and jury by a suffix to the reply, that even attorneys are forced to consult their authorities at times.

Secure the favor of the entire court by manifesting a spirit of absolute fairness to both parties in the action, avoiding all prejudice and indication of personal interest in the result of the trial. It is the fair testimony that weighs with a jury, and no reputable attorney will dare to hazard his case in attacking a fair witness.

Avoid technicalities, unless fully interpreted in common English when employed. Witnesses who persist in the use of technical terms, not only displease their hearers, but expose themselves to the charge of being airy or vain.

Weigh carefully the purport of every question from the cross-examiner, and reply with *confidence*, for the witness who habitually hesitates becomes easy prey to the attorneys of the opposition.

Never reply to questions that are so framed as to be doubly construed, but rather prove such fact if any uncertainty exists by demanding a repetition of the question, and then inquiring as to which construction was intended. The compound question is an especial favorite of the shrewd cross-examiner who invariably insists upon replies thereto in the monosyllables of yes or no. These questions are so constructed as to render the reply "yes" proper to a portion, and "no" to the balance of the subject-matter. When thus confronted, the writer habitually conforms to the request of the attorney for replies in monosyllables, and embodies in each of such replies both of the terms "yes" and "no." And when the attorney demands the analysis of this extraordinary response, we charge his question with compound or complex construction and ask for its analysis before replying further.

Prefix replies to mythical and misleading questions with the statement, that in correctly answering such questions an explanation is necessary, and then insist upon your right to render such explanation as will leave the matter perfectly clear, even though you appeal to the court for the privilege.

Avoid the habit of volunteering information tending to effect the issue, beyond that included in the question asked.

Adopt and observe the rule, never to enter the witness-box until you have stationed at the side of your attorney, a medical colleague, who is fully competent to suggest in your re-direct examination such interrogatories as may be necessary to insure the placing of your testimony in its fair and proper light before the court and assemblage.

In the autopsy room permit the presence of none, excepting those who are legally entitled to remain, particularly, if common tools are to be employed in the labor. The meager autopsy outfits of many physicians do not include the saw and chisel, therefore, those operators are compelled to meet emergencies with such means as may be at hand, and while their results may be exceptionally reliable and complete, even though the wood saw and fire shovel are pressed into service, yet a sweeping publication of the fact, before the uninitiated populace, cannot but depreciate the value of the service, as well as the reputation of the operators as skilled and qualified surgeons.

This feeble contribution would be conspicuously incomplete without a word as to the common obstacle to our more rapid progression in the estimation of a thinking public as a class of scientific men, namely, the deplorable conduct of certain physicians, who become ready tools in the hands of unscrupulous attorneys in the perversion of real facts and accepted theories, to their desired dishonest ends. Many physicians hold themselves in readiness for an alliance to that party, in a legal issue, which promises the greater compensation, and when so allied, strip our profession of its hard-earned embellishments by the moulding of well-established truths into theories adaptable to the interests of their employers. Is it then surprising that the integrity of a medical witness, and the sincerity of his testimony, is so frequently questioned in the jury room, when members of the same profession publicly, and under oaths of honor, antagonize one another to the broadest possible expanse upon questions, which to laymen, appear as indisputable facts?

Let us hope that in the future deliberations of this honorable body, while enriching our qualifications for the duties of the table and bedside, such considerations of the functions of the physician as an expert witness will be entertained, as will eventually elevate our noble calling to its merited pinnacle of integrity.

SEVERAL attempts have been made to construct an effective electrical tricycle, and a machine has now been constructed which appears to possess points that entitle it to be considered a practical machine. It is similar in construction to the ordinary tricycle except that it is much larger, and is said to attain a speed of twenty miles an hour. The motive power is a storage battery placed under the seat. This battery will run the vehicle over one hundred and twenty miles at one charge, at a cost of fifty cents.

THE telephone has for some time been used in various hospitals as a means of communication between patients who were suffering from infectious diseases and their visiting friends. It is now proposed that the phonograph be brought into the hospital for the entertainment of the patients, and it is argued that a phonograph in a ward, with a large and constantly renewed supply of cylinders, would be a source of amusement and pleasure to the patients which would admirably supplement the hospital treatment.

The Polyclinic.

PHILADELPHIA HOSPITAL.

Reported by S. T. Buck, M D.

IN patients who have hemorrhoids and who suffer very much, the pain and tenesmus is often due, not to the hemorrhoids, but to rectal ulceration, which should in all cases be carefully looked for.

ŒDEMA OF SCROTUM.

Patient was a man admitted to Philadelphia Hospital suffering with a gonorrhœal bubo, which was of unusual size, and extended over the external abdominal ring. The scrotum was about the size of a fœtal head, not inflamed and pitting on pressure. The swelling seemed due to the pressure of the suppurating glands interfering with the circulation. The dorsal decubitus and incision of the bubo promptly relieved the œdema.

Two cases recently observed of undoubtedly *syphilitic eruption* (secondary) experienced itching, a phase which is not often met with.

AN EXCELLENT FEVER MIXTURE.

℞.—Tincturæ aconiti ..... ♏xx.
Spt. ætheris nitrosi..... f℥iss.
Liq. ammon. acet. .....q. s. ad. f℥iv.
M.—Sig. f℥ij, every two hours.

For *old and indolent ulcers*, washing daily with a solution of carbolic acid, 1-20, gives excellent results. It is antiseptic and a powerful stimulant, producing abundant granulations.

A great improvement on the standard treatment of *pediculosis pubis* with ung. hydrargyrum consists in the application to the parts of a tincture of larkspur, applying with a sponge and mopping thoroughly. One, or at most two, applications is sufficient. Its advantage consists in the fact that it is cleanly and non-poisonous.—*Porter.*

In a case of *acute lobar pneumonia* the pill febricide—

℞.—Quininæ sulph..... gr. ij.
Antifebrin..... gr. ij.
Cocainæ chloaid..... gr. ⅙

—was given with excellent results, the skin becoming moist and the temperature kept within bounds. For a short time the pill was withheld, with the result of the temperature rising, the skin becoming hot and dry, and all the symptoms becoming worse. Upon again administering the medicine the patient improved and the crisis occurred on the sixth day.

In a case of *acute pharyngitis* in a person subject to frequent attacks of this disease, the pillars of the pharynx and the posterior wall were touched with a solution of nitrate of silver (60 gr. to the f℥j) followed by a gargle of

℞.—Potassi chloratis..... ℥ss.
Ext. rhus glab. fld ..... ℥ss.
Aquæ .....q. s. ad. f℥viij.
M.—Sig.

This treatment was followed by a complete cessation of the symptoms within twenty-four hours.

In indolent ulcers and eruptions, particularly those of syphilitic character, the ointment of ammoniated mercury makes an excellent application. The best results were obtained with those ointments made with an animal fat instead of petrolatum, cosmoline and similar preparations.

In a case of *tertiary syphilis*, in which there was extensive destruction of tissue in the mouth and pharynx, from the formation and breaking down of gummas, and in which apnœa was threatened from excessive secretion, the inhalation of the steam from a mixture of equal parts of vinegar and water gave instant relief. As there seemed to be some hysterical element in the case the following was given with marked success:

℞.—Potassi bromidi..... ℥ij. ℈ij.
Morphinæ sulphatis..... gr. ⅔.
Tinct. valerianæ ammon..... f℥j.
Syr. zingiberis,
Aquæ.....āā q. s. ad. f℥ij.
M.—Sig. f℥ij every two hours.

A case of bubo recently treated was traced to the pressure and friction of an ill-fitting and worn-out hernia truss.

MEDICO-CHIRURGICAL HOSPITAL.

ANTISEPTIC TREATMENT OF TYPHOID FEVER.

OF the importance of disinfecting the alimentary canal in typhoid fever, there can be no question. The points to be accomplished by the antiseptic treatment are well known. Of the many remedies employed, the most satisfactory are the sulphocarbolate of zinc (so highly recommended by Prof. Waugh), or the sub-iodide of bismuth, in 5-grain doses, every three hours.—*Godfrey.*

Tincture of strophanthus, in 10-drop doses, quickly relieves the asthmatic attacks occurring in Bright's disease.—*Godfrey.*

PRURITUS VULVÆ.

Pruritus vulvæ results, generally, either from a discharge from the uterus and vagina, from diabetes or from structural lesion of the vulva. Being an effect, the cause should be ascertained. For the local treatment, applications of a solution of bichloride of mercury will prove the most serviceable.—*Godfrey.*

JEFFERSON MEDICAL COLLEGE.

IN a case of acute tonsillitis, treated at the clinic at Jefferson College Hospital, the following treatment was given, viz.:

Locally the patient was ordered to use a gargle of quaiac and hot water alternately; and internally—

℞.—Ext. jaborandi fl..... ♏x.
Quininæ sulph..... gr. iij.
M.—S. ter dii.

Dr. Stelwagon advised the following lotion in a case of chronic ulcer:

℞.—Acid. boracici ..... f℥ij.
Acid. carbolici..... f℥ss.
Glycerini ..... f℥iss.
Alcoholis ..... q. s. f℥viij.
M.—S. Apply to the affected part.

A clinician, in speaking to the class of a case of ataxic paraplegia, said that the power of resistance was rendered so weak that anything lowering the vital forces, *e. g.*, influenza or pneumonia, however slight, would prove fatal. He gave the following in regard to treatment: Arsenic, nux vomica, combined with electricity and a nutritious diet.

At a recent hospital clinic the following prescription was given in a case of acute rheumatism:

℞.—Potassii iodidi..... gr. v.
Potassii acetat..... gr. x.
Vin. colchici radicis..... gtt.x.
Syr. zingiberis,
Aquæ .....q. s. āā f℥j.
M.—S. ter die.

GO SLOW.

THE prevalence and intensity of the epidemic is extraordinary. Never before has any medical fad taken so profound a hold upon the public. From every quarter patients are rising from their death-beds, and, with the consumptive's never-dying hope, hastening to the new Mecca. By thousands they crowd the hotels of Berlin, struggling for the privilege of being treated at any price. Hundreds of physicians have left their work and are gone on the same profitless journey. The vast majority of the latter could accomplish more by quietly staying at home and attending to their business. At Berlin, they cannot obtain speech with Koch; nor can the lymph be had for love or money, entreaty or influence. Still, as the journey is in many instances simply an advertising dodge, and it would never do to go so far and come home without any lymph, it is greatly to be feared that the law of demand and supply holds good, as usual. Lymph at any price is an imperative necessity; money is to be had for lymph; lymph is to be had for money. It is good to be the first in the field; the early fruit brings the best prices; and it is better to be at sea in a rudderless boat than to be lymphless when the patients are thronging the halls of our rivals. So that we are not surprised to hear of lymph whose pedigree cannot be traced back to Koch, except with the dubious qualitative "said to be;" and of doctors who left Berlin in despair at their inability to obtain any lymph, but landed here with enough to inoculate thousands.

Meanwhile, what is the attitude of the medical schools and journals? As the leaders of medical thought, the proper guardians of the public against the heresies and false doctrines that arise so often, we have a right to expect their influence to be exerted in the right direction. And few can doubt what this is. To moderate undue excitement; to point out the limitations of the new methods; to keep the unfortunates at home who have nothing to expect from the lymph. Instead of that, they appear to be breaking their necks in a mad race to see who can do most to enhance the excitement. Special bulletins, long lists of patients treated, newspaper articles, illustrated with cuts representing the illustrious professors performing the operation on lovely and interesting patients: all helps on the good work. The only question is: Who can get the most advertising out of it? And in this laudable emulation, the eminent medical leaders and the notorious McCoy and Wildman meet on the same track and appear to be running neck and neck. Nevertheless, there is not a doubt but that this course will pay.

Let us look back a few short years. The Bergeon gas treatment was introduced; and several men who stood high in the ranks of the profession lent the sanction of their names to it. The same scenes were enacted; money was poured out like water; hope ran high; the eminent men made money by handsful. The conservative men who were not carried away by the enthusiasm of the moment proved to be right, and were badly left. The enthusiasts were wrong, but were made rich. Now, the same farce is being enacted over again; and we suppose it will so continue to the end of time.

For all this wretched business Robert Koch is not responsible. Nothing can be more clearly put than the limitations he has made to the use of his remedy. The evil lies with those who persist in making of it what Koch persistently declares it is not, *i. e.*, a remedy for consumption *per se*. While the medical journals and colleges have not directly affirmed this, they have done much harm in stimulating the popular interest, by their bulletins, etc.

The simple fact is that Koch has announced the discovery of a substance whose powers he limits to the cure of lupus, a disease not very common in America; of external or surgical tuberculosis, and possibly of pulmonary tuberculosis in its earliest stages. He distinctly states that advanced cases of tubercular phthisis have nothing to hope for from this remedy. The dangers of the remedial agent, and the permanency of the cure, are not yet satisfactorily studied out; but the rapidly multiplying deaths reported, apparently due directly to the lymph; and the reports of reappearance of lupus in cases pronounced cured, show that even in the most carefully selected subjects there is neither safety in use, nor certainty of cure. The limited time which has elapsed since the discovery of the remedy, makes it impossible to say as yet that any complete or permanent cure has been obtained. And yet on this slender foundation what a fairy palace of hope has arisen!

The interest in Koch's discovery lies mainly in the future. His remedy, as yet, amounts to but very little, if it does all he believes. But it opens a door for the future, through which vast possibilities may be seen. He, and others trained in his scientific methods of investigation, may make this discovery the beginning of a new era in medicine. Or, like Jenner's discovery, it may lie fallow for a century or two, till the general intelligence of mankind has advanced to a point where further progress becomes possible.

A DISAVOWAL.

WE print in another column a letter from the editor of the *Journal of the American Medical Association*, in which he disavows the attack upon Surgeon-General Hamilton which recently appeared in the *North American Practitioner*, the organ of the firm of Charles Truax & Co., of Chicago. Our readers will, of course, understand that the article recently appearing in our columns upon this matter was based upon something more than suspicion. But one cannot be held responsible for the acts of even his most intimate friends; and it is with a feeling of relief that we print Dr. Hollister's prompt disavowal.

The attack upon Dr. Hamilton was as unjust as it was malicious. No member of our profession in America has done as much for the public weal as has the Surgeon-General of the Marine Hospital Service. In this capacity he has stood between the country and the invasions of epidemic diseases, with their untold possibilities of evil. His good work during the yellow fever visitation in Florida would hardly need to be recalled, were it not that men's minds are not tenacious of benefits received; and nine-tenths of the public never knew how well their interests were then cared for. Not content with showing how thoroughly efficient was the organization of his department in that emergency, Dr. Hamilton set the example of pluck to his colleagues by placing himself in the heart of the dangerous district.

The splendid organizing ability of Dr. Hamilton was also shown in the Ninth International Medical Congress, in a way that is best appreciated by those who had the opportunity of comparing the management with that of the Berlin Congress, where the Secretary-General's incapacity has prompted the benevolent suggestion that he was probably insane. As to Dr. Hamilton's management of the Journal, during the short time he controlled it the standard was assuredly equal to that of his predecessors, to say the least. He is now out of the management, charged with duties of infinitely greater importance, and occupies a position in which he should have the moral support of the united profession; that the public welfare may be subserved, and because his work has shown him to be deserving of such support.

Those whose experience has been limited to civil life often fail to comprehend the importance of public support to men in responsible official positions. Just such malevolent attacks as the one under discussion, made by irresponsible persons, or even anonymously, may prove a serious matter to a public official, and throw great obstacles in the way of the discharge of his official duties. Captain King has finely illustrated this in his last book, "An Army Portia;" a book which every one should read who feels tempted to find fault with a public officer without really knowing anything about the circumstances.

OUR impression as to the spurious nature of the lymph now being used in this country is confirmed by the fact that the characteristic reaction described by Koch has not been manifested. Somebody in Berlin is perpetrating an outrageous swindle. Lymph should not be trusted unless it comes directly from the Government officials. As to the dangerous qualities of the lymph there is, however, no question; the death of Dr. Jacobi's patient demonstrating the activity of the agent employed. This case, of tubercular meningitis, was one in which, according to Laplace's report, the use of the lymph was unjustifiable.

All the lymph sent out by Libbertz is put up in blue or brown vials, containing one drachm each. These are imbedded in blocks of wood about three inches square. The manufacture is supervised by Koch's son-in-law, and its sale is controlled by Libbertz, so closely that even Koch himself was unable to secure a vial. Up to December 12, but sixty two vials had been sent out of Germany; but two of which came to America. The above information is from a source whose reliability we fully endorse.

Annotations.

THE following cable dispatch appears in *The American Journal of the American Sciences* for January; sent by Prof. Ernest Laplace, of the Medico-Chirurgical College, a private letter from whom appears in another column. Dr. Laplace's intimate personal relations with Prof. Koch, and his thorough training in bacteriology under Koch and Pasteur, render this by far the most important report that has yet been made by any of the Americans visiting Berlin:

"So far as we can learn, the material which is used by injection for the cure of tuberculous disease is itself a product of the action of the tubercle bacillus upon a culture medium, the composition of which has not yet been made known, under conditions which are also still unrevealed. It probably contains, in addition to the *toxine* or *toxines* to which its activity is due, a minute quantity of cyanide of gold, as a protective against possible contamination with the bacilli themselves. 'Koch's lymph,' as it is called, is prepared for use in the following manner: One gramme of the lymph, with 9 grammes of a 2 per cent. carbolic acid solution, constitutes the first (10 per cent.) dilution, from which a second (1 per cent.) dilution is made in a similar manner—9 grammes of carbolized solution being added to 1 gramme of the diluted lymph; and from this again a third ($\frac{1}{10}$ per cent.) dilution is made—1 gramme of twice-diluted lymph to 9 grammes of carbolized solution. This third dilution, then, contains 1 part of the lymph in 1,000 parts of the preparation, so that a dose of 1 gramme of fluid contains 1 milligramme of the lymph. As a rule, the patient is subjected first to this dose. Should no effect be produced by repeated doses, the amount is increased to a dose not exceeding 6 centigrammes. Koch always makes use of a freshly-prepared solution.

"Introduced into the stomach the remedy has no effect; it is, therefore, injected subcutaneously by means of the small syringe suggested by Koch for bacteriological work; the site of injection is the skin of the back between the shoulder-blades and the lumbar region, or, more recently, in the gluteal region. From three to eight hours after the injection, the effects begin to be manifested. They vary greatly in different subjects, and are said not to occur at all unless tuberculosis is present. The presence or absence of 'reaction,' then, is assumed to be a diagnostic sign, and this test was made use of by Gerhardt and

von Bergmann to discriminate between cancer and tuberculosis of the larynx; and more recently between tuberculosis and syphilis of the palate. Upon the same principle, a patient who no longer manifests reaction, after receiving the maximum dose of the remedy, is assumed to be cured, though, for the present, Dr. Koch and his assistants very wisely speak of provisional cure only, as sufficient time has not yet elapsed to test its permanency.

"Among the provisional cures are cases of lupus, of tuberculosis of the larynx, of incipient phthisis, and of white swelling in children. Children stand the treatment well if care be taken not to begin with too large a dose.

"Reaction is manifested both by local and constitutional symptoms: the latter comprise pain in the limbs, fever, sometimes chill, nausea, and vomiting; in phthisical cases cough and dyspnœa; and in a few cases sensorial disturbances, such as somnolence and delirium. The fever may rise as high as 40° or 41° C., in which event great cardiac depression, and even collapse, are likely to occur. Sometimes the temperature suddenly falls to 36° or even 35.5° C. During the next day, however, there is a slight elevation of temperature to 37.8° or 39° C., called by Koch the 'secondary reaction.' The temperature again sinks below normal when the second stronger injection is given, which is followed by high fever, as before.

"The local manifestations consist in swelling and discoloration of the affected tissues, which finally necrose, and are either spontaneously expelled, or must be removed by surgical means.

"In cases of lupus, the local reactions, which are easily observed, have been very striking. The affected tissues become very red and swollen, surrounded by a raised border sharply defined, usually dark-red in color, in some cases whitish, and varying from the breadth of a few millimeters to that of a finger.

"After the subsidence of the fever, the swelling of the lupus-tissue gradually decreases and disappears. The lupus-spots are covered by a soft deposit which desiccates into a crust; the crusts falling off, clean, red cicatrices are left. Of one case, Feilchenfeld says that the pathological tissue seemed to have been removed as with a punch.

"If local reaction is observed in sites previously thought to be healthy, it is held to indicate the presence of unsuspected tuberculous disease. In many cases of lupus this has been a marked feature of the progress of the case toward recovery.

"As already stated, the symptoms of the reaction vary greatly in different individuals and in different forms of tuberculous disease.

"A slight punctiform rash sometimes appears over the whole of the body. In some cases a slight amount of albuminuria has been noted.

"The physiological disturbance from a given dose is greatest in acute cases. As recovery progresses, the dose necessary to produce reaction must be progressively increased, until finally, when the largest dose—6 centigrammes—fails to produce reaction, cure is assumed to be complete. Cases of surgical tuberculosis begin to react only under a dose of 5 milligrammes or more. Until now the injections have been administered on alternate days, so that the effects might be better studied; but Koch maintains that the more rapid and intense the treatment, the more rapid and safe must be the cure, and the intervals between the injections will probably be diminished.

"The injections must be supplemented by the best possible hygiene and measures calculated to promote nutrition generally. Especially is this necessary in cases of suppurative joint-disease. In these cases, too, the 'cure' progresses slowly, and surgical interference is requisite to complete it.

"The action of the lymph seems to be the destruction of tuberculous tissue, and the constitutional disturbances seem to be correlated with this process. The more extensive the lesions the more pronounced are the disturbances; and hence the smaller the initial dose which will excite reaction, but the greater number of repetitions of the injections, and the larger the final dose required, before the reaction ceases to be manifested. Extreme caution is evidently necessary to avoid dangerous constitutional reaction in cases of widely-disseminated tuberculosis; and where the locations of the lesions are such that the local reaction might jeopardize life, the treatment is contra-indicated. Thus, at least three conditions may be enumerated in which recourse to the method must be pronounced unjustifiable:

"1. Advanced pulmonary tuberculosis.

"2. Severe laryngeal tuberculosis.

"3. Tuberculosis of the brain or meninges.

"But even in apparently mild cases there may lurk unsuspected dangers. A man who had for a short time exhibited symptoms of pulmonary tuberculosis, received in three days two injections, the first of 2 milligrammes, and the second of 3 milligrammes, of the lymph. Reaction was excessive, and five days later he died.

"Slight cavities were found at one apex, both lungs were hepatized, and were infiltrated throughout with miliary tubercles. It is conjectured that the hepatization was the effect of the local reactions at the numerous foci offered by the disseminated miliary tubercles: this theory assumes the previous existence of these latter, but who shall say that they were not produced by the injections? The time is not too short to have permitted this. At all events, death seems to have been directly due to the treatment.

"In a private conversation held with Koch recently, he said that though the Government now reserves the right of preparing the lymph, in a short while all applicants would be supplied. It is my impression that Koch desires the method to be firmly established before any doubts could be cast upon it by impure or otherwise imperfect lymph, which source of danger is now eliminated by the stand taken by the German Government. At present it is impossible to procure the article, and more than five thousand applications have already been filed for it. Hundreds of doctors from the world over are returning home satisfied with the results demonstrated, but with only the hope of receiving the lymph at some future time."

IMMATURE CATARACT.

DR. RICHARD KALISH, in an article on The Absorption of Immature Cataract by Manipulation Conjoined with Instillation, thus sums up his conclusions, after having cited various cases:

My conclusions are: 1. Further investigations are necessary before a decided opinion can be expressed as to the result of this treatment in mature cataract. 2. Immature, uncomplicated cataract can be benefited to the reacquisition of reading power, that is, to good, useful vision. 3. Incipient cataracts and those which have but passed into a state of immaturity can be entirely absorbed. 4. This being so, the sooner a cataract comes under treatment the better the result obtained. 5. The effect produced by my method of manipulation, conjoined with instillation, is permanent.—*Medical Record.*

A PHYSIOLOGICAL THEORY.

THE human body is not a kingdom where one queen soul sits enthroned in perfect solitude, but a colony of psychic individualities, which are absolutely distinct, but are all subordinate to a chief, the cerebral Ego, which so far as they are concerned is a *primus inter pares.* This thought of physiological and psychic plurality is confirmed by our internal experience. We know that at every moment we are performing mental acts without being aware of them, we are unconscious of our own subjective state. Now, unconscious subjectivity, unconscious sensation, for example, is a contradiction in terms; but the contradiction is explained, when I remember that though a certain sensation of mine may not be experienced by me, that is, by the Ego which is the psychic centre of my whole being, it is felt by one of my other Egos, by the psychic principle, which presides over that unit of my organism which is the seat of the sensation. This theory of human *polyzoism* and *polypsychism* will hereafter, it may be added, give birth to new doctrines, psychological, moral, and eschatological.

—Durand, *Literary Digest.*

MARRIAGE AS A REMEDY.

A VERY sensible editorial on the subject in the *Journal of the American Medical Association*, says:

There is no restriction of marriage to-day except in the pronounced idiotic and raving maniac. No one is so diseased or deformed, or crippled, or defective in mind or morals, but may marry and become a parent of degenerate, helpless children, as far as the law is concerned. While this is a sad reflection on the intelligence and civilization of to-day, it reveals a field of reform which medical men of all others should occupy at once. All medical writers are unanimous in condemning marriages between defective and disordered persons, and yet public sentiment would not sustain to-day any special laws of restriction. Obviously this is one of the great fields of prevention of disease, that both medical men and legislators will occupy in the near future.

Never counsel marriage as a remedy or means of relief for neurotics or persons of defective heredity. Elevate and dignify marriage as a means to raise the race in every way from its childhood age. Although *Utopia* is far away, there are evident signs of progress towards it, and when marriage becomes a subject of strict legislation, a long stride forward will be taken.

ANTI-VIVISECTION AND THE ROYAL SOCIETY.

THERE was a significant outbreak of feeling at the Royal Society, when Dr. Hopkinson, who had received one of the medals of the society for his researches in electricity and magnetism, alluded to the subject of vivisection. He was returning thanks for Dr. Ferrier and the other medalists. Dr. Ferrier had well won the medal for his researches into the localization of brain function, with a view to surgical and therapeutic purposes. Dr. Hopkinson, alluding to the splendid work of Pasteur and Koch, said that Dr. Ferrier's researches showed that, with anything like similar conditions, the discoveries of Pasteur and Kock would be equaled by men in our own country; but in this respect we are hindered. We do not live "in a free country." If a few more great discoveries have to be studied, as a favor, in Paris or in Berlin, and our *savants* have to be sent there for the purpose, Englishmen will be apt to doubt whether they are acting kindly by man or beast in tying the hands of their best investigators, who have done more to mitigate suffering than the Society for the Prevention of Cruelty to Animals itself. Dr. Hopkinson said that had he been hampered in his experiments as physiologists and physicians are, he could never have made the discoveries which Sir William Thomson says affect the whole range of physicial science.—*Lancet.*

THE PRESENT STATUS OF THE TUBERCULOSIS QUESTION.

WRITING to the *St. Louis Courier of Medicine* on this question, Dr. L. Bremer says, among many other good things;

When we assume that the tubercular predisposition and scrofulosis denote only a constitutional anomaly which favors the invasion of tubercle bacillus, and if, in addition to this, we adopt Metschnikoff's theory, according to which in bodies built after the type called the phthisical habitus, there is an inherent weakness of the leucocytes to destroy, *i. e.*, to digest the bacteria productive of phthisis, it seems intellible enough that many escape the disease that are placed under the same morbific surroundings, to which others succumb. No theory, indeed, is more captivating and appeals more strongly to our understanding, than this theory of phagocytism introduced into the pathogenesis of infectious disease by the Russian investigator. Even those not grounded in biology and pathology will find it quite easy of comprehension that the white blood corpuscles resembling so closely in all respects the amœba, should, like this unicellular animal, embrace, *i. e.*, eat, smaller organisms than itself and digest them. The foreign invaders, the bacteria, are hunted up as it were, by the soldiers, the white blood corpuscles swarming throughout the animal's organism, swallowing every bacterium they may come in contact with. On the aggressiveness and digestive powers of the leucocytes, the fate of the whole organism depends, in case of such inimical invasion. If they triumph in the struggle with the enemy, the host is saved, the intruders vanquished, *i. e.*, disease is prevented. In other words, immunity from tubercular disease is due to the ability of the leucocytes to attack, swallow and digest the otherwise pathogenic bacteria.

HEALTH OF AMERICAN GIRLS.

THERE is no question as to the telling effect of nerve wear on our women, and in my opinion the essential causative factor to which the ill-health of the American girl must be referred is functional neglect (or ignoring of her functions) and over-brain work; over-exertion of the nerves and emotions, with imperfect development of the muscular system, an inharmonious development and exertion, physical, mental and moral.

The most persistent period of nerve and vascular excitement is that of developing womanhood, when for months the system is in a period of unusual activity, and consequently the highest susceptibility, which does not cease as speedily as we see its outward tokens disappear. Then follow the cyclical changes of mature life, varied by the higher waves of active reproduction.

The functional wave slowly rises until it reaches flood height, with an increase of nerve activity and vascular tension, accompanied by a rise of temper-

ature, as Mary Putnam Jacobi tells us, of from one-tenth to eight-tenths of a degree F., and it is during the decline of this wave that the depletion takes place, when the distended vessels rupture and nature relieves herself, the temperature steadily sinking, but not reaching the normal until after the cessation of all external symptoms.

In considering the initial causes of disease in their effect upon woman, we must analyze not alone this one function, but we must consider the entire being of woman, that we may apply the proper standard, and that we may not measure her capacity for labor, mental or physical, or her powers of endurance, with those of man, woman—the woman of our civilization—cannot be properly compared with man; she is differently organized, differences of many kinds exist—the most obvious, of course external and anatomical. Form and shape differ; her organism is a different one; individual organs are more vascular and more nervy; she is more emotional, more readily exhausted, less able to bear continuous and prolonged application; more blood is produced, the circulation is more active, so also the respiration. The period of puberty is shorter and more marked, and the last stages of development are reached at an earlier period in life.

Engelmann, *Medical Mirror.*

HEREDITY AND RESPONSIBILITY.

JUST as the theories of evolution and spontaneous generation threatened at one time to sap the foundations of religious belief, so at present there is a growing disposition to strain the logic of heredity, and thereby discount the sum of human responsibility. Man, it is argued, is an organization, the resultant of the organization of his ancestors; that organization rules him by inexorable laws; if it has been gouty, he must have the gout; if it has been tainted with insanity, he must be a lunatic; if it has been vitiated by a passion for gambling, he must be a gambler. He has no escape from the "tyranny of his organization" This is only partially true. The incapacity of insane minds to distinguish between right and wrong; the inability to resist temptation which we ourselves at times experience are to some extent inherited weaknesses, but the blame attaching to them is not entirely due to our ancestry; we are more or less capable of resisting them, and by exercising our power of resistance we may subdue them. Heredity in a word is a stern reality, but not an absolute tyrant. All sane men and sane women are to some degree morally responsible.

That deadly form of fatalism, the belief that the tyranny of organization cannot be evaded, has often a powerful influence in precipitating insanity where there is a hereditary tendency to it; but that it is possible to resist and eventually conquer the tendency may be inferred from the theory of evolution itself; for it is a part of that theory that favorable variations are naturally enduring, while variations that are unfavorable are prone to become extinct, from which it follows that living a life in harmony with the laws of physiology consumption, gout and insanity may through time be effectually stamped out.

The moral which may be deduced from these premises is that the destiny of each one of us is ruled by his own individual resolve and effort. As an incentive to such effort we should bear in mind that posterity will some day speak of us as we do of our ancestry, and that it may in turn disclaim responsibility for the sins of the fathers, and accuse us of propagating brain at the expense of muscle, of breeding idiocy, insanity and nervous diseases by living at too high pressure, and of overstraining young brains to make them prodigies of learning; we should, in short, reflect upon the everlasting truth that "no man liveth unto himself."—*Literary Digest.*

THE TREATMENT OF EPILEPSY BY DIETING.

CERTAIN drugs act upon the nervous centres so as to control to some extent this tendency to discharge. How is this done? The answer is twofold. First, these drugs may act so as to fix the nitrogen compounds, and render them more stable, less likely to part within nitrogen, less ready to discharge. Second, these drugs may act by preventing the formation of these unstable nitrogen compounds. This, I believe, is the real explanation. Under the use of the bromides the molecules take in nitrogen less rapidly, and consequently do not become so unstable or explosive.

If this is the case, can anything be done towards the reduction of the share of nitrogen by feeding the patient after some fixed plan? To this I answer, yes. Take young dogs and cats, and feed them too freely upon meat, and you can make them—especially the dogs—very subject to fits, similar to ordinary epilepsy in the human subject. Acting on this line, I have been in the habit of making my epileptics become strict vegetarians. Eggs, lean meat, red fish flesh, cheese, peas, beans, and all nitrogenous articles are cast off. The amount of nitrogen entering the system is reduced by this means to the lowest possible quantity. Under this dietary it is much more difficult for the nervous system to build up these unstable molecules, full of nitrogen, ever ready to fall into new combinations, and produce discharge of energy, while these changes are being effected. By persistently reducing the daily consumption of nitrogen there is not such a free formation of the catabolic molecules, the discharge of which is necessary for the production of the convulsive seizures of true epilepsy. This method of treating these patients has been of very great value in my hands. It would seem, however, that the restitution of the diet to an almost non-nitrogenous vegetable one is of most use in those extremely catabolic conditions met with in the status epilepticus. It is in this variety of the disease that we have such poor results from the administration of drugs. I have treated some epileptics on the above food plan and without drugs, the health being better than when taking the bromides, without the restitution in diet. I would not go the length of saying that epilepsy is a food diathesis, yet I am strongly inclined to think that it tends this way. Not all those who use meats and liquors to excess become gouty; nevertheless we do not doubt that gout is a food diathesis thus produced.

With our epileptics there is an extremely unstable condition of the nervous molecules. This unstable state can be greatly lessened by lessening such food-supply of the molecules as that from which the excess of nitrogen is obtained.

—Ferguson, *Therapeutic Gazette.*

"THE doctors is allways a gettin' up a lot of new names for the diseases that flesh is heir to, and the druggists is a inventin' new nostrils to cure 'em. There's Mrs. Jones has tonsors on her throat, and Mr. Jones has ulsters in his. Miss Smith has hermitage of the lungs, an' her mother has two buckles on her lungs."

Letters to the Editor.

YOUR editorial of December 13 does a manifest injustice to the supervising editor of the *Journal of the American Medical Association*, which you surely will correct when you are possessed of the following facts: 1. The *Journal* and the *Practitioner* are distinct journals, in every particular. 2. The editor of the *Journal* had had no communication with the editor of the *Practitioner* whatever, on the subject referred to; did not know that such an article was to be printed, and only now knows of it as it appears in print.

As innocent of any relation to the matter as is the editor of THE TIMES AND REGISTER, it is presumed that the amend will be cheerfully made.

Very respectfully,

Supervising Editor

Jour. Amer. Med. Ass'n.

THE WEST INDIES.

YOUR correspondent of last week who signs himself "W.," suggests that some "enterprising newspaper or publishing house" in the West Indies should take a few lessons in advertising from the State of Florida, and thus render my work of making the islands known, needless.

In all the West Indies there is not such a thing as a publishing house, except one of very limited capacity in Jamaica, and another small one in Havana, neither of which has shown the slightest sign of energy in pushing their respective islands. There are no "enterprising newspapers" anywhere, and the writer has found it necessary to publish all his books and articles here in America, where push and energy are appreciated, because they are understood.

If the West Indies, with their wonderful beauty and great value as sanitaria, were to be left to themselves to become known, it is the writer's opinion that it would never come to pass.

Very truly,

W. F. HUTCHINSON, M.D.

Book Notices.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS. Vol. 8, No. 2. November, 1890. The contents of the present volume of this valuable series are as follows: Treatment of Uterine Affections by Massage. By DR. EUGENE ARENDT. Cosmetics; a Treatise for Physicians. By DR. HEINRICH PASCHKIS. Affections of the Stomach in Diseases of the Male Genital Organs. By DR. ALEXANDER PEYER. Published by Wm. Wood & Co., 56 and 58 Lafayette Place, New York.

TREATMENT OF HEMORRHOIDS, AND OTHER NON-MALIGNANT RECTAL DISEASES. By W. P. AGNEW, M.D. San Francisco, Cal.: R. R. Patterson, Printer, 429 Montgomery street. 1890.

This is a plea for the treatment of all forms of hemorrhoids by the injection of a mixture of carbolic, tannic, and salicylic acids, borax, and glycerine. In spite of its bad spelling and grammar, the book is worth reading, in that it gives the experience of a man who has actually practised the method he advocates, even after he has weighed the objections of its opponents. After reading his book we are inclined to think that Kelsey abandoned the injection method too readily.

The Medical Digest.

BOILS MICROBOUS.—In May, 1879, a man working in the laboratory of Pasteur ([13]) was troubled with boils, which reappear at short intervals on various parts of the body. Pasteur collected the pus from a number of these boils and sowed it in sterilized infusions, and each time a microbe, formed of little spherical points connected in pairs, and frequently united in clusters, was seen to develop. The cultivating liquid was sometimes infusion of fowl, sometimes of yeast. New observations were made upon other patients afflicted with boils, and each time the same parasite was found. He concludes that every boil contains an ærobic microbe, and to it are due the local inflammations and the formation of pus.

—Drury, *Cincinnati Lancet-Clinic.*

INFANT FEEDING. — Dr. Sachapelle gives, in *L'Union Medicale du Canada*, the following table to serve as an approximative rule in the feeding of infants. It will be noted that the amounts allowed are larger than those recorded by Dr. Kate Parker as the result of her investigations at the New York Infant Asylum, and quoted by J. Lewis Smith, in his book on children:

AGE.	INTERVALS BETWEEN MEALS.	NUMBER OF MEALS IN 24 HOURS.	MEAN QUANTITY AT EACH MEAL.	MEAN QUANTITY IN 24 HOURS.
First week.	2 hours.	10	1 ounce.	10 ounces.
First to sixth week.	2½ hours.	8	1½ to 2 ounces.	12 to 16 ounces.
Six to twelve weeks, and if needful until five or six months.	3 hours.	6	3 to 4 ounces.	18 to 24 ounces.
At six months.	3 hours.	6	6 ounces.	36 ounces.
At ten months.	3 hours.	5	8 ounces.	40 ounces.

—*Weekly Med. Review.*

IPECACUANHA IN LABOR.—While the accelerating action of ergot in cases of lingering labor is universally known and acknowledged, there is another drug which, so far as I am aware, is not noticed in works on midwifery, and which yet is capable in such cases of rendering signal service; I allude to ipecacuanha. Not only in cases of rigid cervix, where possibly it might be considered to act in a similar manner to antimony, but in cases of simple inertia in either first or second stage, it is a potent instigator of uterine contraction.

In the course of general practice extending over many years, I invariably carried a bottle of vinum ipecacuhanha in my midwifery bag, and rarely, if ever, gave a dose of ergot in the first stage of labor. Time after time on coming to a confinement case where the pains had been feeble and inefficient, or had totally ceased, two or three 10 or 15 minim doses of the wine at intervals of ten minutes have been followed in a surprisingly short time by energetic uterine action, with a rapid termination to the labor. It never produces the quasi-tetanic contraction so often met with as the result of ergot, the pains continuing

to recur regularly just as they do in natural labor, but with greater force and at shorter intervals. Conviction of the value of the drug for this purpose induces me to give my experience of it, believing that its merits will be recognized by any who choose to give it a trial.—Draper, *Brit. Med. Jour.*

STRICTURE OF THE URETHRA IN THE FEMALE.—The occurrence of stricture of the urethra is, in my experience, of extreme rarity; it may therefore be of interest if I relate the following case:

The patient, M. A. L——, aged thirty-two, married eleven years, had suffered for eight years from pain and difficulty in passing water. Seven years before coming under my care, in the Chelsea Hospital for Women, she underwent an operation for the relief of the stricture, in St. George's Hospital, without, however, deriving any permanent benefit. No history could be traced of her ever having had any vaginal discharge. She had, however, passed blood and gravel in the urine, accompanied by great pain, twelve years previously, that is, I should say, one year previous to her marriage. On examination, it was found to be impossible to pass the catheter into the bladder; she was therefore placed under ether, and a uterine sound was finally passed through a small stricture into the bladder. The urethra was then gradually dilated with Hegar's dilators to the size of a No. 12 catheter. During the process of dilatation, the dilators could be felt strongly gripped by the stricture. The day after the operation, the house surgeon was able to pass a No. 8 catheter, which gave rise to considerable pain afterward. The next day, a No. 10 catheter was passed. This was repeated every morning. As the stricture could always be felt lightly grasping the catheter, it was considered advisable to dilate the urethra further. The patient was again placed under ether, when I dilated the urethra up to 8 of Hegar's dilators. From this time she was able to pass water without inconvenience. She was instructed to pass herself a No. 8 catheter, at least once a week. In this case the cause of stricture remains obscure. No evidence could be discovered of any gonorrhœal infection. She had never been pregnant. Nor was there any history of injury to the bladder or urethra. The fact of her having passed gravel and blood, some years previous to the formation of the stricture, goes equally for nothing.

—Fancourt Barnes, *Prov. Med. Jour.*

INTESTINAL OBSTRUCTIONS.—The conclusions, then, that I have arrived at from my experience are as follows:

1. Obstruction of the intestines, the result of constricting bands or volvulus, are always met with either in the small intestine or the sigmoid flexure.

2. The most common cause of bands is old peritonitis, local or general. Meckel's or other diverticula may be the cause of constrictions of the bowel by snaring or twisting.

3. The predisposing causes of volvulus consist in elongation of certain segments of the intestine, abnormal length of the mesentery, adhesions, or unequal peristaltic action.

4. The higher in the intestine the obstruction, the more severe usually are the symptoms.

5. All cases of obstruction should be treated by early abdominal section, and, if possible, reduction of the constricted portion of the intestine, by dividing constricting bands or untwisting a volvulus; that is, if the gentle insufflation of hydrogen gas per rectum fails to effect reduction.

6. In all cases where the intestine is very distended, it should be freely incised and its contents evacuated.

7. In all cases in which the constriction is irreducible, lateral anastomoses by approximation discs should be practised so as to exclude permanently the seat of obstruction from active fæcal circulation.

8. In cases where gangrene has taken place in the loop of constricted intestine, it should be excised, and the portion of intestine above and below the seat of constriction should be united by lateral anastomoses by approximation plates, the divided ends being invaginated into themselves.

9. All bands and diverticula should be removed when practicable at the time of the operation; in the case of volvulus, if the mesentery is abnormally long, it should be shortened.

10. That enterostomy, or the formation of an artificial anus, should never be performed, unless it is found to be absolutely impracticable to re-establish the continuity of the intestinal canal by enterorrhaphy, or by means of lateral apposition as described, on account of the collapsed condition of the patient, or other cause.—Jessett, *Prov. Med. Jour.*

TOLERATION IN MEDICAL ETHICS — We take the following from an editorial in the *New York Medical Times*. Although the tendency of the age is certainly towards toleration, and while theoretically every man has a perfect right to his own opinions and to act in accordance with them as long as they do not interfere with the rights and privileges of his neighbors, there is still enough of the old spirit in the medical profession to make it very unpleasant for the man who preaches toleration. Dr. Guernsey has been in somewhat the position of Mr. Pickwick, when he attempted to separate the fighting editors, and both united in pummeling the peacemaker:

"We are in receipt of a private letter from a professor in a leading 'regular' college, from which we extract the following, as an indication of a feeling which is rapidly gaining ground. He says:

"'For the regular colleges to refuse to regraduate those having a degree from the Hahnemann Medical College, of Philadelphia, on the same terms that they will those of other regular colleges I, for one, deem an act of folly. They ought to be glad of the opportunity of having the young men, at the very outset of their careers, discountenance creeds and adopt the methods of science.'

"We are in receipt also of a letter from a professor in a homœopathic college which says: 'I believe the day will come when the profession will be educated up to the point when sectarian distinctiveness will be dropped.'

"Within the last few months we have conversed with a large number of recent graduates of homœopathic colleges, and every one of them has complained of the position in which they are placed by their sectarian diploma.

"The graduate of a distinctively homœopathic school is sadly handicapped on many accounts, and so long as the *great majority* feel as they do in respect to sectarian designation, no change for the better can be expected.

"Is it right and just toward a student to place him in a position where he may be embarrassed, particularly at a critical moment? Suppose a graduate of a homœopathic college desires to enter the U. S. army or navy, he will find himself embarrassed at the very outset! Preceptors should bear these facts in mind, when advising a student to enter a medical school!"

PROGRESS IN ABDOMINAL SURGERY.—Perhaps no branch of our art has had a greater attention paid to it, or made more satisfactory progress in the last ten years than abdominal surgery. In this paper I have nothing new to offer the profession, my endeavor being simply to enumerate some of the changes in the mode of management by which we have gained a high degree of perfection, as is evidenced by our present statistics. But our advance is not limited to results alone as compared with the work of surgeons at that time, for we now perform operations with impunity every day that they never attempted; or if they did it was more as a result of mistaken diagnosis. There is hardly any limit to the field of the surgeon in these days; it includes injury or disease of every organ in the abdominal cavity, and even the old time feared peritoneum itself, while ten years ago the knife of the operator was almost exclusively restricted to ovariotomy alone. Wounds of the various organs are now cut down upon, washed clean, stitched and dressed, with comparative ease and the results are marvelous. Even where the wound cannot be found (as in intestines it sometimes occurs), the assistance we offer nature by thorough cleansing and drainage greatly increases our chances of success.

—Thompson, *Weekly Med. Review.*

TREPHINING FOR EPILEPSY. — There are three main indications for trephining in epilepsy that hold good, provided medical treatment or the removal of peripheral irritation by other methods fails to cure or relieve.

1. In the distinctly tragmatic epilepsies following depressed fractures and other lesions of the skull.

2. In the traumatic epilepsies in which the only visible lesion consists of a scalp wound that is sensitive or tender, and upon which pressure develops either an aura, vertigo, or an epileptic seizure.

3. In all epilepsies, whether traumatic or not, in which the character and development of the seizures is such as to indicate a definite motor area as the seat of a cortical lesion.

The contra-indications, he went on to say, were, in brief, those that might be applied to cases of such long duration as to lead to marked mental degradation; to cases in which from the first the seizures had been general and sudden; to cases where the general symptoms indicated an extensive cerebral degeneration, and to cases where, in addition to any or all of these conditions, there was nothing in the symptoms or history of the case to indicate a definite or circumscribed lesion of the cortex that could be reached and removed.—Minor, *Boston M. and S. Jour.*

DEATHS FROM ANÆSTHETICS.—Dr. Robert Kirk, of Glasgow, in a letter addressed to the *British Medical Journal*, says:

The continued prevalence of deaths from these agents renders of pressing importance the inquiry whether every possible source of danger from them is known to the entire profession. What is the cause of the primary syncope, which may be produced, not only by chloroform and methylene, but even in some rare cases by ether? In "A New Theory of Chloroform Syncope, Showing How the Anæsthetic Ought to be Administered," I have ventured to offer a new explanation of the catastrophe which, unless it can be refuted, deserves serious consideration. According to this theory, this form of syncope is not caused by chloroform in the blood. On the contrary, it is maintained that there is not a trace of the poison there when the syncope occurs. It is urged that it is due to the violent reaction which ensues in the circulation when the vapor is allowed to escape from the lungs at too early a stage of the inhalation—a process which occupies not much more than ten seconds if the patient is allowed to breathe fresh air during the first minute or two. This reaction is characterized by an extremely rapid action of the heart, with a liability to terminate in syncope. This violent reaction proves that the vapor was previously exercising a powerful influence in the lungs and respiratory tract—an action probably attended, through reflex mechanism, with inhibition of the heart. If there be any truth in this view, therefore, it follows that the administrator who allows his patient to breathe fresh air for fifteen or thirty seconds before deep anæthesia is reached, incurs the danger of reaction and syncope. It is the presence of a sufficient amount of chloroform in the blood which prevents the reaction which would otherwise ensue when the vapor leaves the lungs.

DIET FOR DIABETICS.—

ALLOWED.	PROHIBITED.
All kinds of meats (except liver). Poultry, all kinds of game.	Liver.
All kinds of fish, fresh or salt, sardines.	Sugar, in any form.
Oysters.	Starch, in any form.
Eggs in any style (without addition of flour, starch, or sugar).	Sauces containing flour, sugar, or starch.
Fats and fatty meats.	Cakes of all kinds.
Butter, cheese.	All cereals, such as cracked wheat, oatmeal, mush, cerealine, etc.
Soup (without flour or the prohibited vegetables).	
Celery, cabbage, cauliflower, string-beans, asparagus, lettuce, spinach, mush-rooms, radishes, cucumbers (green or pickled), young onions, water cresses, slaw, olives, tomatoes.	Potatoes (either Irish or sweet), corn, carrots, turnips, hominy, parsnips, beans, peas, beets, rice.
Graham bread, rye bread. Occasionally stale light (white) bread.	White bread, corn bread, white biscuits.
Acid fruits, such as oranges, lemons, apples, plums, cranberries, currants, cherries, strawberries, gooseberries (sweetened, not with sugar, but with saccharine and sod. bicarb.).	Pears, peaches, grapes.
Gelatine (without sugar).	Sweet jellies.
Almonds, walnuts, Brazil nuts, hazelnuts, filberts, pecans, butternuts, cocoanuts.	Chestnuts.
Salt, vinegar, pepper.	
Drinks: Coffee, tea (without sugar), skim-milk, cream, soda-water (without syrup), mineral waters of all kinds, but especially vichy.	Malt liquors, beer, ale.
Claret, Rhine wine.	

—Lewis, *Weekly Med. Review.*

HINTS ON TREATMENT OF ULCERS OF THE CORNEA.—Some surgeons apply nitrate of silver to indolent ulcers, but this is a proceeding very rarely called for; and when sharp stimulation is demanded, I have found the use of the actual cautery (considerably below red heat), more beneficial and less dangerous.

Again, in cases of corneal ulceration, accompanied by blepharospasm and fissure, atropine *alone* is sometimes disappointing; and, short of dividing the tissues at the affected canthus, other local means may be employed, *e. g.*, a seton in the temple, or a good blister an inch from the fissure. When no fissure exists, painting the brow every other day with tincture of

iodine may suffice to allay spasm. But such treatment without atropine is practically valueless.

The cases in which atropine would be considered harmful, and in which eserine is so often substituted, are those in which the tension of the globe is decidedly above normal; or in which perforation is threatened by a deep ulcer, in consequence of increased pressure from within. Admitting that atropine may be here out of place, paracentesis of the anterior chamber, either through the base of the ulcer, or at some other point, will probably give more relief, and yield better results than treatment by eserine. Eserine is largely employed in the treatment of hypopyon ulcer; here, again, atropine and paracentesis of anterior chamber are more satisfactory. It is only in case of failure with atropine that I fall back on eserine.

Some patients are peculiarly susceptible to the influence of atropine, and very soon show signs of the characteristic "irritation." Cocaine in castor oil—a five per cent. solution—may here advantageously replace the toxic agent until all signs of atropism have passed away, when it may be again ordered, but in reduced strength.

When a corneal ulcer produces severe pain, hot belladonna fomentation (one drachm of extract to a pint of hot water) may be applied on a pad four or five times a day—one quarter of an hour at a time—instead of atropine drops. But a little atropine ointment (four grains to the ounce) should be placed between the lids at night.

As an additional measure in very painful cases, three or four leeches to the temple often act like a charm. With all corneal ulceration there is *more or less* photophobia, and bright light must, therefore, be excluded. Pads and bandages are much more injurious than useful, for they keep the eye hot, and act very much like poultices. A large paper or card shade over both eyes is the very best method of keeping off light.

—A. St. Clair Buxton, in *The Hospital Gazette.*

Treatment of Puerperal Fever.—The present unanimity of treatment of this disease is curious. Most articles on the subject seem to wind up with curetting the uterus and bichloride irrigations. This monotony of treatment is broken, however, by differences of opinion relative to the percentage of the bichloride.

The young man must feel as though he had not discharged his duty to his patient, unless he has scraped the uterine cavity and irrigated the same with bichloride. I do not criticise the curetting of the uterus, when it is necessary, but I do not think it is so very often necessary, and that frequently it is harmful rather than advantageous.

In regard to bichloride of mercury irrigations, I must say, I have been unfortunate in not having seen any remarkably good results from their use. I do not criticize the cleansing of the uterine cavity, but I think we have a better agent in iodine.

Iodine may not be the most powerful germicide, but its wide range of curative powers, in removing inflammations, healing sores, and alterative action, makes it the better agent.

Bichloride of mercury is, undoubtedly, a good antiseptic for hands and instruments; they will be less colored by it than by iodine—then, again, the hands and instruments differ widely from the diseased parts of the patient.

Treatment is determined, in great measure, by the tissue system which is predominently affected. There may be inflammation of the mucous membrane of the genitals only, or there may be inflammation of the uterine parenchyma, or inflammation of the peritoneum, covering the uterus and contiguous parts, or a phlebitis with pyæmia or a septicæmia, or an absorption of ptomaines with toxic effects—all these conditions are to be met with good judgment.

Dorr, *Buffalo Med. and Surg. Jour.*

Diphtheria.—It is submitted that there is good reason for thinking that the diphtherial poison—when it enters the patient's body in an extreme dose—kills him outright (with the symptoms of malignant diphtheria) by paralysing the heart, by its action on the vagus, in exactly the same way as an overdose of nicotine would do. In the heart-failure of blood-poisoning there certainly are two ways at least whereby the weakness of the heart can come about; either the special poison acts on the nervous apparatus of the heart, or the state of the blood is so altered for nutrition that the muscular fibre of the heart gets feebler and feebler, and a time comes when it refuses to act at all—the heart stopping full of blood in diastole. The latter condition is probably the predominant cause of the asthenia of sapræmia: both possibly have some, but I think the former far the larger share, in causing stoppage of the heart in malignant diphtheria. And the ante-mortem clots which observers have found in the chambers of the heart in cases of diphtherial syncope are doubtless due to the weakened action of the heart, and would themselves serve as a fresh source of embarrassment.

Also, when smaller doses of the poison are taken (as in uncomplicated cases such as have been related above), a gradual depression of the heart's action takes place, due likewise to the action of the poison on the vagus, and death occurs by syncope. And, as would be the case in nicotine-poisoning, whether death were brought about by one fatal dose or by several smaller ones, no appreciable pathological change has been found in the nerves in either the malignant or the more ordinary cases of syncope in diphtheria. Later on in the disease, indeed, in special persons (just as in lead- or alcohol-poisoning), but, as it is contended, simply as a *continuation* of the same process, this irritation of the vagi and other nerves produces definite traces of its presence by the inflammation of their branches. Lead-poisoning affects generally nerves whose rôle is not the immediate preservation of life; luckily, perhaps the same remark will apply to alcohol-poisoning in its more chronic forms, but when, as with diphtheria, a poison acts almost directly on the heart, it is obvious that many must get killed by it who would otherwise have suffered from diphtherial paralysis; in other words, that personal idiosyncrasy acts as much in determining the immediate or remote affects of a dose, as it does in making the person susceptible to the disease at all. And it is noteworthy in this connection that the paralysis is more common in adults and in those who have been hard worked mentally and bodily.—E. Mansel Sympson, in *Practitioner.*

On Splints.—Speaking of fractures of the lower end of the radius, Dr. John B. Roberts says:

The danger of many of the splints advocated for this fracture is due to the non-recognition by their respective inventors of the curved or arched shape of the palmar surface of the lower third of the radius. The dorsum of the bone when covered with the tendons is straight, but the palmar surface is curved. It is readily understood, therefore, that the application of any straight splint (such as that called Bond's splint) to the palmar surface of the broken radius has

a tendency to displace the lower fragment upward again, as soon as the bandage which retains the splint in position is applied. A straight splint may, however, be applied with propriety to the back of the wrist. I have used with satisfaction two or three pieces of whalebone held in position by a strip of adhesive plaster. Any rigid article, such as a piece of steel or wood, half an inch wide and five or six inches long, will answer the purpose. The truth is, however, that in a person of ordinary intelligence, who will avoid subjecting the bone to severe strains, there is no need of any splint or rigid support. Exceptions to this rule may perhaps be found in the case of refractory children and of ignorant or stubborn adults. The fact that these persons are liable to use the hand at an early period, and in such a way as to cause a *slight* risk of displacement of the fragments, is evidence of the simplicity and painlessness of the injury and of the satisfactory manner in which union takes place, if reduction has been properly effected.

—*Medical News.*

Further Researches by Koch.—Sir Joseph Lister has returned from a visit of a few days to Berlin, where he has had the opportunity of witnessing the action of Koch's treatment of tuberculosis; and on Wednesday in King's College Hospital he related his impressions regarding it. He spoke of the effects produced by this treatment upon tubercular disease as simply astounding, both in its curative effect and its diagnostic value. He combated the statements which had appeared from time to time in certain publications, to the effect that it was impossible for the dead portions of tissue resulting from the treatment to be got rid of by other than surgical means; he stated that provided these portions of tissue were preserved from septic agency, they need not necessarily be separated from the living body, as they were eliminated by absorption in the same manner as a catgut ligature. There was no reason to suppose that the fact of this tubercular tissue being destroyed would make it incapable of absorption. He compared the action of Koch's fluid with that used by Pasteur in the case of anthrax, an injection of which gave complete immunity from this disease, and he hoped that Koch's future researches would result in showing the remedy capable of acting on human beings so as to give them complete immunity from tuberculosis.

There was another line of research from which he hoped for good results in the direction of immunity. Through the kindness of Prof. Koch he had the opportunity of visiting the Hygienic Institute of Berlin, and of seeing most beautiful researches being carried on in that institution, of which he was the inspiring genius. Those researches were now going on, and fresh facts were accumulating day by day. They had not yet been published, and he was not at liberty to mention any details, but there could be no harm in saying that he saw, in the case of two of the most virulent infectious diseases to which man is liable, that the injection under the skin of a small quantity of a material, perfectly constant in character—an inorganic chemical substance as easily obtained as any other article in the materia medica—cut short these two formidable diseases in the animals in which they were performed. These same animals were rendered incapable of taking the disease under the test of the most potent inoculations. He suspected that before many weeks were passed, if it should be found that the same results could be produced on man—though experience of what was known of the different behavior of Koch's fluid in guinea-pigs and in man makes this a matter of uncertainty until tested by experiment—the world would be startled by the magnificence of these researches, which would be recognized on every hand.—*Lancet.*

Clinical Observations on some New Pharmaceutical Preparations.[1]—Dr. R. Harvey Reed, Mansfield, Ohio, says:

"Every age in medicine and surgery has had its fanatics, who seemed to live for little else excepting to ride some particular hobby to death; whilst, on the other hand, every age has had its old fogies who would rather perish than turn an inch to the right or left of the old time-worn rut of their forefathers.

"The hundreds of worthless 'new remedies' that are placed before the profession for their patronage from year to year, is enough to disgust them with all new remedies. It seems to me that many of our manufacturing chemists spend the bulk of their time seeking for something that is *new*, regardless of its real merits or value.

"If only they can strike the profession with a 'new remedy' of some description or other, they are perfectly happy.

"But with all these criticisms we must admit there is now and then a new remedy comes to light which has real and lasting merit, which in a large degree atones for the defects of many of its worthless compeers."

Then after referring most favorably to the non-irritating preparation of cascara sagrada, prepared by Mr. J. Le Roy Webber, Ph. G, the author makes the following statement as to his experience with pancrobilin:

"In this direction, however, we have another 'new remedy' which has gradually ingrafted itself into my good graces, which is becoming more and more permanent the longer I use it. This is what is known as 'Pancrobilin' and is a combination of pancreatin and bile, and placed upon the market in the form of a liquid and a pill, of which two I consider the latter more preferable.

"In cases where there is a diminished quanity, or even an absence, of these natural products, especially the bile, resulting in the distressing complication of intestinal or duodenal indigestion, I have found this preparation of decided value by assisting the intestinal digestion until the normal functions of the liver and pancreas, but especially the former, could be established.

"In constipation attended with flatulence, the result of an inactive liver, I have found this remedy of great value, promptly relieving the flatulence, and producing natural colored stools of a normal consistency, in place of the pale ash colored fæces, or the dry, hard scybala, of the chronic dyspeptic.

"After a careful trial of some three years in a variety of cases affected with constipation resulting from congestion of the liver, and in cases in which there is an atonic condition of the coats of the bowels resulting in intestinal indigestion, I am frank to say that I know of no two remedies that will give as prompt relief to these conditions as the ones under consideration.

"In the one class of cases the pancrobilin supplies the intestine with an artificial supply of bile and pancreatin, which digests the food that otherwise would not be digested, thus giving relief until the real difficulty with the liver can be overcome. In the other class of cases the cascara sagrada tones up the intestine, increases the secretions, which in turn facilitate digestion, and relieves the constipation."

---

[1] Read before the Thirty-fourth Quarterly Meeting of the North Central Ohio Medical Society, held at Mansfield, Ohio, September 26, 1890.

Medical News and Miscellany.

THE cholera still rages in Spain.

A SUPPOSED case of leprosy has appeared at, and disappeared from, Defiance, Iowa.

DR. THOMAS G. BRINKLEY has removed from Reading, Pa., to Sinking Spring, Berks Co., Pa.

EDINBURGH has recently been a prey to an epidemic of typhoid fever which had its origin in the pollution of the milk.

THE first death from the effects of Koch's lymph in New York is that of an infant suffering with tubercular meningitis; a patient of Dr. Jacobi's.

MILWAUKEE doctors are said to enjoy the exclusive possession of a specific for "black diphtheria," imported from Germany by a druggist, and employed with "astonishing success."

IT is stated that a meeting of the Board of Trustees of the *Journal of the American Medical Association* will soon be held, in order to take action upon the question of removing the *Journal* to Washington.

DRS. GIBBES AND SHURLY, of Detroit, are alleged to have discovered a "sure cure" for consumption; acting even in the later stages. It is said to be the outcome of work on a different line from that of Koch.

THE London Hospital Sunday Fund Collections for the past year amounted to over $200,000. Of this sum ninety per cent. came from church collections. The expenses amounted to $9,000; and the balance was distributed among 169 institutions.

IN the Chamber of Deputies at Paris, last week, M. Despres proposed that the Government restore the nuns to their former position as hospital nurses. M. Constans, Minister of the Interior, opposed the proposal, and argued in defence of lay nurses.

AT the last M. B. examination of the University of London, nine female candidates went up, of whom every one passed—five in the first grade, and four in the second. At the same time, sixty-nine male candidates presented themselves, of whom fifty-two were successful.

PROFESSOR KOCH has been elected honorary fellow of many medical societies in Europe, *e. g.*, at Vienna, Prague, Buda Pesth, and elsewhere. The freedom of Wollstein, in Posen, where he was in practice, has been bestowed on him, and a tablet points out the house he occupied.

SOUTH LAKEWOOD PARK, N. J., Dr. J. B. de Lery's electric city, received very handsome endorsements from the New York *Times* and *Tribune* in last Sunday's editions. Each paper devoted about a third of a column to the new city, which is progressing finely in the line of disposing of sites.

DR. F. O. VINCENT last week entered the residence of his separated wife, in Fresno, California, and shot her through the heart. He was arrested and became unconscious on the way to jail, having apparently taken poison. Dr. Vincent graduated at Cooper Medical College, in 1878.

DR. C. C. VANDERBECK has established at 216 Leavenworth street, San Francisco, a private home hospital, called The Hygeia. All classes of cases, excepting contagious diseases and the insane, are admitted, and the patients may have the attendance of their own physician when desired. It deserves the confidence of physicians and the public.

—*Pacific Med. Journal.*

IN a physician's office: "I say, doctor, I wish you'd fix me up something for my stomach trouble. I've got something inside that first comes up and then goes down and then comes back again, and—faught! it makes me sick to think of it."

Doctor: "You don't mean to say that you've accidentally swallowed an elevator?"

THE widow of General Custer says that he was the first of American army officers to experiment on the rattlesnake as an entrée. His cook prepared the dish under protest, and as the general was eating the dainty he saw the alarmed negro cautiously peering in through a crack of the tent, doubtless expecting to see his master drop down in a fit.

VITAL statistics from some of the largest English towns show a slight percentage of decrease of mortality in the week ending December 6, over the three weeks previously. The following were some of the causes of death: 172 from measles, 64 from scarlet fever, 58 from diphtheria, 51 from diarrhœa, 42 from whooping-cough. 48 of the diphtheria cases were in London.

THE Chicago Medical Association met at the Grand Pacific, Monday evening. The meeting was largely attended. The first paper was an exhaustive treatise, entitled: Studies in Chronic Retro Ocular Neuritis, by C. M. Hansen, M.D. Patients were exhibited in connection with the paper. Dr. Hansen was followed by Dr. L. T. Potter with an instructive and entertaining article on the Influence of the Mind upon Disease.

THE deaths in St. Louis, during November, numbered 576, representing an annual death-rate of 15.02 per 1,000. The principal causes of death were: phthisis, 62; heart disease, 37; convulsions and trismus, 33; old age, 32; accident, 23; malarial, 22: hepatitis, 21; bronchitis, 30; pneumonia, 18; typhoid fever, 16; diphtheria, 15; croup, 14; scarlatina, 5; cancer, 15; marasmus, 15; gastro-enteritis, 15; Bright's disease, 15.

SANITARY administration means not only personal comfort and health in the family, but economy to the State and family. Two hundred and fifty thousand lives lost, three million cases of sickness and $20,000,000 in money are traced, in one decade in England alone, to neglect of sanitary care. The sword and musket are terrible ministers of death, but even in armies, where battles kill one person, disease kills at least three.—*Hon. Erastus Brooks.*

THE city of Memphis, Tenn., formerly noted for its bad sanitary condition, has been improved in an extraordinary degree, partly by an improved system of sewerage, but chiefly by a supply of pure water. The city water was formerly drawn from wells and cisterns, and later from Wolfe river, but in both cases the surface water which yielded the supply was of very poor quality and contained many impurities, making it unfit for use and a constant cause of disease. Recourse was at last had to artesian wells, and it was found that at a depth of about 350 feet there was a stratum of water bearing gravel, the water being of exceptional purity and abundant in quantity. It is believed that any future increase in requirements can be met by increasing the number of wells.

An Italian professor has, after many experiments, come to the conclusion that "whitewash," freely applied on the walls of dwellings, is one of the most effectual destroyers of microbes and fever germs we have. It is satisfactory to know this, as it shows that our grandfathers, whose ideas of disinfecting dwellings began and ended in whitewashing, inside and out, were not groping in the dark after all.

The directors of the Dental Protective Association held a meeting at the Grand Pacific Hotel, December 17. The meeting was called for the purpose of putting a stop to the abuses practised against dentists by patent medicine organizations which blackmailed dentists and made them pay a royalty on medicines. The following directors were elected: Dr. J. M. Crouse, Dr. E. P. Swaine, and Dr. P. W. Brophy.

A case of scarlet fever at Sioux Falls, S. D., will probably cause trouble. A few days ago Mrs. D. W. Culp died of that disease. Health Officer Brown later learned incidentally that another case had developed in the family and instituted a quarantine. He has just discovered that the case has been in the hands of Christian scientists, who ignored his notice and sent other children of the family to school. The superintendent of schools was notified yesterday and the Christian scientists will probably be prosecuted.

The experiments of Dr. Charcot, in Paris, have been cited to prove the magnet's mesmeric value. This celebrated specialist did obtain some striking results with a sensitive hypnotic subject under the influence of a magnet. Dr. Charcot not long after repeated the same experiments with the same subject, using, however, a dummy magnet made of painted wood, instead of the real one he had used before. He obtained the same hypnotic results, showing very clearly and positively that magnetism had "nothing to do with the case."

The danger of hypnotism in affording criminals the means of escaping from the legal consequences of their acts, is exemplified in the trial of Gabrielle Bompard, just completed in Paris. A more cold-blooded murder never was committed; and now the woman who lured the man to her den, and placed the fatal rope around his neck while lavishing feminine endearments upon him, seeks to make the court believe that she was at the time in the hypnotic state, and controlled by her accomplice. The result has shown that French courts are not as credulous as jurors in this country.

A patent floating disinfectant, which has recently come into use, appears to possess the three very essential advantages of efficiency, simplicity of application, and uniform solution. A mixture of carbolic acid and other disinfectants in a solid form is so prepared that it will float in water. This melts slowly in the water, and is always visible and accessible. The uniform rate of solution adapts it specially for use in closets. All that is necessary is to place a block of it in the water cistern supplying the closets. All danger of blocking up the pipes is avoided, as the disinfectant is always on the top of the water.

Patents, etc., on medical subjects, issued December 16, 1890:

Ammonia-still	F. Kaiser	Knoxville, Tenn.
Atomizer	J. Schoetti	Brooklyn, N. Y.
Capsule press	F. W. Perry	Philadelphia, Pa.
Draft-tube for effervescing drinks	W. P. Clark	Medford, Mass.
Liniment	D. Meinen	Warrenton, Tex.
Device for facilitating pills	J. Yates	London, England.
Syringe	E. Bartsch	San Francisco, Cal.

TRADE-MARKS.

Liquid perfumery. (The words "Sweet Chimes")	French, Richards & Co	Philadelphia, Pa.
Liquid perfumery. (The words "White Musk")	French, Richards & Co	Philadelphia, Pa.
Pine essence for external use in disease. (The word "Pumiline")	G. & G. Stern	London, England.
Remedy for hay-fever. (The word "Peshall's")	G. L. Wilms	Jersey City, N. J.
Medicated tablets for female diseases. (The words "Oak Balm")	G. L. F. Hager	South Bend, Ind.
Remedy for epilepsy and other nervous diseases. (The representation of a fountain and landscape; the words "Samaritan Nervine," and the motto "In God we trust")	S. A. Richmond	Tuscola, Ill.
Remedy for small-pox. (A monogram of the letters "J. L. S.," and the signature of "Jose Leandro Suasnavar" written across it)	J. L. Suasnavar	New York, N. Y.
Lime-water preparations. (The word "Anticidine")	T. Metcalf & Co	Boston, Mass.

TO CONTRIBUTORS AND CORRSEPONDENTS.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.
